exit

Quit the CLI session

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The exit command ends the current CLI session.

Examples
The following example ends the current CLI session:

```
cluster1:~> exit
Goodbye
```

history

Show the history of commands for this CLI session

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.
Description
The `history` command displays the command history of the current CLI session. A numeric ID precedes each command. Use this number with the `redo` command to re-execute that history item.

Examples
The following example displays the command history of the current CLI session:

```
cluster1::> history
  1  vserver show
  2  man volume show
  3  volume delete -vserver vs0 -volume temporary2
  4  volume modify { -volume temp* } -state offline
cluster1::> redo 3
```

Related references
`redo` on page 2

**man**
Display the online manual pages

**Availability:** This command is available to cluster and Vserver administrators at the `admin` privilege level.

**Description**
The `man` command displays the manual page of the command you specify. If you do not specify a command, command displays the man page index.

**Parameters**

```
[text] - Valid CLI command
```

The command for which you'd like to see the manual page. The syntax of the command is the same as the command itself. The `man` command supports abbreviations and tab completion of the command name.

**Examples**
The following example displays the manual page for the `storage aggregate create` command.

```
cluster1::> man sto aggr cre
```

That example could also have been fully specified as:

```
cluster1::> man storage aggregate create
```

**redo**
Execute a previous command

**Availability:** This command is available to cluster and Vserver administrators at the `admin` privilege level.
Description
The redo command re-executes a command that has been executed previously in the current CLI session. Specify a previously run command using:

- A string that matches part of a previous command. For example, if the only volume command you have run is volume show, enter redo vol to re-execute the command.
- The numeric ID of a previous command, as listed by the history command. For example, enter redo 4 to re-execute the fourth command in the history list.
- A negative offset from the end of the history list. For example, enter redo -2 to re-execute the command that you ran two commands ago.

Parameters
[<text>] - String, Event Number, or Negative Offset
Use this parameter to specify a string, a numeric ID from the command history, or a negative number that identifies the command to be re-executed.

Examples
The following example re-executes command number 10 in the command history:

```
cluster1:/> redo 10
```

set on page 4

set

Display/Set CLI session settings

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The set command changes attributes of the user interface.

Parameters

[-privilege <PrivilegeLevel>] - Privilege Level
Use this parameter to specify the privilege level of the command session. Possible values are:

• admin - Used for routine system management commands
• advanced - Used for infrequent, dangerous, or complicated commands
• diagnostic - Used for detailed diagnostic commands that are used only by support personnel

[-confirmations {on|off}] - Confirmation Messages
Use this parameter with the value on to specify that the interface prompt for confirmation before executing potentially dangerous commands. Use this parameter with the value off to specify that the interface not prompt for confirmation, even before potentially dangerous commands execute. The default setting is on.

[-showallfields {true|false}] - Show All Fields
Use this parameter with the value true to specify that the interface display all field columns when displaying tabular output. Use this parameter with the value false to specify that the interface display only selected columns. The default setting is false.

[-showseparator <text>] - Show Separator
Use this parameter to specify the characters to use as the field separator. The field separator is used between field columns when -showallfields is set to "true". The separator can be from one to three characters in length. When specifying the separator, enclose it in quotation marks ("). Set the separator to one or more spaces to disable this feature.

[-active-help {true|false}] - Active Help
Use this parameter with the value true to specify that pressing the question mark (?) key is sufficient to execute a help request. Use this parameter with the value false to specify that you must press the Return key after the question mark key to execute a help request. The default setting is true.

[-units {auto|raw|B|KB|MB|GB|TB|PB}] - Data Units
Use this parameter to specify the default units used when reporting data sizes. Possible values are:

• auto - Auto-scale data size for human-readable output
• raw - Bytes without unit designation
• B - Bytes
• KB - Kilobytes
• MB - Megabytes
• GB - Gigabytes
• TB - Terabytes
• PB - Petabytes

The default setting is auto.

[-rows <integer>] - Pagination Rows ('0' disables)

Use this parameter to specify the number of rows that can be displayed in the current CLI session before the interface pauses output. If you do not set this value, it adjusts automatically based on the actual height of your terminal. If the actual height is undefined, the default number of rows is 24.

Setting this value manually disables auto-adjustment. Specify zero (0) to disable pausing.

You can also set this value using the rows command.

[-vserver <text>] - Default Vserver

Use this parameter to specify the name of the Vserver to use as the default value for the -vserver parameter of commands.

[-node <text>] - Default Node

Use this parameter to specify the name of the node to use as the default value for the -node parameter of commands.

[-stop-on-error {true|false}] - Stop On Error

Use this parameter with the value true to specify that continuing commands should stop if they encounter an error. Use this parameter with the value false to specify that continuing commands should continue if they encounter an error.

[-prompt-timestamp {above|inline|none}] - Display Prompt Timestamp

Print the current date and time as a part of the prompt. The possible values are

• above - print the timestamp using the system timestamp format on the line above the remainder of the prompt.
• inline - print the timestamp using the system timestamp format at the beginning of the line with the remainder of the prompt.
• none - do not print the timestamp.

The default value is none.

Examples

The following example sets the privilege level to advanced.

```
cluster1::> set -privilege advanced
Warning: These advanced commands are potentially dangerous; use them only when
directed to do so by NetApp personnel.
Do you wish to continue? (y or n): y
cluster1::*>
```

The following examples cause all columns to be shown in output rows, with a comma used as the field separator.
cluster1::> set -showallfields true
cluster1::> set -showseparator "," 
cluster1::> network port show 
node, port, role, link, mtu, autonegotiate-admin, autonegotiate-oper, duplex-admin, duplex-oper, speed-admin, speed-oper, flowcontrol-admin, flowcontrol-oper, mac, up-admin, type, ifgrp-node, ifgrp-port, ifgrp-distr-func, ifgrp-mode, vlan-node, vlan-port, vlan-tag, Node, Port, Role, Link, MTU, Auto-Negotiation Administrative, Auto-Negotiation Operational, Duplex Mode Administrative, Duplex Mode Operational, Speed Administrative, Speed Operational, Flow Control Administrative, Flow Control Operational, MAC Address, Up Administrative, Port Type, Interface Group Parent Node, Interface Group Parent Port, Distribution, Create Policy, Parent VLAN Node, Parent VLAN Port, VLAN Tag, node1, e0a, cluster, up, 1500, true, true, full, full, auto, 1000, full, none, 00:0c: 29:90:20:e9, true, physical, -, -, -, -, -, -, -, node1, e0b, cluster, up, 1500, true, true, full, full, auto, 1000, full, none, 00:0c: 29:90:20:f3, true, physical, -, -, -, -, -, -, -, node1, e0c, data, up, 1500, true, true, full, full, auto, 1000, full, none, 00:0c: 29:90:20:fd, true, physical, -, -, -, -, -, -, -, node1, e0d, data, up, 1500, true, true, full, full, auto, 1000, full, none, 00:0c: 29:90:20:07, true, physical, -, -, -, -, -, -, -, node2, e0a, cluster, up, 1500, true, true, full, full, auto, 1000, full, none, 00:0c: 29:2e:b6:62, true, physical, -, -, -, -, -, -, -, node2, e0b, cluster, up, 1500, true, true, full, full, auto, 1000, full, none, 00:0c: 29:2e:b6:6c, true, physical, -, -, -, -, -, -, -, node2, e0c, data, up, 1500, true, true, full, full, auto, 1000, full, none, 00:0c: 29:2e:b6:70, true, physical, -, -, -, -, -, -, -, node2, e0d, data, up, 1500, true, true, full, full, auto, 1000, full, none, 00:0c: 29:2e:b6:80, true, physical, -, -, -, -, -, -, -,

The following example shows how to create a prompt with a timestamp.

cluster1::> set -prompt-timestamp above

[2/25/2016 16:38:38]
cluster1::>

rows on page 3

top

Go to the top-level directory

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description

The top command changes the current working directory of the command prompt to the top-level command directory.

Examples

The following example returns the command prompt from the storage aggregate directory to the top-level directory:

cluster1::storage aggregate> top
cluster1::>

Related references

storage aggregate on page 667
**up**

Go up one directory

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

**Description**
The `up` command, which can also be specified as two dots (`..`), changes the current working directory of the command prompt to the directory that is up one level in the command hierarchy.

**Examples**
The following example takes the command prompt up one level from the *storage aggregate* directory:

```
cluster1::storage aggregate> up
cluster1::storage>
```

---

**autobalance commands**

Balance resources across the cluster

**autobalance volume commands**

Balance Infinite Volume used capacity across the cluster

**autobalance volume rebalance commands**

Rebalance Infinite Volume capacity across the cluster after files are created.

**autobalance volume rebalance show**

Display Auto Balance Volume progress for an Infinite Volume

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *advanced* privilege level.

**Description**
The `autobalance volume rebalance show` command displays information about Auto Balance Volume operations for an Infinite Volume. The command output depends on the parameter or parameters specified with the command. The `autobalance volume rebalance show` command is only supported for Infinite Volumes.

**Parameters**

```
[[-fields <fieldname>, ...]]
```

This specifies the fields that need to be displayed.
If this parameter is specified, the command displays information about all entries.

`-vserver <vserver name>` - Vserver
If this parameter is specified, the command displays information about capacity balancing for each Infinite Volume and storage service on the specified Vserver.

`-volume <volume name>` - Volume Name
If this parameter is specified, the command displays information about capacity balancing for each storage service on the specified Infinite Volume.

`-storage-service <storage service name>` - Storage Service
If this parameter is specified, the command displays information about capacity balancing for the specified storage-service.

`-state <Auto Balance Volume state>` - State
If this parameter is specified, the command displays information about operations in the specified state.

`-progress <text>` - Progress
If this parameter is specified, the command displays information about operations with the specified progress.

`-transferred (<integer> [KB|MB|GB|TB|PB])` - Amount Transferred
If this parameter is specified, the command displays information about operations with the specified amount already transferred.

`-target (<integer> [KB|MB|GB|TB|PB])` - Target Amount
If this parameter is specified, the command displays information about operations with the specified target amount of data to transfer.

`-transferred-percent <percent_no_limit>` - Percentage Transferred
If this parameter is specified, the command displays information about operations with the specified percentage of the transfer complete.

Examples
The following example displays information about all operations on the Vserver named vs0:

```
cmd> autobalance volume rebalance show -vserver vs1

<table>
<thead>
<tr>
<th>Vserver</th>
<th>Volume</th>
<th>Storage Service</th>
<th>State</th>
<th>Target</th>
<th>Percent Transferred</th>
</tr>
</thead>
<tbody>
<tr>
<td>vs0</td>
<td>repo_vol</td>
<td>-</td>
<td>running</td>
<td>36.44TB</td>
<td>8%</td>
</tr>
</tbody>
</table>
```

The following example displays information about all operations on the gold storage service on the Infinite Volume named repo_vol on the Vserver named vs1:

```
cmd> autobalance volume show rebalance -vserver vs1 -volume repo_vol -storage-service gold

<table>
<thead>
<tr>
<th>Vserver</th>
<th>Volume</th>
<th>Storage Service</th>
<th>State</th>
<th>Target</th>
<th>Percent Transferred</th>
</tr>
</thead>
<tbody>
<tr>
<td>vs1</td>
<td>repo_managed gold</td>
<td>running</td>
<td>17.22TB</td>
<td>18%</td>
<td></td>
</tr>
<tr>
<td>vs1</td>
<td>repo_managed silver</td>
<td>complete</td>
<td>19.25TB</td>
<td>100%</td>
<td></td>
</tr>
</tbody>
</table>
```
**autobalance volume rebalance start**

Start Auto Balance Volume for an Infinite Volume

**Availability:** This command is available to cluster and Vserver administrators at the advanced privilege level.

**Description**
The `autobalance volume rebalance start` command allows the user to start Auto Balance Volume and rebalance the used data capacity in an Infinite Volume after files are created. Auto Balance Volume moves data between data constituents of an Infinite Volume. If the Infinite Volume uses storage services, Auto Balance Volume moves data between data constituents of a storage service in an Infinite Volume. Auto Balance Volume ensures that all data constituents in an Infinite Volume or all data constituents in a storage service of an Infinite Volume have similar amounts of used data capacity. The `autobalance volume rebalance start` command is only supported for Infinite Volumes.

**Parameters**

- `vserver <vserver name>` - Vserver
  This specifies the Vserver on which the Infinite Volume to be rebalanced is located.

- `volume <volume name>` - Volume Name
  This specifies the Infinite Volume to be rebalanced.

- `storage-service <storage service name>` - Storage Service
  If the Infinite Volume uses storage services, the `storage-service` parameter is required to specify the storage service to be rebalanced. If the Infinite Volume does not use storage services, the `storage-service` parameter cannot be specified, and the entire Infinite Volume will be rebalanced.

- `timeout <integer>` - Requisition Timeout (seconds)
  The maximum number of seconds Auto Balance Volume will permit an operation to continue without moving files, before moving the operation to the complete state.

**Examples**
The following example starts rebalancing used capacity in the gold storage service for an Infinite Volume named vol:

```
cluster1:*> autobalance volume rebalance start
     -vserver vs0 -volume vol -storage-service gold
```

The following example starts rebalancing used capacity in an Infinite Volume named vol:

```
cluster1:*> autobalance volume rebalance start
     -vserver vs1 -volume vol
```

**autobalance volume rebalance stop**

Stop Auto Balance Volume for an Infinite Volume

**Availability:** This command is available to cluster and Vserver administrators at the advanced privilege level.

**Description**
The `autobalance volume rebalance stop` command allows the user to stop Auto Balance Volume. The `autobalance volume rebalance stop` command is only supported for Infinite Volumes.

**Parameters**

- `vserver <vserver name>` - Vserver
  This specifies the Vserver on which the Infinite Volume being rebalanced is located.
-volume <volume name> - Volume Name
This specifies the Infinite Volume being rebalanced.

-storage-service <storage service name> - Storage Service
If the Infinite Volume being rebalanced uses storage services, the storage-service parameter is required to specify the storage service being rebalanced. If the Infinite Volume being rebalanced does not use storage services, the storage-service parameter cannot be specified because the entire Infinite Volume is being rebalanced.

Examples
The following example stops rebalancing used capacity for the gold storage service for an Infinite Volume named vol:

```
cluster1::*> autobalance volume rebalance stop
    -vserver vs0 -volume vol -storage-service gold
```

The following example stops rebalancing used capacity for an Infinite Volume named vol:

```
cluster1::*> autobalance volume rebalance stop
    -vserver vs1 -volume vol
```

autobalance aggregate commands
Auto Balance Aggregate

autobalance aggregate show-aggregate-state
Display the Auto Balance Aggregate state for an aggregate

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
The autobalance aggregate show-aggregate-state command displays information about an aggregate state that is considered by the Auto Balance Aggregate feature.

Parameters

{ [-fields <fieldname>,...] | [-instance ]]  
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

| [-instance ] |
If you specify the -instance parameter, the command displays detailed information about all fields.

[-node {<nodename> | local}] - Node Name  
If this parameter is specified, the display will be limited to only those aggregates with a node that matches the specified value.

[-aggregate <aggregate name>] - Name of the Aggregate  
If this parameter is specified, the display will be limited to only that aggregate with a name that matches the specified value.

[-total-size {<integer> [KB | MB | GB | TB | PB]}) - Total Size of the Aggregate  
If this parameter is specified, the display will be limited to only those aggregates with a total-size that matches the specified value.
[-used-size \{<integer> [KB|MB|GB|TB|PB]\}] - Used Size of the Aggregate
   If this parameter is specified, the display will be limited to only those aggregates with a used-size that matches
   the specified value.

[-aggregate-unbalanced-threshold \{<integer> [KB|MB|GB|TB|PB]\}] - Threshold When Aggregate Is
   Considered Unbalanced
   If this parameter is specified, the display will be limited to only those aggregates with a threshold that matches
   the specified value.

[-outgoing-size \{<integer> [KB|MB|GB|TB|PB]\}] - Size of Outgoing Volumes in the Aggregate
   If this parameter is specified, the display will be limited to only those aggregates with an outgoing-size that
   matches the specified value. Outgoing size will be equal to the total size of the volumes that move away from
   each one of those aggregate.

[-incoming-size \{<integer> [KB|MB|GB|TB|PB]\}] - Size of Incoming Volumes in the Aggregate
   If this parameter is specified, the display will be limited to only those aggregates with an incoming-size that
   matches the specified value. Incoming size will be equal to the total size of the volumes that move towards to
   each one of those aggregates.

[-raidtype \{raid_tec|raid_dp|raid4\}] - RAID Type
   If this parameter is specified, the display will be limited to only those aggregates with a raidtype that matches
   the specified value.

[-home-cluster <UUID>] - Home Cluster ID
   If this parameter is specified, the display will be limited to only those aggregates with a home-cluster ID that
   matches the specified value.

[-is-hybrid \{true|false\}] - Aggregate Is a Hybrid
   If this parameter is specified as true, the display will be limited to only hybrid aggregates. If the parameter is
   specified as false, the display will be limited to only non-hybrid aggregates.

[-is-incoming-volume-thin \{true|false\}] - An Incoming Volume Is Thin
   When you use thin provisioning for a volume, it can run out of space even if it has not yet consumed its
   nominal size and you should carefully monitor space utilization to avoid unexpected errors due to the volume
   running out of space. If this parameter is specified as true, the display will be limited to only those aggregates
   which are the target of a move of thin volume. If the parameter is specified as false, the display will be limited
to only those aggregates which are not the target of a move of thin volume.

[-is-balanceable \{true|false\}] - Is Balanceable
   If this parameter is specified as true, the display will be limited to only balanceable aggregates. If the parameter
   is specified as false, the display will be limited to only non-balanceable aggregates.

[-is-move-target \{true|false\}] - Aggregate Is a Volume Move Target
   If this parameter is specified as true, the display will be limited to only those aggregates which are target of a
   volume move. If the parameter is specified as false, the display will be limited to only those aggregates which
   are not the target of a volume move.

[-attributes <text>, ...] - Aggregate Attributes
   If this parameter is specified, the display will be limited to only those aggregates with attributes that matches
   the specified values.

[-aggregate-available-threshold \{<integer> [KB|MB|GB|TB|PB]\}] - Threshold When Aggregate Is
   Considered Balanced
   If this parameter is specified, the display will be limited to only those aggregates which meet the specified
   threshold to be considered as balanced.

Examples
   The following example displays information about the state for all aggregates in the cluster.
The following example displays information about all entries of the aggregate state, for all aggregates in the cluster.

```
cluster1::*> autobalance aggregate show-aggregate-state -instance
    Node Name: cluster-1-01
    Name of the Aggregate: aggr0
    Total Size of the Aggregate: 4.78GB
    Used Size of the Aggregate: 4.56GB
    Threshold When Aggregate Is Considered Unbalanced: 3.34GB
    Size of Outgoing Volumes in the Aggregate: 0B
    Size of Incoming Volumes in the Aggregate: 0B
    RAID Type: raid_dp
    Home Cluster ID: edf0379b-16da-11e6-aa3c-0050568558c2
    Attributes: CFO
    Excluded
    Mroot
    Aggregate Used Space Threshold: 3.34GB
    Aggregate Available Space Threshold: 1.91GB
    RAID Type: raid_dp
    Home Cluster ID: edf0379b-16da-11e6-aa3c-0050568558c2
    Attributes: CFO
    Excluded
    Mroot

    Aggregate: aggr_1
    Total Size: 12.61GB
    Used Size: 111.6MB
    Threshold When Aggregate Is Considered Unbalanced: 8.83GB
    Size of Outgoing Volumes in the Aggregate: 0B
    Size of Incoming Volumes in the Aggregate: 0B
    RAID Type: raid4
    Home Cluster ID: edf0379b-16da-11e6-aa3c-0050568558c2
    Attributes: Excluded
    Mroot
    Threshold When Aggregate Is Considered Balanced: 5.04GB

    Node Name: cluster-1-01
    Name of the Aggregate: aggr_1
    Total Size of the Aggregate: 12.61GB
    Used Size of the Aggregate: 111.6MB
    Threshold When Aggregate Is Considered Unbalanced: 8.83GB
    Size of Outgoing Volumes in the Aggregate: 0B
    Size of Incoming Volumes in the Aggregate: 0B
    RAID Type: raid4
    Home Cluster ID: edf0379b-16da-11e6-aa3c-0050568558c2
    Attributes: Excluded
    Mroot
    Threshold When Aggregate Is Considered Balanced: 5.04GB
```

autobalance aggregate show-unbalanced-volume-state

Display the Auto Balance Aggregate state for a volume

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.
Description
The autobalance aggregate show-unbalanced-volume-state command displays information about a volume that is considered by the Auto Balance Aggregate feature.

Parameters

[-fields <fieldname>, ...]
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

[-instance]
If you specify the -instance parameter, the command displays detailed information about all fields.

[-node <nodename> | local] - Node Name
If this parameter is specified, the display will be limited to only those volumes with a node that matches the specified value.

[-DSID <integer>] - DSID of the Last Volume Queried
If this parameter is specified, the display will be limited to only those volumes with a DSID that matches the specified value.

[-aggregate <aggregate name>] - Aggregate
If this parameter is specified, the display will be limited to only those volumes with an aggregate name that matches the specified value.

[-volume-name <text>] - Name of the Volume
If this parameter is specified, the display will be limited to only that volume with a name that matches the specified value.

[-last-threshold-crossed-time <MM/DD/YYYY HH:MM:SS>] - Last Time Threshold Crossed
If this parameter is specified, the display will be limited to only those volumes with a threshold crossing time that matches the specified value.

[-last-placed-time <MM/DD/YYYY HH:MM:SS>] - Last Time Volume Was Moved
If this parameter is specified, the display will be limited to only those volumes with a last time they have been moved that matches the specified value.

[-is-moving {true|false}] - Is Volume Currently Moving
If this parameter is specified as true, the display will be limited to only the moving volumes. If the parameter is specified as false, the display will be limited to only the non-moving volumes.

[-is-quiesced {true|false}] - Is Volume Quiesced
If this parameter is specified as true, the display will be limited to only the quiesced volumes. If the parameter is specified as false, the display will be limited to only the non-quiesced volumes.

[-total-footprint <integer> [KB|MB|GB|TB|PB]] - Total Size of the Volume
If this parameter is specified, the display will be limited to only those volumes with a total footprint that matches the specified value.

[-attributes <text>, ...] - Volume's Attributes
If this parameter is specified, the display will be limited to only those volumes with attributes that matches the specified value.

[-last-checked <MM/DD/YYYY HH:MM:SS>] - Last Time Volume State Was Checked
If this parameter is specified, the display will be limited to only those volumes with a last time their state was checked that matches the specified value.
Examples

The following example display information about all of the unbalanced volumes that the Auto Balance Aggregate feature is aware of.

```
cluster1::*> autobalance aggregate show-unbalanced-volume-state
    Last Checked On: 3/13/2014 14:32:01
    Volume: ro10
    Footprint: 20.20MB
    Last Time Over IOPS Threshold: 3/12/2014 16:20:18
    Last Placed: 3/11/2014 10:16:04
    Attributes: Over IOPS Threshold
                Stabilizing

    Volume: test
    Footprint: 20.20MB
    Last Time Over IOPS Threshold: 3/12/2014 16:20:18
    Last Placed: 3/11/2014 10:16:42
    Attributes: Over IOPS Threshold
                In Mirror
                Stabilizing
```

The following example displays all of the information that the Auto Balance Aggregate feature has collected for all of the unbalanced volumes it is aware of.

```
cluster1::*> autobalance aggregate show-unbalanced-volume-state -instance
    Node Name: cluster-1-01
    DSID of the Last Volume Queried: 1025
        Aggregate: aggr_1
        Name of the Volume: ro10
        Last Time Threshold Crossed: 3/12/2014 16:20:18
        Last Time Volume Was Moved: 3/11/2014 10:16:04
        Is Volume Currently Moving: false
        Is Volume Quiesced: false
        Total Size of the Volume: 20.20MB
        Volume's Attributes: Over IOPS Threshold
                             Stabilizing
    Last Time Volume State Was Checked: 3/13/2014 08:20:18

    Node Name: cluster-1-01
    DSID of the Last Volume Queried: 1026
        Aggregate: aggr_1
        Name of the Volume: test
        Last Time Threshold Crossed: 3/12/2014 16:20:18
        Last Time Volume Was Moved: 3/11/2014 10:16:42
        Is Volume Currently Moving: false
        Is Volume Quiesced: false
        Total Size of the Volume: 20.20MB
        Volume's Attributes: Over IOPS Threshold
                             In Mirror
                             Stabilizing
    Last Time Volume State Was Checked: 3/13/2014 08:20:18
```

**autobalance aggregate config commands**

Auto Balance Aggregate configuration

**autobalance aggregate config modify**

Modify the Auto Balance Aggregate feature configuration

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.
Description
The \texttt{autobalance aggregate config modify} command allows the user to customize the parameters that determine when volumes should be considered for automatic move or recommendation by the Auto Balance Aggregate feature.

Parameters

\texttt{-is-enabled \{true|false\}} - Is the Auto Balance Aggregate Feature Enabled

This specifies whether the Auto Balance Aggregate feature is enabled and running.

\texttt{-aggregate-unbalanced-threshold-percent <integer>} - Threshold When Aggregate Is Considered Unbalanced (%)

This specifies the space used threshold percentage that will cause the Auto Balance Aggregate feature to consider an aggregate as unbalanced.

\texttt{-aggregate-available-threshold-percent <integer>} - Threshold When Aggregate Is Considered Balanced (%)

This specifies the threshold percentage which will determine if an aggregate is a target destination for a move. The Auto Balance Aggregate feature will attempt to move volumes from an unbalanced aggregate until it is under this percentage.

Examples
The following example displays a modification for the default configuration of the Auto Balance Aggregate feature.

```
cluster1::*> autobalance aggregate config show
  Is the Auto Balance Aggregate Feature Enabled: false
  Threshold When Aggregate Is Considered Unbalanced (%): 70
  Threshold When Aggregate Is Considered Balanced (%): 40

cluster1::*> autobalance aggregate config modify -is-enabled true

cluster1::*> autobalance aggregate config show
  Is the Auto Balance Aggregate Feature Enabled: true
  Threshold When Aggregate Is Considered Unbalanced (%): 70
  Threshold When Aggregate Is Considered Balanced (%): 40
```

At the diagnostic level, there are additional modifiable parameters.

```
cluster1::*> autobalance aggregate config show
  Is the Auto Balance Aggregate Feature Enabled: false
  Mode of the Auto Balance Aggregate Feature: recommend
  Polling Interval: 3600
  Threshold When Aggregate Is Considered Unbalanced (%): 70
  Threshold When Aggregate Is Considered Balanced (%): 40
  Volume Operations Threshold (IOPs): 100
  Volume Operations Threshold Not Exceeded for Duration: 24
  Volume Not Moved Again for Duration: 48

cluster1::*> autobalance aggregate config modify -mode auto -polling-interval 4000

cluster1::*> autobalance aggregate config show
  Is the Auto Balance Aggregate Feature Enabled: false
  Mode of the Auto Balance Aggregate Feature: auto
  Polling Interval: 4000
  Threshold When Aggregate Is Considered Unbalanced (%): 70
  Threshold When Aggregate Is Considered Balanced (%): 40
  Volume Operations Threshold (IOPs): 100
  Volume Operations Threshold Not Exceeded for Duration: 24
  Volume Not Moved Again for Duration: 48
```
autobalance aggregate config show

Display the Auto Balance Aggregate feature configuration

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
The autobalance aggregate config show command displays information about parameters that determine when volumes should be considered for automatic move or recommendation by the Auto Balance Aggregate feature.

Examples
The following example displays the default configuration for the Auto Balance Aggregate feature

```
cluster1::*> autobalance aggregate config show
  Is the Auto Balance Aggregate Feature Enabled: false
  Threshold When Aggregate Is Considered Unbalanced (%): 70
  Threshold When Aggregate Is Considered Balanced (%): 40
```

At the diagnostic level, the output displays the information below.

```
  Is the Auto Balance Aggregate Feature Enabled: false
  Mode of the Auto Balance Aggregate Feature: recommend
  Polling Interval: 3600
  Threshold When Aggregate Is Considered Unbalanced (%): 70
  Threshold When Aggregate Is Considered Balanced (%): 40
  Volume Operations Threshold (IOPS): 100
  Volume Operations Threshold Not Exceeded for Duration: 24
  Volume Not Moved Again for Duration: 48
```

Cluster Commands

Manage clusters

The cluster commands enable you to create and manage Data ONTAP 8 clusters.

cluster add-node

Expand the cluster by discovering and adding new nodes

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The cluster add-node command discovers and adds new nodes to the cluster. When the -node-count parameter is specified, the command attempts to add that many nodes to the cluster. The -node-ip parameter can be specified to directly add a node.

Parameters

```
{ -node-count <integer> - Number of Nodes Being Added
  
  Number of nodes to be added to the cluster. If fewer nodes are discovered, all the discovered nodes are added to the cluster and the command will fail since there are fewer nodes than specified. If more nodes are found
```

than the number specified, the command will fail because there is no way to determine which nodes you intend to add to the cluster.

Note: The -node-count parameter is supported on non-shared architecture platforms only.

<table>
<thead>
<tr>
<th>-node-ip &lt;IP Address&gt;</th>
<th>Cluster IP Address of Node</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Cluster IP address of the node to add. When this parameter is provided, the command directly adds the node.</td>
</tr>
</tbody>
</table>

Note: The -node-ip parameter is supported on non-shared architecture platforms only.

[-foreground {true|false}] - Foreground Process

When set to false the command runs in the background as a job. The default is true, which causes the command to return after the operation completes.

Examples

The following example adds a node using -node-ip:

```
cluster1::> cluster add-node -node-ip 192.168.1.5
```

The following example adds 3 nodes using -node-count.

```
cluster1::> cluster add-node -node-count 3
```

cluster create

Create a cluster

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The cluster create command creates a cluster with one node. Once you create the cluster, add additional nodes to the cluster by using the cluster join command.

Note that single-node clusters do not require configuring the cluster network. A cluster network interface must be configured before other nodes can join the cluster.

Parameters

<table>
<thead>
<tr>
<th>-license &lt;License Code V2&gt;</th>
<th>Base License</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Use this optional parameter to specify the base license for the cluster. Obtain this value from your sales or support representative.</td>
</tr>
</tbody>
</table>

-iclustername <text> - Cluster Name

Use this parameter to specify the name of the cluster you are creating.

- The name must contain only the following characters: A-Z, a-z, 0-9, "-" or "_".
- The first character must be one of the following characters: A-Z or a-z.
- The last character must be one of the following characters: A-Z, a-z or 0-9.
- The maximum supported length is 44 characters.
• The system reserves the following names: "all", "cluster", "local" and "localhost".

[-node-count <integer>] - Node Count
Use this parameter to specify the number of nodes in the cluster you are creating.

• -node-count parameter is supported on non-shared architecture platforms only.

Examples
The following example creates a cluster named cluster1

    cluster1::> cluster create -license ABCDEFGHIJKLMNOP -clustername cluster1

The following example creates a cluster named cluster1 with node-count 4 on a non-shared architecture platform.

    cluster1::> cluster create -clustername cluster1 -node-count 4

Related references

cluster join on page 18

cluster join
Join an existing cluster using the specified member's IP address or by cluster name

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The cluster join command adds a node to an existing cluster. Use the cluster create command to create a cluster if one does not already exist.

Note that a cluster network interface must be configured for the cluster before other nodes can join the cluster.

Parameters

{ -clusteripaddr <IP Address> - IP Address of a Cluster Interface from a Node in the Cluster
Use this parameter to specify the IP address of a cluster interface. This must be the IP address of a cluster interface of a node that is already in the cluster. This parameter is mutually exclusive with the -clustername parameter.

| -clustername <text> - Cluster Name of the Cluster to Join
Use this parameter to specify the name of an existing cluster to join. This parameter is mutually exclusive with the -clusteripaddr parameter.

Examples
The following example joins the local node to a cluster. The IP address 192.0.2.66 is the address of a cluster interface of a node that already belongs to the cluster.

    node::> cluster join -clusteripaddr 192.0.2.66

This next example joins the local node to a cluster named "cluster1". "cluster1" is a cluster that already exists.

*cluster create* on page 17

---

**cluster modify**

Modify cluster node membership attributes

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

**Description**

The `cluster modify` command modifies the cluster attributes of a node, including its eligibility to participate in the cluster.

At the advanced privilege level, you can use the command to specify whether a node holds epsilon. Epsilon is an extra fractional vote that enables quorum to form using slightly weaker requirements. For example, two out of four eligible nodes are sufficient to form quorum if one of those two nodes holds epsilon.

**Parameters**

- `-node {<nodename>|local}` - Node
  
  Use this parameter to specify the name of the node to modify. If you do not specify a node, the command runs on the local node.

- `[-epsilon {true|false}]` - Epsilon
  
  Use this parameter with the value `true` to specify that the node holds Epsilon in the cluster. Use this parameter with the value `false` to specify that the node does not hold Epsilon in the cluster. In a cluster, only one node can be designated as Epsilon at any given time. You can designate a node as Epsilon to add weight to its voting in a cluster with an even number of nodes.

- `[-eligibility {true|false}]` - Eligibility
  
  Use this parameter with the value `true` to specify that the node is eligible to participate in the cluster. Use this parameter with the value `false` to specify that the node is not eligible to participate in the cluster.

  If you modify a node as ineligible to participate in the cluster, the command prompts you for confirmation before it runs.

- `[-skip-quorum-check-before-ineligible {true}]` - Skip Quorum Check Before Setting Node Ineligible
  
  If this parameter is specified, quorum checks will be skipped prior to setting a node ineligible. When setting a node to ineligible, the operation will continue even if there is a possible data outage due to a quorum issue.

---

**Examples**

This example modifies a node to make it eligible to participate in the cluster.

```
cluster1::*> cluster modify -node node3 -eligibility true
```

The following example removes epsilon from the node named node0 and adds it to the node named node1:

```
cluster1::*> cluster modify -node node0 -epsilon false
cluster1::*> cluster modify -node node1 -epsilon true
```
**cluster ping-cluster**

Ping remote cluster interfaces and perform RPC server check

**Availability:** This command is available to cluster administrators at the advanced privilege level.

**Description**
The `cluster ping-cluster` command probes network connectivity to remote cluster interfaces, and performs an RPC server check.

**Parameters**
- `-node <nodename>` - Node
  
  Use this parameter to send the ping from the node you specify.

  `[--use-sitelist {true|false}]` - Use Sitelist for Cluster Interfaces
  
  Use this parameter with the value `true` to specify that the command use the sitelist to determine any incomplete cluster IP information. Use this parameter with the value `false` to specify that the command not use the sitelist.

  `[--skip-rpccheck {true|false}]` - Skip RPC Server Check
  
  Use this parameter with the value `true` to specify that the command not perform the rpcinfo check of remote hosts. Use this parameter with the value `false` to specify that the command perform the rpcinfo check. The rpcinfo check checks the status of the RPC servers on the remote hosts. By default, the rpcinfo check runs on the program number of the portmapper. Use the `--rpc-prognum <integer>` parameter to override this default.

  `[--rpc-prognum <integer>]` - RPC Server to Check
  
  Use this parameter to override default behavior and run the rpcinfo check on the program number you specify. By default, the rpcinfo check runs on the program number of the portmapper.

**Examples**
The following example shows typical output for this command.

```
cluster1::*> cluster ping-cluster --node node1
Host is node1
Getting addresses from network interface table...
Local = 10.254.231.102  10.254.91.42
Remote = 10.254.42.25    10.254.16.228
Ping status:
....
Basic connectivity succeeds on 4 path(s)
Basic connectivity fails on 0 path(s)
................
Detected 1500 byte MTU on 4 path(s):
  Local 10.254.231.102 to Remote 10.254.16.228
  Local 10.254.231.102 to Remote 10.254.42.25
Local 10.254.91.42 to Remote 10.254.16.228
Local 10.254.91.42 to Remote 10.254.42.25
Larger than PMTU communication succeeds on 4 path(s)
RPC status:
  2 paths up, 0 paths down (tcp check)
  2 paths up, 0 paths down (udp check)
```
Description
The cluster setup command runs the cluster setup wizard, which can be used to either create a cluster or join a node to an existing cluster. When you run the cluster setup wizard, enter the appropriate information at the prompts. You will be asked to provide the following information to create a cluster:

- Cluster name
- Cluster base license key
- Feature license keys
- Cluster administrator's password
- Cluster management interface port, IP address, netmask, default gateway
- Node management interface port, IP address, netmask, default gateway
- DNS domain names
- Name server IP addresses
- Location

You will be asked to provide the following information to join a cluster:

- Cluster name
- Node management interface port, IP address, netmask, default gateway

The cluster management interface is used for managing the cluster. It provides one IP address to manage the cluster and will fail over to another node, if necessary. This is the preferred IP address for managing the cluster, but you can also manage the cluster by logging in to the node management IP address of a node in the cluster. Since the cluster management interface must be able to fail over, the port role for the interface must be "data" and typically the best choice for an IP address is one on the data network. The node management interface will not fail over, so an IP address on the management network and a port with the role "node management" is the best choice. Alternatively, you can assign an IP address on the data network to the cluster management interface - if that is better in your network topology - but the port must be a data port. The two examples below illustrate the cluster create and cluster join operations, respectively.

Examples
The following example shows the create option of cluster setup.

```
node::> cluster setup
Welcome to the cluster setup wizard.
You can enter the following commands at any time:
"help" or "?" - if you want to have a question clarified,
"back" - if you want to change previously answered questions, and
"exit" or "quit" - if you want to quit the cluster setup wizard.
Any changes you made before quitting will be saved.
You can return to cluster setup at any time by typing "cluster setup".
To accept a default or omit a question, do not enter a value.

Do you want to create a new cluster or join an existing cluster? {create, join}: create
Do you intend for this node to be used as a single node cluster? {yes, no} [no]: no
Will the cluster network be configured to use network switches? {yes}:
yes
System Defaults:
Private cluster network ports [e0a,e0b].
Cluster port MTU values will be set to 9000.
```

21
Cluster interface IP addresses will be automatically generated.
Do you want to use these defaults? [yes, no] [yes]:
It can take several minutes to create cluster interfaces...

Step 1 of 5: Create a Cluster
You can type "back", "exit", or "help" at any question.
Enter the cluster name: cluster1
Enter the cluster base license key: ABCDEFGHIJKLMNOP
Creating cluster cluster1
Starting cluster support services ..... 
Cluster cluster1 has been created.

Step 2 of 5: Add Feature License Keys
You can type "back", "exit", or "help" at any question.
Enter an additional license key []:

Step 3 of 5: Set Up a Vserver for Cluster Administration
You can type "back", "exit", or "help" at any question.
Enter the cluster administrator's (username "admin") password:
Retype the password:
Enter the cluster management interface port [e0c]:
Enter the cluster management interface IP address: 192.0.2.60
Enter the cluster management interface netmask: 255.255.255.192
Enter the cluster management interface default gateway: 192.0.2.1
A cluster management interface on port e0c with IP address 192.0.2.60 has been created. You can use this address to connect to and manage the cluster.
Enter the DNS domain names: data.example.com
Enter the name server IP addresses: 192.0.2.147
DNS lookup for the admin Vserver will use the data.example.com domain.

Step 4 of 5: Configure Storage Failover (SFO)
You can type "back", "exit", or "help" at any question.
SFO is licensed.
SFO will be enabled when the partner joins the cluster.

Step 5 of 5: Set Up the Node
You can type "back", "exit", or "help" at any question.
Where is the controller located []: Sunnyvale
Enter the node management interface port [e0c]: e0d
Enter the node management interface IP address: 192.0.2.66
Enter the node management interface netmask: 255.255.255.192
Enter the node management interface default gateway: 192.0.2.1
A node management interface on port e0d with IP address 192.0.2.66 has been created.
Cluster "cluster1" has been created.

To complete cluster setup, you must join each additional node to the cluster by running "cluster setup" on each node.

To complete system configuration, you can use either OnCommand System Manager or the Data ONTAP command-line interface.

To access OnCommand System Manager, point your web browser to the cluster management IP address (https://192.0.2.60).
To access the command-line interface, connect to the cluster management IP address (for example, ssh admin@192.0.2.60).

An example of using `cluster setup` to join a cluster is shown below.

```
node::> cluster setup
Welcome to the cluster setup wizard.
You can enter the following commands at any time:
"help" or "?" - if you want to have a question clarified,
"back" - if you want to change previously answered questions, and
"exit" or "quit" - if you want to quit the cluster setup wizard.
Any changes you made before quitting will be saved.
You can return to cluster setup at any time by typing "cluster setup".
To accept a default or omit a question, do not enter a value.

Do you want to create a new cluster or join an existing cluster? {create, join}: join

System Defaults:
Private cluster network ports [e0a,e0b].
Cluster port MTU values will be set to 9000.
Cluster interface IP addresses will be automatically generated.

Do you want to use these defaults? {yes, no} [yes]:

It can take several minutes to create cluster interfaces...

Step 1 of 3: Join an Existing Cluster
You can type "back", "exit", or "help" at any question.

Enter the name of the cluster you would like to join [cluster1]:
Joining cluster cluster1

Step 2 of 3: Configure Storage Failover (SFO)
You can type "back", "exit", or "help" at any question.
SFO is licensed.
SFO will be enabled when the partner joins the cluster.

Step 3 of 3: Set Up the Node
You can type "back", "exit", or "help" at any question.

Enter the node management interface port [e0c]:
Enter the node management interface IP address: 192.0.2.67
Enter the node management interface netmask [255.255.255.192]:
Enter the node management interface default gateway [192.0.2.1]:
A node management interface on port e0c with IP address 192.0.2.67 has been created.

This node has been joined to cluster "cluster1".

To complete cluster setup, you must join each additional node to the cluster by running "cluster setup" on each node.

To complete system configuration, you can use either OnCommand System Manager or the Data ONTAP command-line interface.

To access OnCommand System Manager, point your web browser to the cluster management IP address (https://192.0.2.60).
To access the command-line interface, connect to the cluster management IP address (for example, ssh admin@192.0.2.60).

**cluster show**

Display cluster node members

**Availability:** This command is available to cluster administrators at the `admin` privilege level.

**Description**

The `cluster show` command displays information about the nodes in a cluster.

**Parameters**

```
[-fields <fieldname>, ...]
```

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

```
[-instance]
```

If you specify the `-instance` parameter, the command displays detailed information about all fields.

```
[-node {<nodename> | local}] - Node
```

Selects the nodes that match this parameter value.

```
[-node-uuid <UUID>] - UUID (privilege: advanced)
```

Selects the nodes that match this parameter value.

```
[-epsilon {true | false}] - Epsilon (privilege: advanced)
```

Selects the nodes that match this parameter value. In a cluster, only one node can be designated as Epsilon at any given time. You can designate a node as Epsilon to add weight to its voting in a cluster with an even number of nodes.

```
[-eligibility {true | false}] - Eligibility
```

Selects the nodes that match this parameter value (true means eligible to participate in the cluster).

```
[-health {true | false}] - Health
```

Selects the nodes that match this parameter value (true means online).

**Examples**

The following example displays information about all nodes in the cluster:

```text
cluster1::> cluster show
Node                  Health  Eligibility
--------------------- ------- ------------
node0                 true    true
node1                 true    true
node2                 true    true
node3                 true    true
```

The following example displays information about the node named node1:
cluster unjoin

Unjoin or remove a node from the cluster

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
The cluster unjoin command removes a node from a cluster.

Before you can remove a node from a cluster, you must shut down all of the node's shared resources, such as virtual interfaces to clients. If any of a node's shared resources are still active, the command fails. The failure message will display which active resources must be shut down before the node can be removed from the cluster.

Parameters
-node <nodename> - Node to unjoin
  Use this parameter to specify the name of the node to remove from the cluster.

[-skip-quorum-check-before-unjoin [true]] - Skip Quorum Check Before Unjoin
  If this parameter is specified, quorum checks will be skipped prior to the unjoin. The operation will continue even if there is a possible data outage due to a quorum issue.

Examples
The following example shows how to remove the node named node4 from the cluster.

```
cluster1::*> cluster unjoin -node node4
```

The following example forcibly unjoins the node from the cluster:

```
cluster1::*> cluster unjoin -node node4 -force
```

cluster contact-info commands

Manage contact information for the cluster.

cluster contact-info modify

Modify contact information for the cluster

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The cluster contact-info modify command modifies contact information for the cluster administrators. If any values contain spaces, you must enclose those values in quotes.

Use the cluster contact-info show command to display contact information for the cluster administrators.
Parameters

[-primary-name <text>] - Name of Primary Contact
Use this parameter to specify the name of the primary contact.

[-primary-phone <text>] - Phone Number of Primary Contact
Use this parameter to specify the phone number of the primary contact.

[-primary-alt-phone <text>] - Alternate Phone Number of Primary Contact
Use this parameter to specify the alternate phone number of the primary contact.

[-primary-email <text>] - Email Address or User ID of Primary Contact
Use this parameter to specify the email address of the primary contact.

[-secondary-name <text>] - Name of Secondary Contact
Use this parameter to specify the name of the secondary contact.

[-secondary-phone <text>] - Phone Number of Secondary Contact
Use this parameter to specify the phone number of the secondary contact.

[-secondary-alt-phone <text>] - Alternate Phone Number of Secondary Contact
Use this parameter to specify the alternate phone number of the secondary contact.

[-secondary-email <text>] - Email Address or User ID of Secondary Contact
Use this parameter to specify the email address of the secondary contact.

[-business-name <text>] - Business Name
Use this parameter to specify the name of the business responsible for this cluster.

[-address <text>] - Business Address
Use this parameter to specify the street address of the business responsible for this cluster.

[-city <text>] - City Where Business Resides
Use this parameter to specify the name of the city in which the business is located.

[-state <text>] - State Where Business Resides
Use this parameter to specify the name of the state or province in which the business is located.

Use this parameter to specify the 2-character country code of the country in which the business is located.

[-zip-code <text>] - Postal Code Where Business Resides
Use this parameter to specify the postal or ZIP code area in which the business is located.

Examples

The following example changes the name and phone numbers of the secondary contact person for the cluster.

    cluster1::> cluster contact-info modify -secondary-name "John Doe" -secondary-phone 123.555.0156 -secondary-alt-phone 123.555.0178

The following example changes the mailing address of the business responsible for the cluster.

    cluster1::> cluster contact-info modify -address "123 Example Avenue" -city Exampleville -state "New Example" -zip-code 99999 -country US

Related references

   * cluster contact-info show on page 27
**cluster contact-info show**

Display contact information for the cluster

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**
The `cluster contact-info show` command displays contact information for the cluster administrators.

**Examples**
The following example shows example output for this command.

```
cluster1::> cluster contact-info show
Name of Primary Contact : Richard Roe
Phone Number of Primary Contact : 123.555.0123
Alternate Phone Number of Primary Contact : 123.555.0145
Email Address or User Id of Primary Contact : roe@example.com
Name of Secondary Contact : John Doe
Phone Number of Secondary Contact : 123.555.0167
Alternate Phone Number of Secondary Contact : 123.555.0189
Email Address or User Id of Secondary Contact : doe@example.com
Business Name : Example Dot Com
Business Address : 123 Example Avenue

State Where Business Resides : New Example
2-Character Country Code : US
Postal Code Where Business Resides : 99999
```

**cluster ha commands**

Manage high-availability configuration

**cluster ha modify**

Modify high-availability configuration of cluster management services

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**
The `cluster ha modify` command enables or disables cluster high availability in a two-node cluster. Enable high availability when performing some procedures, such as replacing hardware.

**Note:** This command is required to enable high availability if the cluster only has two nodes. Do not run this command in a cluster that has three or more nodes.

**Note:** Cluster high availability for two-node clusters differs from the storage failover technology used between two nodes for storage high availability.

**Parameters**
- `-configured {true|false}] - HA Configured`
  
  Use this parameter with the value `true` to enable high availability mode in the cluster. Use this parameter with the value `false` to disable high availability mode in the cluster.

**Examples**
The following example enables cluster high availability in a cluster.
cluster ha modify

Show high-availability configuration status for the cluster

**Availability**: This command is available to *cluster* administrators at the *admin* privilege level.

**Description**
The `cluster ha modify` command modifies the high-availability configuration of the cluster.

```
cluster1::> cluster ha modify -configured true
```

---

cluster ha show

Show high-availability configuration status for the cluster

**Availability**: This command is available to *cluster* administrators at the *admin* privilege level.

**Description**
The `cluster ha show` command displays the high-availability status of the cluster. Cluster high-availability mode applies only to two-node clusters.

```
cluster1::> cluster ha show
High Availability Configured: true
```

---

cluster date commands

Manage cluster's date and time setting

cluster date modify

Modify the current date and time for the nodes in the cluster

**Availability**: This command is available to *cluster* administrators at the *admin* privilege level.

**Description**
The `cluster date modify` command sets the time zone, date, and time on every node in the cluster.

**Parameters**

- `-timezone <Area/Location Timezone>` - Time Zone
  This parameter sets the timezone, specified in the Olson format.

- `[-date {MM/DD/YYYY HH:MM:SS [+|-]hh:mm}]` - Date and Time
  This parameter sets the date and time, in the format MM/DD/YYYY HH:MM:SS.

- `[-dateandtime <[YYY][MM]dd[hh][mm][.ss]>]` - Date and Time
  This parameter sets the date and time information, in the format [YYYY][MM]dd[hh][mm][.ss]. The argument for setting the date and time is interpreted as follows:
  - cc First 2 digits of the year (e.g., 20 for 2011).
  - yy Last 2 digits of year (e.g., 10 for 2010).
  - mm Numeric month, a number from 01 to 12.
  - dd Day, a number from 01 to 31.
  - hh Hour, a number from 00 to 23.
  - mm Minute, a number from 00 to 59.
• ss Second, a number from 00 to 59.

If the first two digits of the year are omitted, and the last two digits are greater than 68, a date in the 1900s is used. Otherwise, a date in the 2000s is used. If all four digits of the year are omitted, the default is the current year. If the month or day is omitted, the default is the current month or day, respectively. If the seconds are omitted, the default is set to 00. The system automatically handles the time changes for Daylight Saving and Standard time, and for leap seconds and years.

This parameter sets the date and time information in Coordinated Universal Time (UTC), in the format [[[[cc]yy]mm]dd]hhmm[.ss]]. -u is an alias for -utcdateandtime. The argument for setting the date and time is interpreted as follows:

• cc First 2 digits of the year (e.g., 20 for 2011).
• yy Last 2 digits of year (e.g., 10 for 2010).
• mm Numeric month, a number from 01 to 12.
• dd Day, a number from 01 to 31.
• hh Hour, a number from 00 to 23.
• mm Minute, a number from 00 to 59.
• ss Second, a number from 00 to 59.

If the first two digits of the year are omitted, and the last two digits are greater than 68, a date in the 1900s is used. Otherwise, a date in the 2000s is used. If all four digits of the year are omitted, the default is the current year. If the month or day is omitted, the default is the current month or day, respectively. If the seconds are omitted, the default is set to 00. Time changes for Daylight Saving and Standard time, and for leap seconds and years, are handled automatically.

Examples

The following example sets the date and time to January 1 2011, at 1:00 a.m.:

```
cluster1::> cluster date modify -date "01/01/2011 01:00:00"
```

The following example sets the date and time in the UTC format to May 22, 2011, at 09:25:00 a.m.:

```
cluster1::> cluster date modify -u 201105220925.00.
```

cluster date show

Display the current date and time for the nodes in the cluster

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The cluster date show command displays the time zone, date, and time settings for one or more nodes in the cluster. By default, the command displays date and time settings for all nodes in the cluster.

Parameters

{ [-fields <fieldname>, ...] }

If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use ‘-fields?’ to display the fields to specify.
Displays date and time information in Coordinated Universal Time (UTC).

Displays date and time information in UTC.

If you specify the -instance parameter, the command displays detailed information about all fields.

Selects the nodes that match this parameter value.

Selects the nodes that match this parameter value (specified in the Olson format).

Selects the nodes that match this parameter value.

Selects the nodes that match this parameter value.

Selects the nodes that match this parameter value (interpreted as follows):

- cc First 2 digits of the year (e.g., 20 for 2011).
- yy Last 2 digits of year (e.g., 11 for 2011).
- mm Numeric month, a number from 01 to 12.
- dd Day, a number from 01 to 31.
- hh Hour, a number from 00 to 23.
- mm Minute, a number from 00 to 59.
- ss Second, a number from 00 to 59.

-utcmdateandtime | -u <[[cc]yy]mm]dd]hhmm[.ss]> - UTC Date and Time

-u is used as an alias for -utcmdateandtime. Selects the nodes that match this parameter value (interpreted as follows):

- cc First 2 digits of the year (e.g., 20 for 2011).
- yy Last 2 digits of year (e.g., 11 for 2011).
- mm Numeric month, a number from 01 to 12.
- dd Day, a number from 01 to 31.
- hh Hour, a number from 00 to 23.
- mm Minute, a number from 00 to 59.
- ss Second, a number from 00 to 59.

Examples

The following example displays the date and time settings for all nodes in the cluster:

```
cluster1::> cluster date show
Node      Date                Timezone
--------- ------------------- -----------------
node0     10/06/2011 09:35:15 America/New_York
```
cluster image commands

Manage cluster images for automated nondisruptive update

cluster image cancel-update

Cancel an update

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The cluster image cancel-update command is used to cancel an update that is in either paused-by-user or paused-by-error state. The update cannot be canceled if it is not in a paused state.

Examples
The following example displays a cancel-update operation:

```
cluster1:>> cluster image cancel-update
Warning: The cancel operation can result in a mixed version cluster and/or mixed version HA pair. The cancel operation can take several minutes to complete.
Do you want to proceed with the cancel operation? [y|n]: y
Info: Canceling update. It may take a few minutes to finish canceling the update
```

cluster image pause-update

Pause an update

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The cluster image pause-update command is used to pause a currently running update. The update pauses at the next predefined pause point (for example, after validation, download to the boot device, takeover completion, or giveback completion) which might take some time to reach. When the update reaches the pause point, it transitions into the pause-by-user state.

Examples
The following example displays pause-update operation:

```
cluster1:>> cluster image pause-update
Info: Pausing update. It may take a few minutes to finish pausing the update
```
cluster image resume-update

Resume an update

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The cluster image resume-update command is used to resume an update that is currently paused in paused-by-user or paused-by-error state. If the update is not paused then an error is returned.

Parameters
- `-ignore-post-update-checks-failures {true|false}]` - Ignore Post-update-checks Phase Failures
  (privilege: advanced)
  Specifies whether the post update checks phase warnings and/or errors should be ignored. The default value is false.

Examples
The following example shows an resume-update operation:

```
cluster1::> cluster image resume-update
Info: Resuming update...
```

cluster image show

Display currently running image information

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The cluster image show command displays information about the version of Data ONTAP that is running on each node and the date/time when it was installed. By default, the command displays the following information:

- Node name
- Current version
- Installation date and time

Parameters
- `[-fields <fieldname>,...]
  If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

[-instance]
  If you specify the -instance parameter, the command displays detailed information about all fields.

[-node <nodename>|local] - Node
  Displays information about the specified node.

[-version <text>] - Current Version
  Displays information about the nodes running the specified version.

[-date <MM/DD/YYYY HH:MM:SS>] - Date Installed
  Displays information about the nodes with the specified installation date.
Examples
The following example displays information about currently running images on all nodes of the cluster:

```
cluster1::> cluster image show

Current                       Installation
Node     Version                       Date
----------------     -----------------------       ------------
node1     8.3                           -
node2     8.3                           -
2 entries were displayed.
```

**cluster image show-update-history**

Display the update history

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**
The `cluster image show-update-history` command displays the update history for each node. By default, the command displays the following information:

- Status
- Package version
- Start time
- Completion time
- Component ID
- Previous version
- Updated version

**Parameters**

`[-fields <fieldname>, ...]`

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

`[-instance]`

If you specify the `-instance` parameter, the command displays detailed information about all fields.

`[-component-id <text>]` - Component ID

Displays updates for the specified component.

`[-start-time <MM/DD/YYYY HH:MM:SS>]` - Start Time

Displays updates with the specified start time.

`[-package-version <text>]` - Package Version

Displays updates for the specified package version.

`[-status {successful|canceled|back-out}]` - Status

Displays updates that completed with the specified status.

`[-completion-time <MM/DD/YYYY HH:MM:SS>]` - Completion Time

Displays updates with the specified completion time.
[-previous-version <text>] - Previous Version
Displays updates with the specified previous version.

[-updated-version <text>] - Updated Version
Displays updates with the specified updated version.

### Examples

The following example displays history of automated nondisruptive updates:

```bash
cluster1::> cluster image show-update-history
```

### cluster image show-update-log

Display the update transaction log

**Availability:** This command is available to `cluster` administrators at the `advanced` privilege level.

**Description**

The `cluster image show-update-log` command displays detailed information about the currently running, or previously run nondisruptive updates. By default, the command displays the following information:

- Phase
- Transaction
- Transaction ID
- Component ID
- Time stamp
- Status

**Parameters**

```
[-fields <fieldname>, ...]
```

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

```
[-instance]
```

If you specify the `-instance` parameter, the command displays detailed information about all fields.
[-trans-id <integer>] - Transaction ID
Displays information for the step associated with the specified transaction ID.

[-component-id <nodename>|local] - Component ID
Displays information for steps associated with the specified component.

[-phase {validation|prereq-updates|ontap-updates|package-management|default-phase|post-update-checks}] - Transaction Phase
Displays information for steps associated with the specified update phase.

Displays information for steps associated with the specified transaction.

[-timestamp <MM/DD/YYYY HH:MM:SS>] - Timestamp
Displays information for steps associated with the specified timestamp.

[-status {waiting|started|completed|paused-on-error|paused-by-user|pause-pending|cancel-pending|canceled|failed}] - Status
Displays information for steps matching the specified status.

Examples
The following example displays information about automated nondisruptive update events:

cluster image show-update-log-detail

Display detailed information about nondisruptive update events

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
The cluster image show-update-log-detail command displays detailed information about the currently running and previously run nondisruptive update events. By default, the command displays the following information:

- Node
- Transaction ID
- Time stamp
- Destination node
- Task phase
- Task name
- Task status
- Message

Parameters

{{-fields <fieldname>, ...}}
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

{{-instance}}
If you specify the -instance parameter, the command displays detailed information about all fields.

[-node (nodename | local)] - Node
Displays information only for the specified node.

[-task-id <integer>] - Task ID
Displays information only for the specified task ID.

[-posted-time <MM/DD/YYYY HH:MM:SS>] - Posted Time
Displays information that occurred at the specified time.

[-msg-seq-no <integer>] - Message Sequence
Displays information only for the specified message sequence number.

[-current-pid <integer>] - Process ID
Displays information only for the specified process ID.

[-destination <text>] - Task Target node
Displays information only for the specified destination node.

[-ndu-phase {validation | prereq-updates | ontap-updates | package-management | default-phase | post-update-checks}] - Update phase
Displays information only for the specified phase.

Displays information only for the specified task name.

[[-status {created|ready-to-run|running|completed|failed|pause_req|paused|paused-error|cancel_req|canceled|resume_req|default_status}] - Status Of Task

Displays information only for items with the specified status.

[[-message <text>] - Update Log Message

Displays information only for items with the specified message.

[[-msg-type <text>] - Type of Message

Displays information only for items with the specified message type.

[[-src-info <text>] - Source Information

Displays information only for items for the specified source.

Examples

The following example displays detailed information automated nondisruptive updates:

```
cluster1::*> cluster image show-update-log-detail
```

<table>

```
6 entries were displayed.
```

**cluster image show-update-progress**

Display the update progress

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**

The cluster image show-update-progress command displays information about the current state of an update. By default, the command displays the following information:

- Update phase
- Status
- Estimated Duration
• Elapsed Duration

Parameters

    

[-fields <fieldname>, ...]

    If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

[-instance]

    If you specify the -instance parameter, the command displays detailed information about all fields.

[-ndu-phase {validation|prereq-updates|ontap-updates|package-management|default-phase|post-update-checks}] - Update Phase

    Displays information about the specified update phase.

[-phase-status {in-progress|waiting|paused-by-user|paused-on-error|completed|canceled|failed|pause-pending|cancel-pending}] - Phase Status

    Displays information about progress matching the specified phase status.

[-phase-duration <text>] - Phase Duration

    Displays information about progress matching the specified phase duration.

[-phase-comments <text>] - Phase Comments

    Displays information about progress matching the specified phase comments.

[-elapsed-duration <seconds> | [<d> days] <hh>:<mm>[:<ss>]] - Elapsed duration of the phase

    Displays information about progress matching the specified elapsed duration.

[-estimated-duration <seconds> | [<d> days] <hh>:<mm>[:<ss>]] - Estimated duration of the phase

    Displays information about progress matching the specified estimated duration.

[-phase-description <text>] - Phase Description

    Displays information about progress matching the specified phase description.

[-subsystem-name <text>] - Subsystem Name

    Displays information about progress matching the specified subsystem name.

[-subsystem-status <text>] - Subsystem Status

    Displays information about progress matching the specified subsystem status.

[-subsystem-details <text>] - Subsystem Details

    Displays information about progress matching the specified subsystem details.

[-subsystem-action <text>] - Subsystem Action

    Displays information about progress matching the specified subsystem action.

Examples

The following example shows the automated nondisruptive update of two nodes, nodeA and nodeB. In this case, nodeA's update is waiting, nodeB's update is in progress. nodeB's giveback operation is in progress.

```
cluster1::> cluster image show-update-progress

Update Phase Status Estimated Duration Elapsed Duration
----------------- ------------- --------------- ---------------
Pre-update checks completed 00:10:00 00:00:02
Data ONTAP updates in-progress 01:23:00 00:32:07

Details:

Node name Status Status Description
----------------- --------------- ---------------
```
The following example shows the automated nondisruptive update of two nodes, nodeA and nodeB. In this case, automated nondisruptive update is paused-on-error in "Data ONTAP updates" phase. nodeA's update is waiting, nodeB's update is failed. "Status Description" show nodeB's error and action.

<table>

</tbody>
</table>

3 entries were displayed.

Updated nodes: nodeA, nodeB.

cluster1:

cluster image update

Manages an update.

Availability: This command is available to cluster administrators at the admin privilege level.

Description:
The `cluster image update` command is used to initiate a Data ONTAP update. The update is preceded by a validation of the cluster to ensure that any issues that might affect the update are identified. There are two types of updates of a cluster. A rolling update updates Data ONTAP one HA pair at a time. This type of update is performed for clusters with fewer than eight nodes or when the `-force-rolling` option is specified for clusters with eight or more nodes. A batch update is used for clusters of eight or more nodes, and performs updates of multiple HA pairs at the same time.

There are predefined points in the update when the update can be paused (either by the user or by an error). These pause points occur after validation, after download to the boot device, after takeover has completed, and after giveback has completed.

Parameters:
- `-version <text>` - Update Version
  Specifies the Data ONTAP version to use to update the cluster.
- `[nodes <nodename> | local], ...` - Node
  Specifies the nodes that are to be updated.
- `[estimate-only [true]]` - Estimate Only
  Creates a report of the steps that occur during the update without actually doing them.
- `[pause-after {none|all}]` - Update Pause
  Specifies that the update should pause at each predefined pause points (for example, after validation, after download to the boot device, after takeover, and after giveback) during the update.
- `[ignore-validation-warning {true|false}]` - Ignore Validation
  Specifies that the update should proceed even if the validation reports warnings.
- `[skip-confirmation {true|false}]` - Skip Confirmation
  Specifies that a validation that does not detect any error issues should not ask the user to confirm the update but simply proceed with the update.
- `[force-rolling [true]]` - Force Rolling Update
  This option is used for clusters with eight or more nodes to specify that a rolling update (one HA pair at a time) should be done.
- `[stabilize-minutes <integer>]` - Minutes to stabilize
  Specifies the number of minutes that the update should wait after a takeover or giveback is completed. This allows time for the clients to recover from the pause in I/O that occurs during takeover and giveback.
Examples

The following example shows the update operation:

```
cluster1::> cluster image update -version 8.3
```

It can take several minutes to complete validation...

cluster image validate

Validates the cluster's update eligibility

**Availability:** This command is available to cluster administrators at the `admin` privilege level.

**Description**
The `cluster image validate` command checks for issues within the cluster that might lead to problems during the update.

**Parameters**

- `-fields <fieldname>, ...`
  - If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

- `[-version <text>]` - Update Version
  - Specifies the Data ONTAP version to use to validate the cluster.

- `[-rolling [true]]` - Rolling Update
  - Specify this optional parameter on a cluster with eight or more nodes to perform a rolling-update check. The default is to perform a batch-update check.

  **Note:** This parameter is only supported on a cluster with eight or more nodes.

- `[-nodes <nodename> | local], ...` - Nodes
  - Specifies the nodes that are to be validated.

Examples

The following example shows the validate operation:

```
cluster1::> cluster image validate -version 8.3
```

It can take several minutes to complete validation...

cluster image package commands

Manage the cluster image package repository

cluster image package delete

Remove a package from the cluster image package repository

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The cluster image package delete command deletes the specified version of the package from the package repository. The associated information about the package is also deleted from the update database.

Parameters
-version <text> - Version To Be Deleted

  Specifies the package version that is to be deleted.

Examples
The following example deletes the package with version 8.3:

  cluster1::> cluster image package delete -version 8.3
  Package Delete Operation Completed Successfully

cluster image package get

Fetch a package file from a URL into the cluster image package repository

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The cluster image package get command fetches a Data ONTAP package file specified by the URL into the cluster. The package is stored in the cluster package repository and the information from the package is stored in the update database.

Parameters
-url <text> - Package URL

  Specifies the URL from which to get the package.
**Examples**
The following example displays how to get a package from a URL:

```plaintext
cluster1::> cluster image package get -url http://example.com/image.tgz
```

### cluster image package show-repository

Display information about packages available in the cluster image package repository

**Availability:** This command is available to cluster administrators at the **admin** privilege level.

**Description**
The `cluster image package show-repository` command displays the package versions that are in the cluster package repository. By default, the command displays the following information:

- Package version

**Parameters**

```plaintext
{-fields <fieldname>, ...}
```

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

```plaintext
{-detail}
```

This parameter specifies that detailed information should be displayed.

```plaintext
{-instance}
```

If you specify the `-instance` parameter, the command displays detailed information about all fields.

```plaintext
{-download-ver <text> - Downloaded Version}
```

Displays packages with the specified download version.

```plaintext
{-component-name <text>, ... - Component Name}
```

Displays packages for the specified component.

```plaintext
{-component-version <text>, ... - Component Version}
```

Displays packages with the specified component version.

```plaintext
{-package-build-time <MM/DD/YYYY HH:MM:SS> - Package Build Time}
```

Displays packages with the specified build time.

**Examples**
The following example displays the packages in the cluster package repository:

```plaintext
cluster1::> cluster image package show-repository
Package Version Package Build Time
------------------ ------------------
8.3 9/12/2014 10:27:33
```

### cluster kernel-service commands

Display and manage the cluster kernel services

Commands and methods used to manage the distributed kernel services of the cluster.
cluster kernel-service show

Display cluster service state in the kernel

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
The `cluster kernel-service show` command displays the following information from the master node for each node in the cluster:

- Node name
- The quorum status of that node
- The availability status of that node
- The operational status of that node

Parameters

`{-fields <fieldname>, ...}`

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

`{-instance}`

If you specify the `-instance` parameter, the command displays detailed information about all fields.

`{-master-node <nodename>|local}` - Node

The node in the cluster where the information be being reported from. If this parameter is not specified, the command displays information about all nodes in the cluster.

`{-cluster-node <text>}` - Cluster Node

The node in the cluster that the information listed is regarding. If this parameter is specified, the command displays information only about the nodes with the specified state value.

`{-status-quorum {out of quorum|in quorum}}` - Quorum Status

The quorum status of the node specified by `-cluster-node`. If this parameter is specified, the command displays information only about the nodes with the specified state value.

`{-status-avail {false|true|unknown}}` - Availability Status

The availability status of the node specified by `-cluster-node`. If this parameter is specified, the command displays information only about the nodes with the specified state value.

`{-status-oper {unknown|operational|not-operational}}` - Operational Status

The operational status of the node specified by `-cluster-node`. If this parameter is specified, the command displays information only about the nodes with the specified state value.

Examples

The following example displays information about all nodes in the cluster:

```
cluster1::*> cluster kernel-service show
Master            Cluster           Quorum        Availability  Operational
Node              Node              Status        Status        Status
----------------- ----------------- ------------- ------------- -------------
cluster1-01       cluster1-01       in-quorum     true          operational
cluster1-02       cluster1-02       in-quorum     true          operational
2 entries were displayed.
```

```
cluster1::*> cluster kernel-service show -instance

Master Node: cluster1-01
```
cluster identity commands

Manage the cluster's attributes, including name and serial number

cluster identity modify

Modify the cluster's attributes

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The cluster identity modify command changes a cluster's identity information.

Parameters

[-name <Cluster name>] - Cluster Name
Use this parameter to specify a new name for the cluster.
- The name must contain only the following characters: A-Z, a-z, 0-9, "," or ".".
- The first character must be one of the following characters: A-Z or a-z.
- The last character must be one of the following characters: A-Z, a-z or 0-9.
- The maximum supported length is 44 characters.
- The system reserves the following names: "all", "cluster", "local" and "localhost".

[-location <text>] - Cluster Location
Use this parameter to specify the physical location of the cluster. For example, "Lab 5".

[-contact <text>] - Cluster Contact
Use this parameter to specify contact information for the cluster, such as a name or email address.

Examples
The following example renames the current cluster to *cluster2*:

```
cluster1::> cluster identity modify -name cluster2
```

cluster identity show

Display the cluster's attributes including Name, Serial Number, Cluster UUID, Location and Contact

Availability: This command is available to cluster administrators at the admin privilege level.
Description
The `cluster identity show` command displays the identity information of the cluster.

Examples
The following example displays the cluster's UUID, name, serial number, location and contact information:

```
cluster1::> cluster identity show
    Cluster UUID: 1cd8a442-86d1-11e0-ae1c-123478563412
    Cluster Name: cluster1
    Cluster Serial Number: 1-80-123456
    Cluster Location: Lab2
    Cluster Contact: jsmith@example.com

cluster1::>
```

The following example displays the cluster's UUID, name, serial number, location, contact information, and RDB UUID:

```
cluster1::> set -privilege diagnostic
Warning: These diagnostic commands are for use by NetApp personnel only.
Do you want to continue? {y|n}: y
cluster1::*> cluster identity show
    Cluster UUID: 1cd8a442-86d1-11e0-ae1c-123478563412
    Cluster Name: cluster1
    Cluster Serial Number: 1-80-123456
    Cluster Location: Lab2
    Cluster Contact: jsmith@example.com
    RDB UUID: 1cd8f3bf-86d1-11e0-ae1c-123478563412

cluster1::*>
```

**cluster log-forwarding commands**
Manage the cluster's log forwarding configuration

**cluster log-forwarding create**
Create a log forwarding destination

**Availability**: This command is available to `cluster` administrators at the `admin` privilege level.

**Description**
The `cluster log-forwarding create` command creates log forwarding destinations for remote logging.

**Parameters**

- `destination <Remote InetAddress>` - Destination Host
  Host name or IPv4 or IPv6 address of the server to forward the logs to.

- `[port <integer>]` - Destination Port
  The port that the destination server listen on.

- `[protocol {udp-unencrypted|tcp-unencrypted|tcp-encrypted}]` - Log Forwarding Protocol
  The protocols are used for sending messages to the destination. The protocols can be one of the following values:
  - `udp-unencrypted` - User Datagram Protocol with no security
- `tcp-unencrypted` - Transmission Control Protocol with no security

`[-verify-server [true|false]]` - Verify Destination Server Identity
When this parameter is set to `true`, the identity of the log forwarding destination is verified by validating its certificate. The value can be set to `true` only when the `tcp-encrypted` value is selected in the protocol field.

`[-facility <Syslog Facility>]` - Syslog Facility
The syslog facility to use for the forwarded logs.

`[-force [true]]` - Skip the Connectivity Test
Normally, the `cluster log-forwarding create` command checks that the destination is reachable via an ICMP ping, and fails if it is not reachable. Setting this value to `true` bypasses the ping check so that the destination can be configured when it is unreachable.

**Examples**
This example causes audit logs to be forwarded to a server at address 192.168.0.1, port 514 with USER facility.

```
cluster1::> cluster log-forwarding create -destination 192.168.0.1 -port 514 -facility user
```

**cluster log-forwarding delete**
Delete a log forwarding destination

**Availability:** This command is available to `cluster` administrators at the `admin` privilege level.

**Description**
The `cluster log-forwarding delete` command deletes log forwarding destinations for remote logging.

**Parameters**
- `destination <Remote InetAddress>` - Destination Host
  Host name or IPv4 or IPv6 address of the server to delete the forwarding entry for.
- `port <integer>` - Destination Port
  The port that the destination server listen on.

**Examples**
This example deletes the forwarding of all logs to the server at address 1.1.1.1, port 514.

```
cluster1::> cluster log-forwarding delete -destination 1.1.1.1 -port 514
```

**cluster log-forwarding modify**
Modify log forwarding destination settings

**Availability:** This command is available to `cluster` administrators at the `admin` privilege level.

**Description**
The `cluster log-forwarding modify` command modifies log forwarding destinations for remote logging.
Parameters

-destination <Remote InetAddress> - Destination Host
  The host name or IPv4 or IPv6 address of the server to be modified.

-port <integer> - Destination Port
  The port that the destinations servers listen on.

-verify-server {true|false} - Verify Destination Server Identity
  When this parameter is set to true, the identity of the log forwarding destination is verified by validating its certificate. The value can be set to true only when the tcp-encrypted value is selected in the protocol field.

-facility <Syslog Facility> - Syslog Facility
  The syslog facility to use for the forwarded logs.

Examples

This example modifies the facility of audit logs that are forwarded to the destination server at address 192.168.0.1, port 514.

```
cluster1::> cluster log-forwarding modify -destination 192.168.0.1 -port 514 -facility local1
```

**cluster log-forwarding show**

Display log forwarding destinations

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**

The `cluster log-forwarding show` command displays log forwarding information:

- Destination (IPv4/IPv6/hostname)
- Port number
- List of log classes
- Facility

**Parameters**

```
[-fields <fieldname>, ...]
```

If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

```
[-instance]
```

If you specify the -instance parameter, the command displays detailed information about all fields.

```
[-destination <Remote InetAddress>] - Destination Host
```

If this optional parameter is specified, the command displays information about the forwarding destinations with the specified host name, IPv4 or IPv6 address.

```
[-port <integer>] - Destination Port
```

If this optional parameter is specified, the command displays information about the forwarding destinations with the specified ports.
[-protocol \{udp-unencrypted\|tcp-unencrypted\|tcp-encrypted\}] - Log Forwarding Protocol
  If this optional parameter is specified, the command displays information about the forwarding destinations
  with the specified protocols.

[-verify-server \{true\|false\}] - Verify Destination Server Identity
  If this optional parameter is specified, the command displays information about the forwarding destinations
  with the specified verify-server values.

[-facility <Syslog Facility>] - Syslog Facility
  If this optional parameter is specified, the command displays information about the forwarding destinations
  with the specified facility.

**cluster peer commands**

Manage cluster peer relationships

**cluster peer create**

Create a new cluster peer relationship

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**
The `cluster peer create` command establishes a peer relationship between two clusters. Cluster peering enables
independent clusters to coordinate and exchange data.

Before creating a new cluster peer relationship, make sure that both clusters are individually healthy and that there are no other
peer relationships between the two clusters that might interfere with the new relationship.

You can create a cluster peer relationship using the IPv4 or IPv6 protocol. You may not use both protocols within a single
relationship.

Use the `cluster show` and `cluster peer show` commands on each cluster to display health, peering eligibility, and peering
information about the two clusters.

**Parameters**

- `-peer-addr <Remote InetAddress>, ...` - Remote Intercluster Addresses
  
  Use this parameter to specify the names or IP addresses of the logical interfaces used for intercluster
  communication. Separate the addresses with commas.

  The addresses you provide here are associated with the remote cluster until you modify or delete the
  relationship, regardless of whether the addresses are valid. Make sure to provide addresses which you know
  will remain available on the remote cluster. You can use the hostnames of the remote cluster's intercluster
  addresses, the IP addresses of the remote cluster's intercluster LIFs or both.
[-username <text>] - Remote User Name

Use this optional parameter to specify a username that runs a reciprocal `cluster peer create` command on the peered cluster. If you choose not to use the reciprocal creation option, by not supplying a username for reciprocal creation, you must run `cluster peer create` again on the remote cluster to complete the peering relationship.

If you specify the username for the remote cluster, you will be prompted to enter the associated remote password. These credentials are not stored, they are used only during creation to authenticate with the remote cluster and to enable the remote cluster to authorize the peering request. The provided username's profile must have access to the console application in the remote cluster.

Use the `security login role show` and `security login show` commands on each cluster to find user names and their privilege levels.

[-no-authentication [true]] - Do Not Use Authentication

Use this optional parameter when omitting the `-username` parameter to indicate that you will create an unauthenticated peering relationship.

[-timeout <integer>] - Operation Timeout (seconds) (privilege: advanced)

Use this optional parameter to specify a timeout value for peer communications. Specify the value in seconds. The default timeout value is 60 seconds.

[-address-family {ipv4|ipv6}] - Address Family of Relationship

Use this optional parameter to specify the address family of the cluster peer relationship. The default is based on existing relationships, existing local intercluster LIFs belonging to a particular address-family, and the addresses supplied to the `cluster peer create` command.

[-offer-expiration <MM/DD/YYYY HH:MM:SS>] - Passphrase Match Deadline

Specifying `cluster peer create` normally creates an offer to establish authentication with a cluster that is a potential cluster peer to this cluster. Such offers expire unless they are accepted within some definite time. Use this optional parameter to specify the date and time at which this offer should expire, the time after which the offer will no longer be accepted.

[-rpc-connect-timeout <integer>] - Timeout for RPC Connect (seconds) (privilege: advanced)

Use this optional parameter to specify a timeout value for the RPC connect during peer communications. Specify the value in seconds. The default timeout value is 10 seconds.

[-update-ping-timeout <integer>] - Timeout for Update Pings (seconds) (privilege: advanced)

Use this optional parameter to specify a timeout value for pings while updating remote cluster information. Specify the value in seconds. The default timeout value is 5 seconds. This parameter applies only to cluster peer relationships using the IPv4 protocol.

[-ipspace <IPspace>] - IPspace for the Relationship

Use this optional parameter to specify the IPspace within which the cluster peering relationship is to operate. The default is to use the 'Default' IPspace.

[-local-name <Cluster name>] - Peer Cluster Local Name

Use this optional parameter to specify a unique local name to identify the remote cluster that is being peered. The local name must conform to the same rules as a cluster name. The default value is the remote cluster name.

---

**Examples**

This example creates a peer relationship between cluster1 and cluster2. This reciprocal create executes the create command on both the local cluster and the remote cluster. The cluster peer create command can use the hostnames of cluster2's intercluster addresses, the IP addresses of cluster2's intercluster LIFs, or both. Note that the admin user's password was typed at the prompt, but was not displayed.
cluster1::> cluster peer create -peer-addrs cluster2-d2, 10.98.234.246 -username admin
Remote Password:

cluster1::> cluster peer show -instance

<table>
<thead>
<tr>
<th>Peer Cluster Name: cluster2</th>
</tr>
</thead>

<tr>
<td>Guidance for When Encryption Should Be Used: never</td>
</tr>
</tbody>
</table>

This example shows coordinated peer creation. The `cluster peer create` command was issued locally on each cluster. This does not require you to provide the username and password for the remote cluster. There is a password prompt, but if you are logged in as the admin user, you may simply press enter.

cluster1::> cluster peer create -peer-addrs cluster2-d2, 10.98.234.246 -no-authentication
Remote Password:

cluster1::> cluster peer show

<table>
<thead>
<tr>
<th>Peer Cluster Name: cluster2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cluster Serial Number: 1-80-123456</td>
</tr>
<tr>
<td>Availability: Available</td>
</tr>
<tr>
<td>Authentication: absent</td>
</tr>
</tbody>
</table>

cluster2::> cluster peer create -peer-addrs cluster1-d2 -no-authentication
Remote Password:

cluster2::> cluster peer show

<table>
<thead>
<tr>

</tr>
<tr>
<td>Availability: Available</td>
</tr>
<tr>
<td>Authentication: absent</td>
</tr>
</tbody>
</table>

This example shows a reciprocal cluster peer create over IPv6 addresses, that establishes a cluster peer relationship with an IPv6 address family.

cluster1::> cluster peer create -peer-addrs FD20:8B1E:B255:C222:6A17:0BBE:E92C:4523 -username admin
Remote Password:

cluster1::> cluster peer show -instance

| Address Family of Relationship: ipv6 |
| Peer Cluster Name: cluster2 |
| Availability of the Remote Cluster: Available |
| Remote Cluster Name: cluster2 |
| Cluster Serial Number: 1-80-123456 |
| Address Family of Relationship: ipv6 |
| Authentication Status Administrative: no-authentication |
| Authentication Status Operational: absent |
| Last Update Time: 02/05 21:05:41 |
| IPspace for the Relationship: Default |
| Guidance for When Encryption Should Be Used: never |
This example shows creation of an authenticated peering relationship. It is an example of using the coordinated method to create a cluster peer relationship. The `cluster peer create` command is issued locally on each cluster. Before executing this pair of commands, a passphrase to be used with the commands is chosen and given at the prompts. The passphrase can be any text; it is prompted for twice on each cluster, and all four copies of the passphrase must agree. The passphrase does not echo on the screen. The passphrase must be longer than the minimum length as specified by the `cluster peer policy` on both clusters.

```
cluster1::> cluster peer create -peer-addrs cluster2-d2, 10.98.234.246
Enter the passphrase:
Enter the passphrase again:
Notice: Now use the same passphrase in the "cluster peer create" command in the other cluster.
cluster1::> cluster peer show
Peer Cluster Name         Cluster Serial Number Availability   Authentication
------------------------- --------------------- -------------- --------------
cluster2                  -                     Unavailable    pending
```

```
cluster2::> cluster peer create -peer-addrs cluster1-d2
Enter the passphrase:
Enter the passphrase again:
cluster2::> cluster peer show
Peer Cluster Name         Cluster Serial Number Availability   Authentication
------------------------- --------------------- -------------- --------------
cluster1                  1-80-654321           Available      ok
```

This example creates a peer relationship between cluster1 and cluster2. This reciprocal create executes the create command on both the local cluster and the remote cluster. The `cluster peer create` command can use the hostnames of cluster2's intercluster addresses, the IP addresses of cluster2's intercluster LIFs or both. Note that the admin user's password was typed at the prompt, but was not displayed. The `--local-name` parameter is specified to create a local name used to identify the peer cluster in cases where the name of the peer cluster is not unique or not descriptive.

```
cluster1::> create -peer-addrs 10.98.191.193 -username admin -local-name locallyUniqueName
cluster1::> cluster peer show
Peer Cluster Name         Cluster Serial Number Availability   Authentication
------------------------- --------------------- -------------- --------------
locallyUniqueName                1-80-000011           Available      absent
cluster1::> cluster peer show -instance
Peer Cluster Name: locallyUniqueName
Remote Intercluster Addresses: 10.98.191.193
Availability of the Remote Cluster: Available
Remote Cluster Name: cluster2
Active IP Addresses: 10.98.191.193
Cluster Serial Number: 1-80-000011
Address Family of Relationship: ipv4
Authentication Status Administrative: no-authentication
Authentication Status Operational: absent
Last Update Time: 02/05 21:05:41
IPspace for the Relationship: Default
Guidance for when Encryption Should Be Used: never
```

**cluster peer delete**

Delete a cluster peer relationship

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**
The `cluster peer delete` command removes a peering relationship. It removes the relationship records, state data, and all associated jobs.

Before removing the relationship, the command verifies that no resources depend on the relationship. For example, if any SnapMirror relationships exist, the command denies the request to delete the peering relationship. You must remove all dependencies for the deletion to succeed. The `cluster peer delete` command removes only the local instance of the peer relationship. An administrator in the peer cluster must use the `cluster peer delete` command there as well to completely remove the relationship.

**Parameters**
- `-cluster <text>` - Peer Cluster Name
  
  Use this parameter to specify the peering relationship to delete by specifying the name of the peered cluster.

**Examples**

This example shows a failed deletion due to a SnapMirror dependency.

```bash
cluster2::> cluster peer delete -cluster cluster1
Error: command failed: Unable to delete peer relationship. Reason: A SnapMirror source exists in this cluster
```

---

**cluster peer modify**

Modify cluster peer relationships

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**
The `cluster peer modify` command modifies the attributes of a peering relationship. When you modify a peer relationship and specify `-peer-addrs`, all of the remote addresses must respond, must be intercluster addresses, and must belong to the remote cluster that is being modified; or the modification request is denied.

**Parameters**
- `-cluster <text>` - Peer Cluster Name
  
  Use this parameter to specify the peering relationship to modify by specifying the name of the peered cluster.

  [-`-peer-addrs <Remote InetAddress>, ...`] - Remote Intercluster Addresses
  
  Use this parameter to specify the names or IP addresses of the logical interfaces used for intercluster communication. Separate the addresses with commas. The list of addresses you provide replaces the existing list of addresses.

  [-`-timeout <integer>`] - Operation Timeout (seconds) (privilege: advanced)
  
  Use this parameter to specify a timeout value for peer communications. Specify the value in seconds.

  [-`-address-family {ipv4 | ipv6}`] - Address Family of Relationship
  
  Use this parameter to specify the address family of the names specified with the peer-addrs parameter.
[-auth-status-admin {no-authentication|revoked|use-authentication}] - Authentication Status

Administrative
Use this parameter to adjust the authentication in use for the peer relationship. The defined values for this field are as follows.

- no-authentication - The cluster peer relationship uses no authentication.
- use-authentication - The cluster peer relationship is to be authenticated. After you use this value, you will be prompted for a passphrase to be used in determining a new authentication key, just as in the authenticated `cluster peer create` command.
- revoked - The cluster peer relationship is no longer to be trusted. Peering communication with this cluster peer is suspended until the two clusters set their auth-status-admin attributes either both to no-authentication or both to use-authentication.

Changes should be reflected on both clusters involved in a peering relationship.

[-rpc-connect-timeout <integer>] - Timeout for RPC Connect (privilege: advanced)
Use this optional parameter to specify a timeout value for the RPC connect during peer communications. Specify the value in seconds.

[-update-ping-timeout <integer>] - Timeout for Update Pings (privilege: advanced)
Use this optional parameter to specify a timeout value for pings while updating remote cluster information. Specify the value in seconds. This parameter applies only to cluster peer relationships using the IPv4 protocol.

[-ipspace <IPspace>] - IPspace for the Relationship
Use this optional parameter to specify that cluster peering communication for this remote cluster is to be done using local intercluster LIFs that are on ports in the named IPspace.

Examples
This example modifies the peering relationship to use a new IP address in the remote cluster for intercluster communications and revoke authentication.

View existing cluster peer configuration using following command:

```
cluster1::> cluster peer show -instance
```

```
Peer Cluster Name: cluster2
Remote Intercluster Addresses: cluster2-d2, 10.98.234.246
Availability of the Remote Cluster: Available
Remote Cluster Name: cluster2
Active IP Addresses: 10.98.234.246, 10.98.234.243
Cluster Serial Number: 1-80-123456
Remote Cluster Nodes: cluster2-01, cluster2-02
Remote Cluster Health: true
Unreachable Local Nodes: -
Address Family of Relationship: ipv4
Authentication Status Administrative: use-authentication
Authentication Status Operational: ok
Last Update Time: 02/05 21:05:41
IPspace for the Relationship: Default
Guidance for when Encryption Should Be Used: as-possible
```

Modify the cluster peer configuration using following command:

```
cluster1::> cluster peer modify -cluster cluster2 -peer-addrs cluster2-d2,10.98.234.264 -auth-status-admin revoked
```

Warning: This will discard the authentication key.
Warning: You are removing authentication from the peering relationship with cluster "cluster2". Use the "cluster peer modify" command on cluster "cluster2" with the "-auth-status-admin no-authentication" parameter to complete authentication removal from the peering relationship.

Do you want to continue?{y|n}: y

cluster peer modify-local-name

Modify the local name for a cluster peer

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The cluster peer modify-local-name command modifies the local name for a remote cluster. The new local name must be unique among all the local names for the remote clusters with which this cluster is peered.

Parameters

- **name <text>** - Cluster Peer Name
  
  Use this parameter to specify the existing local name for a peer cluster.

- **new-name <Cluster name>** - Cluster Peer Local Name
  
  Use this parameter to specify the new local name of the peer cluster. The new local name must conform to the same rules as a cluster name.

Examples

```
cluster2::> cluster peer modify-local-name -name cluster1 -new-name cluster1A
```

cluster identity modify on page 45

cluster peer ping

Initiate intercluster connectivity test

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The cluster peer ping command displays the status of the network mesh used by the peering relationship. The command checks the network connection to each remote IP address known by the cluster. This includes all intercluster addresses. It is possible for a known address to be not present during the ping. These addresses are not checked, but the absence is temporary.

The most useful parameters for diagnosing problems are **-count** and **-packet-size**. Use the **-count** and **-packet-size** parameters to diagnose problems similarly to how you use them with the standard ping utility.
To display network connection status within a cluster, use the `network ping` command.

**Parameters**

```
[-fields <fieldname>, ...]
```

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

```
[-instance]
```

If you specify the `-instance` parameter, the command displays detailed information about all fields.

```
-originating-node {<nodename>|local} - Node that Initiates Ping
```

Use this parameter to send the ping from the node you specify.

```
-destination-cluster <Cluster name> - Cluster to Ping
```

Use this parameter to specify the peer cluster you wish to ping.

```
-destination-node <Peer Node Name> - Node to Ping in Destination Cluster
```

Use this parameter to specify a specific node in the destination cluster to ping.

```
-ip-address <IP Address> - Active IP Address
```

Use this parameter to specify the active IP address you wish to ping.

```
-count <integer> - Ping Count
```

Use this parameter to specify the number of requests to be sent to the destination.

```
-status {unknown_node|internal_error|unreachable|session_reachable|interface_reachable} - Status of Ping Operation
```

Use this parameter to display only ping results that have the status you specify.

```
-timeout <integer> - Ping Timeout in Seconds
```

Use this parameter to specify a timeout value in seconds for the ping operation.

```
-packet-size <integer> - Size of Packet
```

Use this parameter to specify the number of data bytes to be sent in the ping packet.

```
-ttl <integer> - Time to Live/ Number of Hops
```

Use this parameter to specify the maximum number of network hops a packet may make before it is considered a failure.

```
-response-time <double> - Response Time (ms)
```

Use this parameter to display only nodes that have the response time (in milliseconds) that you specify. This parameter is most useful when specified with a range of values, such as `>500`

**Examples**

This example shows a ping of cluster1 and cluster2 from cluster2. All nodes are reachable.

```
cluster2::> cluster peer ping
Node: node1          Destination Cluster: cluster2
                        Destination Node IP Address       Count  TTL  RTT(ms) Status
----------------------- -------------------------- ----- ---- ------ -------------------------
node1                  10.98.228.230        1  255   0.209 interface_reachable
node2                  10.98.228.234        1  255   0.42   interface_reachable
```

```
Node: node2          Destination Cluster: cluster2
                        Destination Node IP Address       Count  TTL  RTT(ms) Status
----------------------- -------------------------- ----- ---- ------ -------------------------
node1                  10.98.228.230        1  255   0.358 interface_reachable
node2                  10.98.228.234        1  255   0.17   interface_reachable
```

```
Node: node1          Destination Cluster: cluster1
                        Destination Node IP Address       Count  TTL  RTT(ms) Status
----------------------- -------------------------- ----- ---- ------ -------------------------
node3                  10.98.229.22         1  255   0.336 interface_reachable
node4                  10.98.229.29         1  255   0.354 interface_reachable
```

```
Node: node2          Destination Cluster: cluster1
```

cluster peer show

Display peer cluster information

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The cluster peer show command displays information about the peering relationships between the current cluster and other clusters. Cluster peering enables independent clusters to coordinate and exchange data.

Parameters

[-fields <fieldname>, ...]
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use -fields ? to display the fields to specify.

[-instance]
If you specify the -instance parameter, the command displays detailed information about all fields.

[-cluster <text>] - Peer Cluster Name
Selects the peered clusters that match this parameter value.

[-cluster-uuid <UUID>] - Cluster UUID (privilege: advanced)
Selects the peered clusters that match this parameter value.

[-peer-addrs <Remote InetAddress>, ...] - Remote Intercluster Addresses
Selects the peered clusters that match this parameter value (remote-host name or IP address).

[-availability <availability>] - Availability of the Remote Cluster
Selects the peered clusters that match this parameter value. This parameter can have four different values:

- Available - The peer cluster availability status will be Available only if all the nodes in the local cluster are able to contact all the nodes in the remote cluster.
- Partial - The peer cluster availability status will be Partial only if some nodes in the local cluster are not able to contact some or all nodes in the peer cluster.
- Unavailable - The peer cluster availability status will be Unavailable only if all the nodes in the local cluster are not able to contact any node in the peer cluster.
- Pending - The peer cluster availability status will be Pending while the system is creating in-memory health data.

Note: If one or more nodes in the local cluster are offline or unreachable, then those nodes are not used to determine the availability status for the remote nodes.

[-rcluster <text>] - Remote Cluster Name
Selects the peered clusters that match this parameter value.
[-ip-addrs <Remote InetAddress>, ...] - Active IP Addresses
Selects the peered clusters that match this parameter value.

[-serialnumber <Cluster Serial Number>] - Cluster Serial Number
Selects the peered clusters that match this parameter value.

[-remote-cluster-nodes <text>, ...] - Remote Cluster Nodes
Selects the peered clusters that match this parameter value.

[-remote-cluster-health (true|false)] - Remote Cluster Health
Selects the peered clusters that match this parameter value.
  * true - This means that there is cluster quorum in the peer cluster.
  * false - This means that there is no cluster quorum in the peer cluster.

[-unreachable-local-nodes <text>, ...] - Unreachable Local Nodes
Selects the peered clusters that match this parameter value.

[-timeout <integer>] - Operation Timeout (seconds) (privilege: advanced)
Selects the peered clusters that match this parameter value.

[-address-family {ipv4|ipv6}] - Address Family of Relationship
Selects the peered clusters that have a relationship established using this protocol.

[-auth-status-admin {no-authentication|revoked|use-authentication}] - Authentication Status Administrative
Selects the peered clusters that match this parameter value, which must be chosen from the following values.
  * no-authentication - The cluster peer relationship uses no authentication.
  * use-authentication - The cluster peer relationship is authenticated.
  * revoked - The cluster peer relationship is revoked until agreement can be reached.

[-auth-status-operational {ok|absent|pending|expired|revoked|declined|refused|ok-and-offer|
  absent-but-offer|revoked-but-offer|key-mismatch|intent-mismatch|incapable}] - Authentication Status Operational
Selects the peered clusters that match this parameter value, which must be one of the following values.
  * ok - The clusters both use authentication and they have agreed on an authentication key.
  * absent - The clusters agree not to use authentication.
  * pending - This cluster has made an outstanding offer to authenticate with the other cluster, but agreement has not yet been reached.
  * expired - This cluster's offer to authenticate with the other cluster expired before agreement was reached.
  * revoked - This cluster has revoked any prior authentication agreement.
  * declined - The other cluster has revoked the authentication agreement and is declining to communicate with this cluster.
  * refused - The other cluster actively refuses the communication attempts, perhaps because its part of the peering relationship has been deleted.
  * ok-and-offer - The clusters agree on an authentication key and are using it. In addition, this cluster has made an outstanding offer to re-authenticate with the other cluster.
  * absent-but-offer - The clusters currently agree that neither side requires authentication of the other, but this cluster has made an outstanding offer to authenticate.
• revoked-but-offer - This cluster has revoked any authentication agreement, but it has made an outstanding offer to authenticate.

• intent-mismatch - The two clusters disagree on whether authentication is required.

• key-mismatch - The two clusters both believe that they are authenticated, but one of the shared secrets has become corrupted.

• incapable - The other cluster is no longer running a version of Data ONTAP that supports authenticated cluster peering.

[-rpc-connect-timeout <integer>] - Timeout for RPC Connect (privilege: advanced)
Selects the peered clusters that match this parameter value.

[-update-ping-timeout <integer>] - Timeout for Update Pings (privilege: advanced)
Selects the peered clusters that match this parameter value.

[-last-updated <MM/DD/YYYY HH:MM:SS>] - Last Update Time
Selects the peered clusters that match this parameter value.

[-ipspace <IPspace>] - IPspace for the Relationship
Selects the peered clusters whose relationships are to cross the named local IPspace. The default value is the IPspace name "Default". In relationships created before ONTAP 8.3.1, the initial value is "-" and is not updated to "Default" until an action is taken on a cluster peer relationship, such as creating, modifying, or deleting a relationship.

Examples
This example shows the output of the cluster peer show command when all nodes in the local cluster are able to contact all nodes in the remote peer cluster. Additionally, the peer relationship is authenticated and operating correctly.

```
cluster1::> cluster peer show
Peer Cluster Name  Cluster Serial Number Availability Authentication
----------------- --------------------- -------------- --------------
ciuster2           1-80-123456       Available      ok
```

Detailed information for this scenario is shown below.

```
cluster1::> cluster peer show -instance
Peer Cluster Name: cluster2
Remote Intercluster Addresses: cluster2-d2, 10.98.234.246
Availability of the Remote Cluster: Available
Remote Cluster Name: cluster2
Active IP Addresses: 10.98.234.246, 10.98.234.243
Remote Cluster Nodes: cluster2-01, cluster2-02
Remote Cluster Health: true
Unreachable Local Nodes: -
Address Family of Relationship: ipv4
Authentication Status Administrative: use-authentication
Authentication Status Operational: ok
Last Update Time: 02/05 21:05:41
IPspace for the Relationship: Default
```

This example shows the output of the cluster peer show command when some nodes in the local cluster are not able to contact some or all of the nodes in the remote peer cluster.

```
cluster1::> cluster peer show
Peer Cluster Name  Cluster Serial Number Availability Authentication
----------------- --------------------- -------------- --------------
ciuster2           1-80-123456       Available      ok
```

Detailed information for this scenario is shown below.

```
cluster1::> cluster peer show -instance
Peer Cluster Name: cluster2
Remote Intercluster Addresses: cluster2-d2, 10.98.234.246
Availability of the Remote Cluster: Available
Remote Cluster Name: cluster2
Active IP Addresses: 10.98.234.246, 10.98.234.243
Remote Cluster Nodes: cluster2-01, cluster2-02
Remote Cluster Health: true
Unreachable Local Nodes: -
Address Family of Relationship: ipv4
Authentication Status Administrative: use-authentication
Authentication Status Operational: ok
Last Update Time: 02/05 21:05:41
IPspace for the Relationship: Default
```
This example shows the output of the cluster peer show command when some nodes in the local cluster cannot be contacted from the node where the command is executed, but all the other nodes including node on which command is executed are able to contact all nodes in the remote peer cluster.

```
cluster1::> cluster peer show
Peer Cluster Name               Cluster Serial Number Availability   Authentication
---------------------------------------- -------------- -------------
car2                              1-80-123456           Available      ok
```

Detailed information for this scenario is shown below.

```
cluster1::> cluster peer show -instance
Peer Cluster Name: car2
Remote Intercluster Addresses: car2-d2, 10.98.234.246
Availability of the Remote Cluster: Available
Remote Cluster Name: car2
Active IP Addresses: 10.98.234.246, 10.98.234.243
Cluster Serial Number: 1-80-123456
Remote Cluster Nodes: cluster2-01, cluster2-02
Remote Cluster Health: true
Unreachable Local Nodes: cluster1-01
Address Family of Relationship: ipv4
Authentication Status Administrative: use-authentication
Authentication Status Operational: ok
Last Update Time: 02/05 21:05:41
IPspace for the Relationship: Default
```

This example shows the output of the cluster peer show command when some nodes in the local cluster cannot be contacted from the node where the command is executed, and the node on which command is executed is also not able to contact the remote peer cluster.

```
cluster1::> cluster peer show
Peer Cluster Name               Cluster Serial Number Availability   Authentication
---------------------------------------- -------------- -------------
car2                              1-80-123456           Unavailable    ok
```

Detailed information for this scenario is shown below.

```
cluster1::> cluster peer show -instance
Peer Cluster Name: car2
Remote Intercluster Addresses: car2-d2, 10.98.234.246
Availability of the Remote Cluster: Unavailable
Remote Cluster Name: car2
Active IP Addresses: 10.98.234.246, 10.98.234.243
Cluster Serial Number: 1-80-123456
Remote Cluster Nodes: cluster2-01, cluster2-02
Remote Cluster Health: -
Unreachable Local Nodes: cluster1-01
Address Family of Relationship: ipv4
```

Commands: Manual Page Reference
This example shows the output of the cluster peer show command when all the nodes in the local cluster are not able to contact any nodes in the remote peer cluster.

```
cluster1::> cluster peer show

```

**Cluster Peer Connection Commands**

The connection directory

The `cluster peer connection` commands provide you with the ability to observe, and to some extent manage, the connections created on behalf of cluster peering, both for control and data access.
cluster peer connection show

Show current peering connections for a cluster

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The cluster peer connection show command displays information about the current TCP connections and how they are supporting the set of peering relationships.

Parameters

{-fields <fieldname>, ...}
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

{-instance}
If you specify the -instance parameter, the command displays detailed information about all fields.

{-cluster-name <text>} - Remote Cluster
Selects the connections associated with the named peered cluster.

{-node {<nodename>|local}} - Node
Selects the connections hosted by the given node.

{-connection-type {mgmt-client|mgmt-server|data}} - Cluster Peering Connection Type
Selects the connections of the named type. This parameter can have one of three different values:

• Mgmt-client - Management-plane client connections, created so that this node may make management-plane requests of other nodes.
• Mgmt-server - Management-plane server connections, over which this node services requests made by other nodes' mgmt-client connections.
• Data - Connections made between data-planes of different nodes.

{-index <integer>} - Index of Connection
Selects the connections with the given index value.

{-cluster-uuid <UUID>} - Cluster UUID (privilege: advanced)
Selects the connections to the cluster with the given cluster UUID.

{-auth-status-admin {no-authentication|revoked|use-authentication]} - Authentication Status Administrative
Selects connections to the peered clusters whose intended authentication matches this parameter value.

{-auth-status-operational {ok|absent|pending|expired|revoked|declined|refused|ok-and-offer|absent-but-offer|revoked-but-offer|key-mismatch|intent-mismatch|incapable]} - Authentication Status Operational
Selects connections to the peered clusters whose authentication state matches this parameter value.

{-authenticated {true|false}} - Authenticated
Selects connections that have been authenticated, or not, according to this parameter value.

{-port <integer>} - Network Port
Selects the connections that match this parameter value.

{-idle [<integer>h][<integer>m][<integer>s>] - Idle Time
Selects the connections whose idle times match this parameter value.
[-address <IP Address>] - Remote Network Address

Selects the connections that have this parameter value as the remote network address.

### Examples
This example shows the output of the cluster peer connection show command.

```
cluster1::> cluster peer connection show
Cluster Node               Connection Type  Auth  Encrypt Idle  Remote Address
------- -----------------  ---------------  ----- ------- ----  --------------
cluster2                      Authentication: ok
    node1
        data  true  true   6s    10.10.10.100
        data  true  true   7s    10.10.10.100
        data  true  true   20s   10.10.10.100
        data  true  true   11s   10.10.10.100
        data  true  true   7s    10.10.10.100
        data  true  true   7s    10.10.10.100
        data  true  true   20s   10.10.10.100
        data  true  true   11s   10.10.10.100
        data  true  true   7s    10.10.10.100
        data  true  true   7s    10.10.10.100
        data  true  true   11s   10.10.10.200
        data  true  true   11s   10.10.10.200
        data  true  true   48s   10.10.10.200
        data  true  true   48s   10.10.10.200
        data  true  true   37s   10.10.10.200
        data  true  true   37s   10.10.10.200

12 entries were displayed.
```

### cluster peer health commands

The health directory

### cluster peer health show

Check peer cluster health

**Availability:** This command is available to `cluster` administrators at the `admin` privilege level.

**Description**
The `cluster peer health show` command displays information about the health of the nodes in peer clusters from the perspective of the nodes in the local cluster. The command obtains health information by performing connectivity and status probes of each peer cluster’s nodes from each node in the local cluster.

To enable quick access to remote cluster health information, remote cluster health status is periodically checked and cached. These cached results enable users and system features to quickly assess the availability of remote resources. By default, this command accesses cached results. Use the `-bypass-cache true` option to force a current, non-cached check of remote cluster health.

**Parameters**

`[-fields <fieldname>, ...]`

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

`[-instance]`

If you specify the `-instance` parameter, the command displays detailed information about all fields.

`[-originating-node (<nodename>|local)] - Local Node`

Selects the node that matches this parameter value.

`[-destination-cluster <Cluster name>] - Peer Cluster`

Selects the cluster that matches this parameter value.
[-destination-node \texttt{<Peer Node Name>}] - Peer Node
Selects the node that matches this parameter value.

[-destination-cluster-uuid \texttt{<UUID>}] - Peer UUID
Selects the cluster that matches this parameter value.

[-data-ping \{\texttt{unknown_node|internal_error|unreachable|session_reachable|interface_reachable}\}] - Status of Data Ping Operation
Selects the nodes that match this parameter value.

[-icmp-ping \{\texttt{unknown_node|internal_error|unreachable|session_reachable|interface_reachable}\}] - Status of ICMP Ping Operation
Selects the nodes that match this parameter value.

[-node-health \{\texttt{true|false}\}] - RDB Health of the Node
Selects the nodes that match this parameter value (\texttt{true} means healthy).

[-cluster-health \{\texttt{true|false}\}] - Cluster Health
Selects the nodes that match this parameter value (\texttt{true} means healthy).

[-availability \{\texttt{true|false}\}] - Communication Indicator
Selects the nodes that match this parameter value (\texttt{true} means communicating).

[-bypass-cache \{\texttt{true|false}\}] - Bypass Cache and Determine Health
Bypasses cached results to determine current cluster health (\texttt{true} means bypass the cache). Cached results may not be current, but they are displayed more quickly.

[-last-updated \texttt{<MM/DD/YYYY HH:MM:SS>}] - Last Update Time
Selects the nodes that match this parameter value.

---

**Examples**

The following example shows typical output for this command in a cluster of two nodes that has a peer cluster of two nodes.

```
cluster1::> cluster peer health show
Node        Cluster-Name                 Node-Name
Ping-Status                RDB-Health Cluster-Health Availability
---------- --------------------------- --------- --------------- ------------
node1       cluster2                    node3
            Data: interface_reachable
            ICMP: interface_reachable true     true     true
            node4
            Data: interface_reachable
            ICMP: interface_reachable true     true     true
node2       cluster2                    node3
            Data: interface_reachable
            ICMP: interface_reachable true     true     true
            node4
            Data: interface_reachable
            ICMP: interface_reachable true     true     true
4 entries were displayed.
```

The following example shows detailed health information for node3 in cluster2 from the perspective of node1 in cluster1.

```
cluster1::> cluster peer health show -originating-node node1 -destination-cluster cluster2 -
destination-node node3 -instance

Local Node: node1
Peer Cluster: cluster2
Peer Node: node3
Peer UUID: 5e4befb2-1f36-11d0-98c9-123476563412
Status of Data Ping Operation: interface_reachable
Status of ICMP Ping Operation: interface_reachable
```
Cluster Peer Offer Commands

Manage offers to authenticate cluster peer relationships

The `cluster peer offer` commands provide you with the ability to manage the authentication offers that can be created by the `cluster peer create` and `cluster peer modify` commands.

- `cluster peer modify` on page 53

cluster peer offer cancel

Cancel the outstanding offer to authenticate with a peer cluster

**Availability:** This command is available to cluster administrators at the `admin` privilege level.

**Description**

The `cluster peer offer cancel` command cancels an outstanding offer to authenticate with a potentially peered cluster. After the command completes, the given cluster can no longer establish authentication using the given authentication offer.

**Parameters**

- `--cluster <text>` - Peer Cluster Name
  
  Use this parameter to specify which offer should be cancelled, by specifying the name of the cluster to which the offer is extended.

**Examples**

The following example cancels the authentication offer to cluster2.

```
cluster1::> cluster peer offer cancel --cluster cluster2
```

cluster peer offer modify

Modify an outstanding offer to authenticate with a peer cluster

**Availability:** This command is available to cluster administrators at the `admin` privilege level.

**Description**

The `cluster peer offer modify` command modifies the outstanding offer to authenticate with a potentially peered cluster. Every authentication offer has an expiration time, after which the offer will no longer be honored. This command is used to change that expiration time. To cancel the offer outright, use the `cluster peer offer cancel` command instead.

**Parameters**

- `--cluster <text>` - Peer Cluster Name
  
  Use this parameter to specify the offer to be modified by indicating the name of the cluster to which it has been extended.

  
  Use this parameter to specify the new expiration time for the offer.
Examples

This example modifies the expiration time for the authentication offer to push it out by an hour.

```
cluster1::> cluster peer offer show
Peer Cluster Name       Authentication Creation            Expiration
----------------------- -------------- ------------------- -------------------
cluster1::> cluster peer offer modify -cluster cluster2 -offer-expiration "7/23/2013 16:45:47"
cluster1::> cluster peer offer show
Peer Cluster Name       Authentication Creation            Expiration
----------------------- -------------- ------------------- -------------------
```

**cluster peer offer show**

Display outstanding offers to authenticate with a peer cluster

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**

The *cluster peer offer show* command displays information about authentication offers still pending with potential peer clusters. By default, the command displays information about all unexpired offers made by the local cluster.

To display detailed information about a specific offer, run the command with the `-cluster` parameter.

**Parameters**

```
{ [-fields <fieldname>, ...]  
  [-instance]]
```

- If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.
- If you specify the `-instance` parameter, the command displays detailed information about all fields.

```
[-cluster <text>] - Peer Cluster Name
```

Selects the offer that matches this parameter value.

```
[-auth-status-operational {ok|absent|pending|expired|revoked|declined|refused|ok-and-offer|absent-but-offer|revoked-but-offer|key-mismatch|intent-mismatch|incapable}] - Authentication Status Operational
```

Selects the offers that match this parameter value.

```
[-offer-creation <MM/DD/YYYY HH:MM:SS>] - Authentication Offer Creation Time
```

Selects the offers that match this parameter value.

```
[-offer-expiration <MM/DD/YYYY HH:MM:SS>] - Authentication Offer Expiration Time
```

Selects the offers that match this parameter value.

**Examples**

The following example displays information about the outstanding authentication offers:
cluster peer policy commands

Manage the policy configuration of the cross-cluster relationship facility

cluster peer policy modify

Modify the policy configuration for the cluster peering service

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The cluster peer policy modify command modifies the prevailing policy settings. One setting governs whether unauthenticated cluster peer relationships can exist. The other setting specifies a minimum length for passphrases.

Parameters
-\(-is-unauthenticated-access-permitted \{true|false\}\) - Is Unauthenticated Cluster Peer Access Permitted
  
  Use this parameter to specify whether unauthenticated peering relationships are allowed to exist. Setting the parameter value to true allows such relationships to exist. Setting the value to false prevents both the creation of unauthenticated peering relationships as well as the modification of existing peering relationships to be unauthenticated. Setting the value to false is not possible if the cluster currently is in any unauthenticated relationships.

-\(-passphrase-minlength <integer>\) - Passphrase Length Minimum

  Use this parameter to specify a minimum length for passphrases as given to the cluster peer create or cluster peer modify commands in the future. The default value for this parameter is 8.

Examples

This example modifies the peering policy to disallow unauthenticated intercluster communications.

```
cluster1::> cluster peer policy show
Is Unauthenticated Cluster Peer Communication Permitted: true
Minimum Length for a Passphrase: 8

cluster1::> cluster peer policy modify -is-unauthenticated-access-permitted false

cluster1::> cluster peer policy show
Is Unauthenticated Cluster Peer Communication Permitted: false
Minimum Length for a Passphrase: 8
```

Related references

- cluster peer create on page 49
- cluster peer modify on page 53

cluster peer policy show

Display the policy configuration for the cluster peering service

Availability: This command is available to cluster administrators at the admin privilege level.
Description
The cluster peer policy show command displays the prevailing cluster peer authentication policy. There are two policies at present: one to control whether any cluster peer relationships can be unauthenticated, and one to control the minimum length for a passphrase. If the policy is set to preclude unauthenticated peering relationships, then unauthenticated relationships cannot be created inadvertently. Passphrases of less than the minimum length may not be used. By default, this minimum length is set to 8, so passphrases must be 8 characters long or longer.

Examples
This example shows the cluster peer policy when unauthenticated relationships may not be created inadvertently.

```
cluster1::> cluster peer policy show
Is Unauthenticated Cluster Peer Communication Permitted:  false
Minimum Length for a Passphrase:  9
```

cluster quorum-service commands
Manage the quorum options of the cluster

cluster quorum-service options commands
The options directory

cluster quorum-service options modify
Modify the settings for cluster quorum-service

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
The cluster quorum-service options modify command modifies the values of cluster quorum services options.

Parameters
[-ignore-quorum-warning-confirmations {true|false}] - Whether or Not Warnings Are Enabled

Specifies whether cluster quorum warnings and confirmations should be ignored when cluster operations could negatively impact cluster quorum:

- Halting a node (system node halt)
- Rebooting a node (system node reboot)
- Issuing a planned takeover (storage failover takeover)

The default setting is false.

Examples
The following example shows the usage of this command:

```
cluster1::> set advanced
Warning: These advanced commands are potentially dangerous; use them only when directed to do so by NetApp personnel.
```
cluster quorum-service options show

Display the settings for cluster quorum-service

**Availability:** This command is available to cluster administrators at the *advanced* privilege level.

**Description**
The `cluster quorum-service options show` command displays the values of cluster quorum services options.

**Examples**
The following example demonstrates showing the state of ignore-quorum-warning-confirmations when it is false and true.

```bash
cluster1::*> set advanced
Warning: These advanced commands are potentially dangerous; use them only when directed to do so by NetApp personnel.
Do you want to continue? {y|n}: y
cluster1::*> cluster quorum-service options show
Ignore Quorum Warning Confirmations
-----------------------------------
false
```

**cluster ring commands**

Display information about cluster replication rings

**cluster ring show**

Display cluster node member's replication rings

**Availability:** This command is available to cluster administrators at the *advanced* privilege level.

**Description**
The `cluster ring show` command displays a cluster's ring-replication status. Support personnel might ask you to run this command to assist with troubleshooting.

**Parameters**

```
[-fields <fieldname>, ...]
```

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.
If you specify the -instance parameter, the command displays detailed information about all fields.

[-node <nodename>|local] - Node
Selects the rings that match this parameter value.

[-unitname mgmt|vldb|vifmgr|bcomd|crs|availd] - Unit Name
Selects the rings that match this parameter value. Possible values are:
  • mgmt - The management application
  • vldb - The volume location database
  • vifmgr - The virtual-interface manager
  • bcomd - The SAN management daemon
  • crs - The configuration replication service

[-online master|secondary|offline] - Status
Selects the rings that match this parameter value.

[-epoch <integer>] - Epoch
Selects the rings that match this parameter value.

[-master <nodename>] - Master Node
Selects the rings that match this parameter value.

[-local <nodename>] - Local Node
Selects the rings that match this parameter value.

[-db-e epoch <integer>] - DB Epoch
Selects the rings that match this parameter value.

[-db-trnxs <integer>] - DB Transaction
Selects the rings that match this parameter value.

[-num-online <integer>] - Number Online
Selects the rings that match this parameter value.

[-rdb-uuid <UUID>] - RDB UUID
Selects the rings that match this parameter value.

Examples
The following example displays information about all replication rings in a two-node cluster:

<table>
<thead>
<tr>
<th>Node</th>
<th>UnitName</th>
<th>Epoch</th>
<th>DB Epoch</th>
<th>DB Trnxs</th>
<th>Master</th>
<th>Online</th>
</tr>

Cluster Statistics Commands

Display cluster statistics

The `cluster statistics` command displays statistics of Data ONTAP 8 systems.

**cluster statistics show**

Display cluster-wide statistics

*Availability:* This command is available to `cluster` administrators at the `admin` privilege level.

**Description**

The `cluster statistics show` command displays the following information. Each item lists the current value and, if applicable, the change (delta) from the previous reported value.

- CPU busy percentage
- Average of CPU busy percentage (advanced privilege level only)
- Total number of NFS and CIFS operations
- Number of NFS operations
- Number of CIFS operations
- Number of cache operations (advanced privilege level only)
- Total amount of network data received (advanced privilege level only)
- Total amount of network data sent (advanced privilege level only)
- Number of packets received (advanced privilege level only)
- Number of packets sent (advanced privilege level only)
- Busy percentage for the data network
- Amount of data received on the data network
- Amount of data sent on the data network
- Busy percentage for the cluster network
- Amount of data received on the cluster network
- Amount of data sent on the cluster network
- Amount of data read from disk
- Amount of data written to disk

At the diagnostic privilege level, the command displays the following information:

- Average of CPU busy percentage
- CPU busy percentage
- Total number of operations
- Number of NFS operations
- Number of CIFS operations
- Number of Fcache operations
- Number of SpinFS operations
- Total amount of network traffic received
- Total amount of network traffic sent
- Percentage of data-network utilization
- Amount of data-network traffic received
- Amount of data-network traffic sent
- Percentage of cluster-network utilization
- Amount of cluster-network traffic received
- Amount of cluster-network traffic sent
- Amount of data read from disk
- Amount of data written to disk
- Number of packets received
- Number of packets sent

**Examples**

The following example displays cluster statistics:

```
cluster1::> cluster statistics show

<table>
<thead>
<tr>
<th>Counter</th>

<td>53.5MB/s:11s</td>
</tr>
</tbody>
</table>
```

**cluster time-service commands**

Manage cluster time services

**cluster time-service ntp commands**

Manage cluster Network Time Protocol (NTP) service
cluster time-service ntp server commands

The server directory

cluster time-service ntp server create

Add a NTP Server

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The cluster time-service ntp server create command associates the cluster with an external network time server for time correction and adjustment by using the Network Time Protocol (NTP).

The command resolves the time server host name to an IP address and performs several validation checks. If an error is detected during validation, it is reported.

The validation checks performed by this command include the following:

- The NTP replies to an NTP query with the specified protocol version.
- The NTP reply indicates that the external time server is synchronized to another time server.
- The distance and dispersion of the NTP reply from the "root" or source clock are within the required limits.

Parameters

-server <text> - NTP Server Host Name, IPv4 or IPv6 Address

This specifies the host name or IP address of the external NTP server that is to be associated with the cluster for time correction and adjustment.

[---version {3 | 4 | auto}] - NTP Version for Server (default: auto)

This optionally specifies the NTP protocol version that should be used for communicating with the external NTP server. If the external NTP server does not support the specified protocol version, time exchange cannot take place.

The supported values for this parameter include the following:

- 3 - Use NTP protocol version 3, which is based on Internet Standard Request For Comments (RFC) #1305.
- 4 - Use NTP protocol version 4, which is based on Internet Standard RFC #5905.
- auto - Have Data ONTAP select the NTP protocol version.

The default setting is auto.

[---is-preferred {true | false}] - Is Preferred NTP Server (default: false) (privilege: advanced)

This optionally specifies whether the external NTP server is the primary time source for correcting and adjusting the cluster time. The responses from this source will be used unless its time is outside the accepted selection range.

The default setting is false.

You use this parameter when a high quality radio (or GPS) based time server is being used with a set of non-radio based backup time servers.

Examples

The following example associates the cluster with an NTP server named ntp1.example.com.
cluster time-service ntp server delete

Delete a NTP Server

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**
The `cluster time-service ntp server delete` command removes the association between the cluster and an external network time server that uses the Network Time Protocol (NTP).

**Parameters**
- `-server <text>` - NTP Server Host Name, IPv4 or IPv6 Address
  This specifies the host name or IP address of an existing external NTP server that the cluster will disassociate from.

**Examples**
The following example disassociates an NTP server named ntp2.example.com from the cluster:

```
cluster1::> cluster time-service ntp server delete -server ntp2.example.com
```

cluster time-service ntp server modify

Modify NTP Server Options

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**
The `cluster time-service ntp server modify` command modifies the configuration of an existing external network time server that uses the Network Time Protocol (NTP) for time correction and adjustment.

**Parameters**
- `-server <text>` - NTP Server Host Name, IPv4 or IPv6 Address
  This specifies the host name or IP address of an existing external NTP server that is to be modified.
- `[version {3|4|auto}]` - NTP Version for Server (default: auto)
  This optionally specifies the NTP protocol version that should be used for communicating with the external NTP server. If the external NTP server does not support the specified protocol version, time exchange cannot take place.
  The supported values for this parameter include the following:
  - `3` - Use NTP protocol version 3, which is based on Internet Standard Request For Comments (RFC) #1305.
  - `4` - Use NTP protocol version 4, which is based on Internet Standard RFC #5905.
  - `auto` - Have Data ONTAP select the NTP protocol version.
  The default setting is auto.
- `[is-preferred {true|false}]` - Is Preferred NTP Server (default: false) (privilege: advanced)
  This optionally specifies whether the external NTP server is the primary time source for correcting and adjusting the cluster time. The responses from this source will be used unless its time is outside the accepted selection range
The default setting is \texttt{false}.

You use this parameter when a high quality radio (or GPS) based time server is being used with a set of non-radio based backup time servers.

This parameter is available only at the advanced privilege level and higher.

\begin{example}
\textbf{Examples}

The following example modifies the NTP version of an NTP server named ntp1.example.com. The NTP version is changed to 4.

\begin{verbatim}
cluster1::> cluster time-service ntp server modify -server ntp1.example.com -version 4
\end{verbatim}
\end{example}

\textbf{cluster time-service ntp server reset}

Reset NTP server list to a default selection

\textbf{Availability:} This command is available to \texttt{cluster} administrators at the \textit{advanced} privilege level.

\textbf{Description}

The \texttt{cluster time-service ntp server reset} command replaces the current configuration with one of the selected configurations.

If none or more than one time service configuration is selected, the command will fail.

\textbf{Parameters}

\begin{verbatim}
[-use-public \{true|false\}] - Reset Server List to Public Identified Defaults (default: false)
\end{verbatim}

When set to true, this specifies that the public NTP server list used by Data ONTAP should replace the current configuration.

The default setting is \texttt{false}.

\begin{example}
\textbf{Examples}

The following example replaces the current time service configuration with the default public NTP server list that is used by Data ONTAP.

\begin{verbatim}
cluster1::> cluster time-service ntp server reset -use-public true
\end{verbatim}
\end{example}

\textbf{cluster time-service ntp server show}

Display a list of NTP Servers

\textbf{Availability:} This command is available to \texttt{cluster} administrators at the \textit{admin} privilege level.

\textbf{Description}

The \texttt{cluster time-service ntp server show} command displays the association between the cluster and external network time servers that use the Network Time Protocol (NTP).

\textbf{Parameters}

\begin{verbatim}
[{-fields <fieldname>,...}]
\end{verbatim}

If you specify the \texttt{-fields <fieldname>,...} parameter, the command only displays the fields that you specify. For example: \texttt{-fields server,version}. 

cluster time-service commands
[-instance ]
If the -instance parameter is specified, the command displays all the available field information.

[-server <text>] - NTP Server Host Name, IPv4 or IPv6 Address
If this parameter is specified, the command displays the external NTP servers that match the specified server name or IP address.

[-version {3|4|auto}] - NTP Version for Server (default: auto)
If this parameter is specified, the command displays the external NTP servers that use the specified NTP version.

[-is-preferred {true|false}] - Is Preferred NTP Server (default: false) (privilege: advanced)
If this parameter is specified, the command displays the external NTP server or servers that match the specified preferred server status.

[-is-public {true|false}] - Is Public NTP Server Default (privilege: advanced)
If this parameter is specified, the command displays the information for the external NTP servers that are either on the NTP server list defined by Data ONTAP (`true`) or not on the list (`false`).

Examples
The following example displays information about all external NTP time servers that are associated with the cluster:

```
cluster1::> cluster time-service ntp server show
Server               Version
--------------------  -----------
ntp1.example.com     auto
ntp2.example.com     auto
```

Event Commands

Manage system events

The event commands enable you to work with system events and set up notifications.

**event catalog commands**

View the event catalog.

**event catalog show**

Display event definitions

**Availability**: This command is available to cluster administrators at the admin privilege level.

**Description**
The `event catalog show` command displays information about events in the catalog. By default, this command displays the following information:

- Message name of the event
- Severity of the event
- SNMP trap type of the event
To display detailed information about a specific event, run the command with the **-message-name** parameter, and specify the name of the event. The detailed view adds the following information:

- Full description of the event
- Action to be taken to address the event
- Event's deprecation status

You can specify additional parameters to limit output to the information that matches those parameters. For example, to display information only about events with an event name that begins with *raid*, enter the command with the **-message-name raid* parameter. The parameter value can either be a specific text string or a wildcard pattern.

Alternatively, an event filter can also be specified to limit the output events.

**Parameters**

```
{ [-fields <fieldname>, ... ]
  If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

  [-instance ]}
  If you specify the -instance parameter, the command displays detailed information about all fields.

  [-message-name <Message Name>] - Message Name
  Selects the events that match this parameter value.

  [-filter-name <text>] - Filter Name
  Selects the events that match this parameter value. The parameter value indicates an existing filter name that, when applied permits the inclusion of the listed events.

  [-severity {EMERGENCY|ALERT|ERROR|NOTICE|INFORMATIONAL|DEBUG}] - Severity
  Selects the events that match this parameter value.

  [-description <text>] - Description
  Selects the events that match this parameter value.

  [-action <text>] - Corrective Action
  Selects the events that match this parameter value.

  [-snmp-trap-type {Standard|Built-in|Severity-based}] - SNMP Trap Type
  Selects the events that match this parameter value. The parameter value describes the type of SNMP trap associated with the event. The value can be one of the following: Standard trap type events are those defined in the RFCs. Built-in trap types are those that are NetApp Enterprise traps specific to events. The remaining events are considered to have Severity-based SNMP trap types.

  [-deprecated {true|false}] - Is Deprecated
  Selects the events that match this parameter value. The parameter value indicates whether the event is deprecated or not.

  **Note:** Deprecated events may be removed in a future release of Data ONTAP.
```

### Examples

The following example displays the event catalog:

```
cluster1::> event filter show -filter-name filter1
Filter Name    Rule    Rule   Message Name    SNMP Trap Type    Severity
--------------- -------- --------- ------------------ --------------- --------
filter1        1       include  zap.*         *               *
```
2 entries were displayed.

cluster1::> event catalog show -filter-name filter1
Message                          Severity         SNMP Trap Type
-------------------------------- ---------------- -----------------
zapi.killed                      NOTICE           Severity-based
zapi.method.notfound             NOTICE           Severity-based
zapi.sf.up.ready                 INFORMATIONAL  Severity-based

22 entries were displayed.

cluster1::> event catalog show -instance

... ...
Message Name: Nblade.cifsEncSessAccessDenied
  Severity: ERROR
  Description: This message occurs when a client not capable of SMB encryption tries to
  establish a CIFS session that requires SMB encryption.
  Corrective Action: Either ensure that the client is capable of SMB encryption or disable SMB
  encryption on the Vserver.
  SNMP Trap Type: Severity-based
  Is Deprecated: false

Message Name: Nblade.cifsEncShrAccessDenied
  Severity: ERROR
  Description: This message occurs when a client not capable of SMB encryption tries to
  connect to a CIFS share that requires SMB encryption.
  Corrective Action: Either ensure that the client is capable of SMB encryption or disable SMB
  encryption on the CIFS share.
  SNMP Trap Type: Severity-based
  Is Deprecated: false

event config commands

Configure the mail server settings used for notifications

event config modify

Modify log configuration parameters

Availability: This command is available to cluster administrators at the admin privilege level.

Description
Use the event config modify command to configure event notification and logging for the cluster.

Parameters

[-mail-from <mail address>] - Mail From
Use this parameter to configure the email address from which email notifications will be sent. You can configure the cluster to send email notifications when specific events occur. Use the event route add-destinations and event destination create commands to configure email destinations for events.

[-mail-server <text>] - Mail Server (SMTP)
Use this parameter to configure the name or IP address of the SMTP server used by the cluster when sending email notification of events.

[-suppression {on|off}] - Event Throttling/Suppression (privilege: advanced)
Use this parameter to configure whether event suppression algorithms are enabled ("on") or disabled ("off"). The event processing system implements several algorithms to throttle events. The documentation for event show-suppression command describes the suppression algorithms in detail.

   Note: The suppression parameter can disable both autosuppression and duplicate suppression, but timer suppression cannot be disabled.

[-console {on|off}] - Console Logging (privilege: advanced)
Use this parameter to configure whether events are displayed on the console port ("on") or not displayed("off").

[-proxy-url <text>] - HTTP/HTTPS Proxy URL
If your organization uses a proxy, use this parameter to specify an HTTP or HTTPS proxy for rest-api type EMS notification destinations. The URL must start with an http:// prefix. HTTPS connections to a proxy are not supported. To specify a URL that contains a question mark, press ESC followed by the "?".

[-proxy-user <text>] - User Name for HTTP/HTTPS Proxy
If authentication is required, use this parameter to specify the user name for the HTTP or HTTPS proxy server specified by the -proxy-url parameter. Use the event config set-proxy-password command to set the password used for this user name.

Examples

The following command sets the "Mail From" address for event notifications to "admin@example.com" and the "Mail Server" to "mail.example.com":

   cluster1::> event config modify -mailfrom admin@example.com -mailserver mail.example.com

The following command configures a proxy that requires authentication:
cluster1::> event config modify -proxy-url http://proxy.example.com:8080 -proxy-user-name admin
cluster1::> event config set-proxy-password

Enter the password:
Confirm the password:

The following example turns on event suppression and console logging:

cluster1::> event config modify -suppression on -console on

- event destination create on page 81
- event log show on page 100
- event config set-proxy-password on page 80

**event config set-proxy-password**

Modify password for proxy server

**Availability:** This command is available to **cluster** administrators at the **admin** privilege level.

**Description**

Use the `event config set-proxy-password` command to set the password for authenticated access to an HTTP or HTTPS proxy being used for EMS notifications. This password is used with the user name you specify using the `event config modify -proxy-user` command to send EMS messages to REST API destinations via the proxy you specify using the `event config modify -proxy-url` command. If you enter the command without parameters, the command prompts you for a password and for a confirmation of that password. Enter the same password at both prompts. The password is not displayed.

**Examples**

The following example shows successful execution of this command:

```
cluster1::> event config set-proxy-password
Enter the password:
Confirm the password:
```

**event config show**

Display log configuration parameters

**Availability:** This command is available to **cluster** administrators at the **admin** privilege level.

**Description**

The `event config show` command displays information about the configuration of event notification and event logging for the cluster.

"Mail From" is the email address that the event notification system uses as the "From" address for email notifications.

"Mail Server" is the name or IP address of the SMTP server that the event notification system uses to send email notification of events.

"Proxy URL" is the HTTP or HTTPS proxy server URL used by rest-api type EMS notification destinations if your organization uses a proxy.

"Proxy User Name" is the user name for the HTTP or HTTPS proxy server if authentication is required.
"Suppression" indicates whether event suppression algorithms are enabled ("on") or disabled ("off"). The event processing system implements several algorithms to throttle events. See `event show-suppression` command for suppression algorithm details.

**Note:** The suppression parameter can disable both autosuppression and duplicate suppression, but not timer suppression.

"Console" indicates whether events are displayed on the console port ("on") or not displayed("off").

**Examples**

The following example displays the configuration of event notification for the cluster:

```
cluster1::> event config show
Mail From: admin@example.com
Mail Server: mail.example.com
Proxy URL: -
Proxy User Name: -
```

The following example displays the configuration of event notification with HTTP or HTTPS proxy:

```
cluster1::> event config show
Mail From: admin@example.com
Mail Server: mail.example.com
Proxy URL: http://proxy.example.com:3128
Proxy User Name: admin
```

At the diagnostic level, the output displays the following information:

```
cluster1::*> event config show
Mail From: admin@example.com
Mail Server: mail.example.com
Suppression: on
Console: on
Max Target Log Size: 5242880
Max Filter Count: 50
Max Filter Rule Count: 128
Max Destination Count: 20
Max Notification Count: 20
Filter Exempt from Suppression: no_info_debug_events
Duplicate Suppression Duration (secs): 120
Log Rotation Size (bytes): 40MB
```

event destination commands

(DEPRECATED)-Manage route destinations, for example e-mail or snmp

**event destination create**

(DEPRECATED)-Create an event destination

**Availability:** This command is available to `cluster` administrators at the `admin` privilege level.

**Description**

**Note:** This command has been deprecated. It may be removed from a future release of Data ONTAP. Instead, use the "event notification destination" command set.

The `event destination create` command creates a new event destination. An event destination is a list of addresses that receive event notifications. These addresses can be e-mail addresses, SNMP trap hosts, and syslog servers. Event destinations are used by event routes. Event routes describe which events generate notifications, and event destinations describe where to send those notifications.
When you create a destination, you can add e-mail addresses, SNMP trap hosts, and syslog hosts to the definition of the destination. Once the destination is fully defined, use the `event route add-destinations` command to associate the destination with event routes so that notifications of those events are sent to the recipients in the destination.

To see the current list of all destinations and their recipients, use the `event destination show` command.

There are several default destinations provided for your use.

- **allevents** - A useful destination for all system events, though no events are routed to this destination by default.
- **asup** - Events routed to this destination trigger AutoSupport(tm). Only use this destination to send notifications to technical support. See `system node autosupport` for more information.
- **critica** - A useful destination for critical events though no events are routed to this destination by default.
- **pager** - A useful destination for all events that are urgent enough to page a system administrator, though no events are routed to this destination by default.
- **traphost** - The default destination for all SNMP traps. You can also use the `system snmp traphost add` command to add SNMP recipients to the traphost default destination.

To add recipients to the default destinations, use the `event destination modify` command.

You should not create a destination that sends events to more than one type of recipient. Use separate destinations for e-mail, SNMP, and syslog activity. Also, use the traphost default destination for all SNMP activity. You must not create any other destination that sends traps to SNMP trap hosts. The traphost default destination is not required to be added to any event route.

**Parameters**

- **-name <text>** - Name
  
  This mandatory parameter specifies name of the event destination to create.

- **-mail <mail address>, ...** - Mail Destination
  
  Use this parameter to specify one or more e-mail addresses to which event notifications will be sent. For events to properly generate e-mail notifications, the event system must also be configured with an address and mail server from which to send mail. See `event config modify` for more information.

- **-snmp <Remote IP>, ...** - SNMP Destination
  
  To send traps to SNMP trap hosts, use this parameter with the host names or IP addresses of those trap hosts.

- **-syslog <Remote IP>, ...** - Syslog Destination
  
  Use this parameter with the host names or IP addresses of any remote syslog daemons to which syslog entries will be sent.

- **-syslog-facility <Syslog Facility>** - Syslog Facility
  
  This parameter optionally specifies a syslog facility with which the syslog is sent. Possible values for this parameter are default, local0, local1, local2, local3, local4, local5, local6, and local7. If you specify the default syslog facility, syslogs are tagged LOG_KERN or LOG_USER.

- **-snmp-community <text>** - SNMP Trap Community
  
  To specify an SNMP trap community, use this parameter with that string.

- **-hide-parameters {true|false}** - Hide Parameter Values?
  
  Use this parameter with the value "true" to hide event parameters by removing them from event notifications. This is useful to prevent sensitive information from being sent over non-secure channels.

**Examples**

The following example creates an event destination named support.email that e-mails events to the addresses supportmgr@example.com, techsupport@example.com, and oncall@example.com.

event destination modify on page 84

**event destination delete**

(DEPRECATED)-Delete an event destination

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**

Note: This command has been deprecated. It may be removed from a future release of Data ONTAP. Instead, use the "event notification destination" command set.

The event destination delete command removes a specified destination from the list of valid destinations. An event destination is a list of addresses that receive event notifications. These addresses can be e-mail addresses, SNMP trap hosts, and syslog servers. Event destinations are used by event routes. Event routes describe which events generate notifications, and event destinations describe where to send those notifications.

Once you delete a destination, you will not be able to add that destination to any event route.

You will not be able to delete a destination if it is in use by any event routes. To remove a destination from all event routes, so that you can delete it, use the event route remove-destinations -messagename * -destination name command.

There are several default destinations that cannot be deleted:

- allevents - A useful destination for all system events, though no events are routed to this destination by default.
- asup - Events routed to this destination trigger AutoSupport(tm). Only use this destination to send notifications to technical support. See system node autosupport for more information.
- criticals - A useful destination for critical events though no events are routed to this destination by default.
- pager - A useful destination for all events that are urgent enough to page a system administrator, though no events are routed to this destination by default.
- traphost - The default destination for all SNMP traps. You can also use the system snmp traphost delete command to delete SNMP recipients from the traphost default destination.

To see the current list of all destinations, use the event destination show command. To add a new destination to the list, use the event destination create command.

**Parameters**

- **-name <text>** - Name

  This mandatory parameter specifies the event destination to delete.
Examples
The following example deletes an event destination named manager.pager:

```
cluster1::> event destination delete -name manager.pager
```

Related references
- `event route remove-destinations` on page 117

**event destination modify**

(DEPRECATED)-Modify an event destination

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**

**Note:** This command has been deprecated. It may be removed from a future release of Data ONTAP. Instead, use the "event notification destination" command set.

The `event destination modify` command changes the definition of an existing event destination. An event destination is a list of addresses that receive event notifications. These addresses can be e-mail addresses, SNMP traphosts, and syslog servers. Event destinations are used by event routes. Event routes describe which events generate notifications, and event destinations describe where to send those notifications.

Modifying a parameter writes over the existing value of the parameter. To extend a parameter, make sure to include the current value of that parameter. For instance, to add an e-mail address to a destination, include all of the current e-mail addresses assigned to that destination along with the new address. To see the current definition of a destination, use the `event destination show -name name` command.

You must not create a destination that sends events to more than one type of recipient. Use separate destinations for e-mail, SNMP, and syslog activity. Also, use the traphost default destination for all SNMP activity. You should not create any other destination that sends to SNMP traphosts. The traphost default destination is not required to be added to any event route.

**Parameters**

- `-name <text>` - Name
  This mandatory parameter specifies name of the event destination to modify.

- `[-mail <mail address>, ...]` - Mail Destination
  Use this parameter to specify one or more e-mail addresses to which event notifications will be sent. For events to properly generate e-mail notifications, the event system must also be configured with an address and mail server from which to send mail. See `event config modify` for more information.

- `[-snmp <Remote IP>, ...]` - SNMP Destination
  To send traps to SNMP trap hosts, use this parameter with the host names or IP addresses of those trap hosts.

- `[-syslog <Remote IP>, ...]` - Syslog Destination
  Use this parameter with the host names or IP addresses of any remote syslog daemons to which syslog entries will be sent.
[-syslog-facility <Syslog Facility>] - Syslog Facility

This parameter optionally specifies a syslog facility with which the syslog is sent. Possible values for this parameter are default, local0, local1, local2, local3, local4, local5, local6, and local7. If you specify the default syslog facility, syslogs are tagged LOG_KERN or LOG_USER.

[-snmp-community <text>] - SNMP Trap Community

To specify an SNMP trap community, use this parameter with that string.

[-hide-parameters (true|false)] - Hide Parameter Values?

Enter this parameter with the value "true" to hide event parameters by removing them from event notifications. This is useful to prevent sensitive information from being sent over non-secure channels. Enter it with the value "false" to turn off parameter hiding.

Examples

The following example modifies an event destination named snmp.hosts to send events to SNMP trap hosts named traphost1 and traphost2:

```
cluster1::> event destination modify -name snmp.hosts -snmp traphost1.example.com,traphost2.example.com
```

This example adds the e-mail address of a remote support facility to an existing list of e-mail recipients.

```
cluster1::> event destination show -name support
Name: support
Mail Destination: support.hq@company.com
SNMP Destination: -
Syslog Destination: -
Syslog Facility: -
SNMP Trap Community: -
Hide Parameter Values?: -
cluster1::> event destination modify -name support -mail support.hq@company.com,support.remote@company.com
cluster1::> event destination show -name support
Name: support
Mail Destination: support.hq@company.com, support.remote@company.com
SNMP Destination: -
Syslog Destination: -
Syslog Facility: -
SNMP Trap Community: -
Hide Parameter Values?: -
```

**event destination show**

(DEPRECATED)-Display event destinations

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**

**Note:** This command has been deprecated. It may be removed from a future release of Data ONTAP. Instead, use the "event notification destination" command set.
The `event destination show` command displays information about configured event destinations. An event destination is a list of addresses that receive event notifications. These addresses can be e-mail addresses, SNMP trap hosts, and syslog servers. Event destinations are used by event routes. Event routes describe which events generate notifications, and event destinations describe where to send those notifications.

Default destinations:

- **allevents** - A useful destination for all system events, though no events are routed to this destination by default.
- **asup** - Events routed to this destination trigger AutoSupport(tm). Only use this destination to send notifications to technical support. See `system node autosupport` for more information.
- **criticals** - A useful destination for critical events although no events are routed to this destination by default.
- **pager** - A useful destination for all events that are urgent enough to page a system administrator, though no events are routed to this destination by default.
- **traphost** - The default destination for all SNMP traps. You can also use the `system snmp traphost show` command to view SNMP recipients for the traphost default destination.

To add recipients to the default destination, use the `event destination modify` command.

**Note:** While you can use both host names and IP addresses with parameters, only IP addresses are stored. Unless all DNS and reverse-DNS operations complete successfully, IP addresses might appear in command output.

### Parameters

```
[-fields <fieldname>, ...]
```

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

```
[-facility]
```

Displays only the syslog destinations and syslog facilities.

```
[-instance]
```

If you specify the `-instance` parameter, the command displays detailed information about all fields.

```
[-name <text>] - Name
```

Selects the destinations that match this parameter value.

```
[-mail <mail address>, ...] - Mail Destination
```

Selects the destinations that match this parameter value.

```
[-snmp <Remote IP>, ...] - SNMP Destination
```

Selects the destinations that match this parameter value (SNMP trap hosts).

```
[-syslog <Remote IP>, ...] - Syslog Destination
```

Selects the destinations that match this parameter value (syslog event notification daemons).

```
[-syslog-facility <Syslog Facility>] - Syslog Facility
```

Selects the destinations that match this parameter value. Valid values are: `default, local0, local1, local2, local3, local4, local5, local6, and local7`.

```
[-snmp-community <text>] - SNMP Trap Community
```

Selects the destinations that match this parameter value.

```
[-hide-parameters {true|false}] - Hide Parameter Values?
```

Selects the destinations that match this parameter value (`true` selects destinations that do not receive full event parameters, `false` selects destinations that receive full event parameters). Event parameters may be hidden to prevent sensitive information from being sent over non-secure channels.
Examples

The following example displays information about all event destinations:

```
cluster1::> event destination show
```

**event filter commands**

Create, delete and view event filters.

**event filter copy**

Copy an event filter

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**

The event filter copy command copies an existing filter to a new filter. The new filter will be created with rules from the source filter. For more information, see the event filter create command.

**Parameters**

- `-filter-name <text>` - Filter Name
  
  Use this mandatory parameter to specify the name of the event filter to copy.

- `-new-filter-name <text>` - New Event Filter Name
  
  Use this mandatory parameter to specify the name of the new event filter to create and copy the rules.

**Examples**

The following example copies an existing event filter named emer-wafl-events to a new filter named filter1:

```
cluster1::> event filter copy
```

<table>
<thead>
<tr>
<th>Filter Name</th>
<th>Rule</th>
<th>Rule</th>
<th>Message Name</th>
<th>SNMP Trap Type</th>
<th>Severity</th>
</tr>
</thead>
</table>

event filter commands
Related references

*event filter create* on page 88

**event filter create**

Create a new event filter.

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**

The *event filter create* command creates a new event filter. An event filter is used to select the events of interest and is made up of one or more rules, each of which contains the following three fields:

- **name** - event (message) name.
- **severity** - event severity.
- **snmp-trap-type** - event SNMP trap type.
These fields are evaluated for a match using a logical "AND" operation: name AND severity AND SNMP trap type. Within a field, the specified values are evaluated with an implicit logical "OR" operation. So, if `-snmp-trap-type Standard, Built-in` is specified, then the event must match `Standard OR Built-in`. The wildcard matches all values for the field.

- **Type** - include or exclude. When an event matches an include rule, it will be included into the filter, whereas it will be excluded from the filter if it matches an exclude rule.

Rules are checked in the order they are listed for a filter, until a match is found. There is an implicit rule at the end that matches every event to be excluded. For more information, see the `event filter rule` command.

There are three system-defined event filters provided for your use:

- **default-trap-events** - This filter matches all ALERT and EMERGENCY events. It also matches all Standard, Built-in SNMP trap type events.
- **important-events** - This filter matches all ALERT and EMERGENCY events.
- **no-info-debug-events** - This filter matches all non-INFO and non-DEBUG messages (EMERGENCY, ALERT, ERROR and NOTICE).

The system-defined event filters cannot be modified or deleted.

**Parameters**

- `-filter-name <text>` - **Filter Name**
  
  Use this mandatory parameter to specify the name of the event filter to create. An event filter name is 2 to 64 characters long. Valid characters are the following ASCII characters: A-Z, a-z, 0-9, ".", and ".". The name must start and end with: A-Z, a-z, ".", or 0-9.

**Examples**

The following example creates an event filter named filter1:

```
cluster1::> event filter create -filter-name filter1
```

```
cluster1::> event filter show

<table>
<thead>
<tr>
<th>Filter Name</th>

**event filter delete**

Delete existing event filters

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**
The `event filter delete` command deletes an existing event filter, along with all its rules.

The system-defined event filters cannot be deleted.

For more information, see the `event filter create` command.

**Parameters**

- **`-filter-name <text>` - Filter Name**
  Use this mandatory parameter to specify the name of the event filter to delete.

**Examples**
The following example deletes an event filter named `filter1`:

```
cluster1::> event filter show
Filter Name       Rule      Message Name              SNMP Trap Type  Severity
Position Type
----------- -------- ------------------ --------------- --------
default-trap-events
1 include *     * EMERGENCY, ALERT
2 include *     * Standard, Built-in
3 exclude *     *
filter1
1 include wafl.* * EMERGENCY
2 exclude *
important-events
1 include *     * EMERGENCY, ALERT
2 include callhome.* * ERROR
3 exclude *
no-info-debug-events
1 include *     * EMERGENCY, ALERT, ERROR,
NOTICE
2 exclude *
8 entries were displayed.
cluster1::> event filter delete -filter-name filter1
cluster1::> event filter show
Filter Name       Rule      Message Name              SNMP Trap Type  Severity

**`event filter create` on page 88**

**event filter rename**

Rename an event filter

**Availability:** This command is available to `cluster` administrators at the `admin` privilege level.

**Description**
The `event filter rename` command is used to rename an existing event filter.

There are system-defined event filters provided for your use. The system-defined event filters cannot be modified or deleted.

For more information, see the `event filter create` command.

**Parameters**

- **`-filter-name <text>` - Filter Name**
  
  Use this mandatory parameter to specify the name of the event filter to rename.

- **`-new-filter-name <text>` - New Event Filter Name**
  
  Use this mandatory parameter to specify the new name the event filter should be renamed to.

**Examples**

The following example renames an existing filter named `filter1` as `emer-wafl-events`:

```
cluster1::> event filter show
Filter Name Rule Position Rule Type Message Name            SNMP Trap Type  Severity
----------- -------- ---------- --------- ---------------------- --------------- --------
default-trap-events
  1 include *      *          *         EMERGENCY, ALERT
  2 include *      Standard, Built-in
  3 exclude *      *          *          *
filter1
  1 include wafl.* *          *         EMERGENCY
  2 exclude *      *          *          *
important-events
  1 include *      *          EMERGENCY, ALERT
  2 include callhome.* *          ERROR
  3 exclude *      *          *          *
no-info-debug-events
  1 include *      *          EMERGENCY, ALERT, ERROR, NOTICE
  2 exclude *      *          *          *
10 entries were displayed.
cluster1::> event filter rename -filter-name filter1 -new-filter-name emer-wafl-events

*event filter create* on page 88

**event filter show**

Display the list of existing event filters.

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**

The *event filter show* command displays all the event filters which are configured. An event filter is used to select the events of interest and is made up of one or more rules, each of which contains the following three fields:

- **name** - event (message) name.
- **severity** - event severity.
- **snmp-trap-type** - event SNMP trap type.

These fields are evaluated for a match using a logical "AND" operation: name AND severity AND SNMP trap type. Within a field, the specified values are evaluated with an implicit logical "OR" operation. So, if *-snmp-trap-type Standard, Built-in* is specified, then the event must match Standard OR Built-in. The wildcard matches all values for the field.

- **Type** - include or exclude. When an event matches an include rule, it will be included into the filter, whereas it will be excluded from the filter if it matches an exclude rule.

Rules are checked in the order they are listed for a filter, until a match is found. There is an implicit rule at the end that matches every event to be excluded. For more information, see *event filter rule* command.

There are three system-defined event filters provided for your use:

- **default-trap-events** - This filter matches all ALERT and EMERGENCY events. It also matches all Standard, Built-in SNMP trap type events.
- **important-events** - This filter matches all ALERT and EMERGENCY events.
- **no-info-debug-events** - This filter matches all non-INFO and non-DEBUG messages (EMERGENCY, ALERT, ERROR and NOTICE).

The system-defined event filters cannot be modified or deleted.

**Parameters**

```
{ [ -fields <fieldname>, ...] }  
If you specify the "fields <fieldname>, ..." parameter, the command output also includes the specified field or fields. You can use "fields ?" to display the fields to specify.

[ -instance ]  
If you specify the "instance" parameter, the command displays detailed information about all fields.

[ -filter-name <text> ] - Filter Name  
Selects the event filters that match this parameter value.

[ -position <integer> ] - Rule Position  
Selects the event filters that match this parameter value.
```
[-type {include|exclude}] - Rule Type
Selects the event filters that match this parameter value. The rule types are as follows:
- include - Events matching this rule are included in the specified filter.
- exclude - Events matching this rule are excluded in the specified filter.

[-message-name <text>] - Message Name
Selects the event filters that match this parameter value.

[-severity <text>,...] - Severity
Selects the events that match this parameter value. Severity levels:
- EMERGENCY - Disruption.
- ALERT - Single point of failure.
- ERROR - Degradation.
- NOTICE - Information.
- INFORMATIONAL - Information.
- DEBUG - Debug information.
- * - Includes all severities.

[-snmp-trap-type <text>,...] - SNMP Trap Type
Selects the event filters that match this parameter value. The SNMP trap types are as follows:
- Standard - Traps defined in RFCs.
- Built-in - Enterprise traps specific to events.
- Severity-based - Traps specific to events that do not belong to the above two types.
- * - Includes all SNMP trap types.

Examples
The following example displays the event filters:

```
cluster1::> event filter show
Filter Name  Rule     Rule      Message Name           SNMP Trap Type  Severity
Position Type
----------------- -------- --------- ---------------------- --------------- --------
default-trap-events 1        include   *                      *               EMERGENCY, ALERT
2        include   *                      Standard, Built-in
3        exclude   *                      *               *
important-events 1        include   *                      *               EMERGENCY, ALERT
2        exclude   *                      *               *
no-info-debug-events 1        include   *                      *               EMERGENCY, ALERT, ERROR,
2        exclude   *                      *               *
NOTICE 2        exclude   *                      *               *
7 entries were displayed.
```

The following example displays the event filters queried on the SNMP trap type value "Standard":

```
cluster1::> event filter show -snmp-trap-type Standard
Filter Name  Rule     Rule      Message Name           SNMP Trap Type  Severity
Position Type
----------------- -------- --------- ---------------------- --------------- --------
```
The following example displays the event filters with one or more rules that have no condition on the SNMP trap type. Note that the wildcard character has to be specified in double-quotes. Without double-quotes, output would be the same as not querying on the field.

<table>
<thead>
<tr>
<th>Filter Name</th>
<th>Rule</th>
<th>Message Name</th>
<th>SNMP Trap Type</th>
<th>Severity</th>

**event filter test**

Test an event filter

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**

The event **filter test** command is used to test an event filter. When specified with a message name, the command displays whether the message name is included or excluded from the filter. When specified without a message name, the command displays the number of events from the catalog that match the filter. For more information, see the **event filter create** command.

**Parameters**

- **-filter-name <text>** - Filter Name
  
  Use this mandatory parameter to specify the name of the event filter to test.

- **[-message-name <Message Name>]** - Message Name
  
  Use this optional parameter to specify the message name of the event to test against the filter.

**Examples**

The following example tests an event filter named err-waf1-no-scan-but-clone:
1        include   waf1.scan.clone.*      *               *  
2        exclude   waf1.scan.*          *               *  
3        include   waf1.*              *               EMERGENCY, ALERT, ERROR  
4        exclude   *                   *               *  
important-events  
1        include   *                   *               EMERGENCY, ALERT  
2        include   callhome.*          *               ERROR  
3        exclude   *                   *               *  
no-info-debug-events  
1        include   *                   *               EMERGENCY, ALERT, ERROR, NOTICE  

Filter Name Rule     Rule      Message Name           SNMP Trap Type  Severity  
Position Type  
----------- -------- --------- ---------------------- --------------- --------  
no-info-debug-events  
2        exclude   *                   *               *               *  
12 entries were displayed.

cluster1::> event filter test -filter-name err-waf1-no-scan-but-clone  
271 events will be included in the given filter.

cluster1::> event filter test -filter-name err-waf1-no-scan-but-clone -message-name  
waf1.scan.clone.split.cantLock  
The message-name "waf1.scan.clone.split.cantLock" is included in the given filter.

cluster1::> event filter test -filter-name err-waf1-no-scan-but-clone -message-name  
waf1.scan.layout.cantWrite  
The message-name "waf1.scan.layout.cantWrite" is excluded from the given filter.

  event filter create on page 88

event filter rule commands

Create and delete rules for a filter.

event filter rule add

Add a rule for an event filter

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The event filter rule add command adds a new rule to an existing event filter. See event filter create for more information on event filters and how to create a new event filter.

Parameters
  
  filter-name <text> - Filter Name

  Use this mandatory parameter to specify the name of the event filter to add the rule. Rules cannot be added to system-defined event filters.

  [-position <integer>] - Rule Position

  Use this optional parameter to specify the position of the rule in the event filter. It should be in the range (1..n-1), where 'n' is the position of the last rule, which is an implicit rule. Rules are checked in the order they are listed for a filter, until a match is found.

  type {include|exclude} - Rule Type

  Use this mandatory parameter to specify the type of the rule which determines whether to include or exclude the events that match this rule.

  [-message-name <text>] - Message Name

  Use this parameter to specify the message name of the event to include or exclude from the filter.
[-severity <text>,...] - Severity
Use this parameter to specify the list of severity values to match against the events. Enter multiple severities separated by a comma. To enter all severities, the wild card (*) can be used. The wild card cannot be specified with other severities. The default value is *.

[-snmp-trap-type <text>,...] - SNMP Trap Type
Use this parameter to specify the list of the SNMP trap type values to match against the events. Enter multiple SNMP trap types separated by comma. To enter all SNMP trap types, the wild card (*) can be used. The wild card cannot be specified with other SNMP trap types. The default value is *.

Examples
The following example adds a rule to an existing event filter "emer-and-wafl": All events with severity EMERGENCY and message name starting with "wafl.*" are included in the filter. Not specifying the SNMP trap type implies a default value of ".*

```
cluster1::> event filter rule add -filter-name emer-and-wafl -type include -message-name wafl.* -severity EMERGENCY
```

```
cluster1::> event filter show
```

<table>
<thead>
<tr>
<th>Filter Name</th>
<th>Rule</th>
<th>Rule Type</th>
<th>Message Name</th>
<th>SNMP Trap Type</th>
<th>Severity</th>
</tr>
</thead>
<tbody>
<tr>
<td>default-trap-events</td>
<td>include</td>
<td>+</td>

<tr>
<td>no-info-debug-events</td>
<td>include</td>
<td>+</td>
<td>EMERGENCY, ALERT, ERROR, NOTICE</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>exclude</td>
<td>+</td>
<td>*</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

```
10 entries were displayed.
```

The following example adds a rule to the event filter "emer-and-wafl" at position 1: All events with severity ALERT and message name starting with "wafl.scan.*" are included in the filter.

```
cluster1::> event filter rule add -filter-name emer-and-wafl -type include -message-name wafl.scan.* -severity ALERT -position 1
```

```
cluster1::> event filter show
```

*event filter create* on page 88

**event filter rule delete**

Delete a rule for an event filter

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**

The *event filter rule delete* command deletes a rule from an event filter. The position of all the rules following the deleted rule is updated to maintain a contiguous sequence. Use *event filter show* command to view the filters and the rules associated with them.

**Parameters**

*filter-name <text>* - Filter Name

Use this mandatory parameter to specify the name of the event filter from which you want to delete the rule.

Rules cannot be deleted from system-defined filters.

*position <integer>* - Rule Position

Use this mandatory parameter to specify the position of the rule to delete from the filter. It should be in the range (1..n-1), where 'n' is the position of the last rule, which is an implicit rule.

**Examples**

The following example deletes a rule at position 2 from an existing event filter "emer-and-wafl":

```
cluster1::> event filter rule delete -filter-name emer-and-wafl -position 2
```

12 entries were displayed.
### Related references

*event filter show* on page 92

### event filter rule reorder

Modify the index of a rule for an event filter

**Availability:** This command is available to cluster administrators at the *admin* privilege level.

**Description**

The *event filter rule reorder* command moves a rule to a new position in an existing event filter. Use *event filter show* command to display all the event filters and the rules associated with them.

**Parameters**

- `-filter-name <text>` - *Filter Name*

  Use this mandatory parameter to specify the name of the event filter from which you want to change the position of the rule. Rules from system-defined event filters cannot be modified.
- **position <integer>** - Rule Position

Use this mandatory parameter to specify the position of the rule you want to change. It should be in the range (1..n-1), where 'n' is the position of the last rule, which is an implicit rule.

- **to-position <integer>** - New Rule Position

Use this mandatory parameter to specify the new position to move the rule. It should be in the range (1..n-1), where 'n' is the position of the last rule, which is an implicit rule.

**Examples**

The following example changes the position of a rule from 1 to 2 from an existing event filter "emer-and-wafl":

```
cluster1::> event filter rule reorder -filter-name emer-and-wafl -position 1 -to-position 2

cluster1::> event filter show
```

**Related references**

*event filter show* on page 92
event log commands

Display the list of event occurrences

event log show

Display latest log events

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The event log show command displays the contents of the event log, which lists significant occurrences within the cluster. Use the event catalog show command to display information about events that can occur.

By default, the command displays EMERGENCY, ALERT and ERROR severity level events with the following information, with the most recent events listed first:

• The time at which the event occurred
• The node on which the event occurred
• The severity of the event
• The event’s message

To display detailed information about events, use one or more of the optional parameters that affect how the command output is displayed and the amount of detail that is included. For example, to display all detailed event information, use the -detail parameter.

To display NOTICE, INFORMATIONAL or DEBUG severity level events, use the -severity parameter.

Parameters

[-fields <fieldname>, ...]
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use `--fields` to display the fields to specify.

[-detail]
Displays additional event information such as the sequence number of the event.

[-detailtime]
Displays detailed event information in reverse chronological order.

[-instance]
If you specify the -instance parameter, the command displays detailed information about all fields.

[-node (<nodename>|local)] - Node
Displays a list of events for the node you specify. Use this parameter with the -seqnum parameter to display detailed information.

[-seqnum <Sequence Number>] - Sequence#
Selects the events that match this parameter value. Use with the -node parameter to display detailed information.

[-time <MM/DD/YYYY HH:MM:SS>] - Time
Selects the events that match this parameter value. Use the format: MM/DD/YYYY HH:MM:SS [+-HH:MM]. You can specify a time range by using the ".." operator between two time statements.
show -time "08/13/2010 05:55:00"..'08/13/2010 06:10:00"

Comparative time values are relative to "now". For example, to display only events that occurred within the last minute:

show -time >1m

[-severity {EMERGENCY|ALERT|ERROR|NOTICE|INFORMATIONAL|DEBUG}] - Severity
Selects the events that match this parameter value. Severity levels are as follows:

- EMERGENCY - Disruption.
- ALERT - Single point of failure.
- ERROR - Degradation.
- NOTICE - Information.
- INFORMATIONAL - Information.
- DEBUG - Debug information.

To display all events, including ones with severity levels of NOTICE, INFORMATIONAL and DEBUG, specify severity as follows:

show -severity <=DEBUG

[-ems-severity {NODE_FAULT|SVC_FAULT|NODE_ERROR|SVC_ERROR|WARNING|NOTICE|INFO|DEBUG|VAR}] - EMS Severity (privilege: advanced)
Selects the events that match this parameter value. Severity levels:

- NODE_FAULT - Data corruption has been detected or the node is unable to provide client service
- SVC_FAULT - A temporary loss of service, typically a transient software fault, has been detected
- NODE_ERROR - A hardware error that is not immediately fatal has been detected
- SVC_ERROR - A software error that is not immediately fatal has been detected
- WARNING - A high-priority message that does not indicate a fault
- NOTICE - A normal-priority message that does not indicate a fault
- INFO - A low-priority message that does not indicate a fault
- DEBUG - A debugging message
- VAR - A message with variable severity, selected at runtime.

[-source <text>] - Source
Selects the events that match this parameter value (typically a software module).

[-message-name <Message Name>] - Message Name
Selects the events that match this parameter value (string). Message names are descriptive, so filtering output by message name displays messages of a specific type.

[-event <text>] - Event
Selects the events that match this parameter value. The "event" field contains the full text of the event, including any parameters. For example, a wafl.vol.offline event will contain the name of the volume taken offline.
[-kernel-generation-num <integer>] - Kernel Generation Number (privilege: advanced)
Selects the events that match this parameter value. Only events that emanate from the kernel have kernel generation numbers.

[-kernel-sequence-num <integer>] - Kernel Sequence Number (privilege: advanced)
Selects the events that match this parameter value. Only events that emanate from the kernel have kernel sequence numbers.

[-action <text>] - Corrective Action
Selects the events that match this parameter value. The "action" field describes what steps, if any, you must take to remedy the situation.

[-description <text>] - Description
Selects the events that match this parameter value. The "description" field describes why the event was encountered and what it means.

[-filter-name <text>] - Filter Name
Selects the events that match this parameter value. Only events that were included by existing filters that match this value are displayed.

Examples
Selects the events that match this parameter value. Use the format: MM/DD/YYYY HH:MM:SS [+HH:MM]. You can specify a time range by using the ".." operator between two time statements.

```
show -time "08/13/2010 05:55:00".."08/13/2010 06:10:00"
```

Comparative time values are relative to "now". For example, to display only events that occurred within the last minute:

```
show -time >1m
```

Selects the events that match this parameter value. Severity levels are as follows:

- EMERGENCY - Disruption.
- ALERT - Single point of failure.
- ERROR - Degradation.
- NOTICE - Information.
- INFORMATIONAL - Information.
- DEBUG - Debug information.

To display all events, including ones with severity levels of NOTICE, INFORMATIONAL and DEBUG, specify severity as follows:

```
show -severity <=DEBUG
```

The following example displays the event log:

```
cluster1::> event log show
Time                Node             Severity      Event
------------------- ---------------- ------------- ------------------------
11/9/2015 13:54:19  node1            NOTICE        vifmgr.portup: A link up event was received on node node1, port e0a.
11/9/2015 13:54:19  node1            NOTICE        vifmgr.portup: A link up event was received on node node1, port e0d.
11/9/2015 13:54:19  node1            NOTICE        vifmgr.portup: A link up event was received on
```

Commands: Manual Page Reference
This example demonstrates how to use a range with the `-time` parameter to display all events that occurred during an extended time period. It displays all events that occurred between 1:45pm and 1:50pm on November 9, 2010.

```
cluster1::> event log show -time "11/9/2015 13:45:00".."11/9/2015 13:50:00"
```

The `-time` parameter also accepts values that are relative to "now". The following example displays events that occurred more than one hour ago:

```
cluster1::> event log show -time <1h
```

Severity levels sort in the order opposite to what you might expect. The following example displays all events that have a severity level of ERROR or more severe:

```
cluster1::> event log show -severity <ERROR
```

**event notification commands**

Create, modify, delete and view event notifications.

**event notification create**

Create an event notification

**Availability:** This command is available to cluster administrators at the `admin` privilege level.

**Description**

The `event notification create` command is used to create a new notification of a set of events defined by an event filter to one or more notification destinations.

**Parameters**

- `-filter-name <text>` - Filter Name

  Use this mandatory parameter to specify the name of the event filter. Events that are included in the event filter are forwarded to the destinations specified in the destinations parameter.

  The filter name passed to this command must be an existing filter. For more information, see the `event filter create` command.

- `-destinations <text>, ...` - List of Event Notification Destinations

  Use this mandatory parameter to specify the list of destinations to which the notification should be forwarded. Enter multiple destinations separated by a comma.
The destination passed to this command must be an existing destination. For more information, see the `event destination create` command.

### Examples
The following example creates an event notification for filter name "filter1" to destinations "email_dest, snmp-traphost and syslog_dest":

```bash
cluster1::> event notification destination show
```

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Params</th>
<th>Destination</th>
</tr>
</thead>
<tbody>
<tr>
<td>email_dest</td>
<td>email</td>
<td>false</td>
<td><a href="mailto:test@example.com">test@example.com</a></td>
</tr>
<tr>
<td>snmp-traphost</td>
<td>snmp</td>
<td>true</td>
<td>10.27.12.1 (from &quot;system snmp traphost&quot;)</td>
</tr>
<tr>
<td>syslog_dest</td>
<td>syslog</td>
<td>false</td>
<td>10.23.12.1</td>
</tr>
</tbody>
</table>

3 entries were displayed.

```bash
cluster1::> event filter show -filter-name filter1
```

<table>
<thead>
<tr>
<th>Filter Name</th>
<th>Rule</th>
<th>Message Name</th>
<th>SNMP Trap Type</th>
<th>Severity</th>
</tr>
</thead>
<tbody>
<tr>
<td>filter1</td>
<td>exclude</td>
<td>callhome.bad.ram</td>
<td>*</td>
<td>*</td>
</tr>
<tr>
<td></td>
<td>include</td>
<td>callhome.*</td>
<td>*</td>
<td>ALERT, ERROR</td>
</tr>
<tr>
<td></td>
<td>exclude</td>
<td>*</td>
<td>*</td>
<td>*</td>
</tr>
</tbody>
</table>

3 entries were displayed.

```bash
cluster1::> event notification create -filter-name filter1 -destinations email_dest,syslog_dest,snmp-traphost
```

```bash
cluster1::> event notification show
```

<table>
<thead>
<tr>
<th>ID</th>
<th>Filter Name</th>
<th>Destinations</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>filter1</td>
<td>email_dest, syslog_dest, snmp-traphost</td>
</tr>
</tbody>
</table>

### event notification delete
Delete event notifications

**Availability:** This command is available to `cluster` administrators at the `admin` privilege level.

**Description**
The `event notification delete` command deletes an existing event notification.

**Parameters**

- `-ID <integer>` - Event Notification ID

  Use this parameter to specify the ID of the notification to be deleted.

### Examples
The following example shows the deletion of event notification with ID 1:

```bash
cluster1::> event notification show
```

<table>
<thead>
<tr>
<th>ID</th>
<th>Filter Name</th>
<th>Destinations</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>filter1</td>
<td>email_dest, syslog_dest, snmp-traphost</td>
</tr>
</tbody>
</table>

Commands: Manual Page Reference
event notification modify

Modify event notifications

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The event notification modify command is used to modify an existing notification.

Parameters
-ID <integer> - Event Notification ID
Use this mandatory parameter to specify the ID of the notification to be modified.

[-filter-name <text>] - Event Filter Name
Use this parameter to specify the filter name to be modified.

[-destinations <text>, ...] - List of Event Notification Destinations
Use this parameter to specify the destinations to be modified. Enter multiple destinations separated by a comma.
Provide the complete set of destinations to be modified. Individual destination cannot be added or removed.

Examples
The following example shows the modification of event notification with ID 1:

```
cluster1::> event notification show
ID    Filter Name       Destinations
-----  ----------------  -----------------
1      filter1           email_dest, syslog_dest, snmp-traphost
cluster1::> event notification modify -ID 1 -destinations email_dest, syslog_dest
cluster1::> event notification show
ID    Filter Name       Destinations
-----  ----------------  -----------------
1      filter1           email_dest, syslog_dest
```

event notification show

Display event notifications

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The event notification show command is used to display the list of existing event notifications.
Parameters

{-fields <fieldname>,...}

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

{-instance}

If you specify the `-instance` parameter, the command displays detailed information about all fields.

-ID <integer> - Event Notification ID

Use this parameter to display the detailed information about the notification ID you specify.

{-filter-name <text> - Event Filter Name

Use this parameter to display event notifications that use the filter-name you specify.

{-destinations <text>,... - List of Event Notification Destinations

Use this parameter to display event notifications that use the destinations you specify.

Examples

The following example displays the event notification:

```
cluster1:>> event notification show
ID     Filter Name       Destinations
-----  ----------------  -----------------
    1     filter1           email_dest, syslog_dest, snmp-traphost
```

event notification destination commands

Create, modify, delete, test and view event notification destinations.

event notification destination create

Create an event notification destination

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The `event notification destination create` command creates a new event notification destination of either email or syslog type.

The following system-defined notification destination is configured for your use:

- snmp-traphost - This destination reflects the configuration in "system snmp traphost".

Parameters

-name <text> - Destination Name

Use this mandatory parameter to specify the name of the notification destination that is to be created. An event notification destination name must be 2 to 64 characters long. Valid characters are the following ASCII characters: A-Z, a-z, 0-9, ",", and ".". The name must start and end with: A-Z, a-z, or 0-9.

{ -email <mail address> - Email Destination

Use this parameter to specify the email address to which event notifications will be sent. For events to properly generate email notifications, the event system must also be configured with an address and mail server from which the mail will be sent. See `event config modify` command for more information.

| -syslog <text> - Syslog Destination

Use this parameter to specify syslog server host name or IP address to which syslog entries will be sent.
REST API Server URL

Use this parameter to specify REST API server URL to which event notifications will be sent. Enter the full URL, which must start either with an http:// or https:// prefix. To specify a URL that contains a question mark, press ESC followed by the "?".

Client Certificate Issuing CA

Use this parameter to specify the name of the certificate authority (CA) that signed the client certificate that will be sent in case mutual authentication with the REST API server is required. There can be multiple client certificates installed for the admin vserver in the cluster, and this parameter, along with the certificate-serial parameter, uniquely identifies which one. Use the security certificate show command to see the list of certificates installed in the cluster.

Client Certificate Serial Number

Use this parameter to specify the serial number of the client certificate that will be sent in case mutual authentication with the REST API server is required.

Examples

The following example shows the creation of a new event notification destination of type email called "StorageAdminEmail":

```bash
cluster1::> event notification destination create -name StorageAdminEmail -email StorageAdmin@example.com
cluster1::> event notification destination show
Name            Type        Destination
--------------  ----------  ---------------------
StorageAdminEmail  email       StorageAdmin@example.com
snmp-traphost   snmp        10.30.40.10 (from "system snmp traphost")
2 entries were displayed.
```

The following example shows the creation of a new event notification destination of type rest-api called "RestApi":

```bash
cluster1::> event notification destination create -name RestApi -rest-api-url https://rest.example.com/rest -certificate-authority cluster1-root-ca -certificate-serial 052213E60B7088
cluster1::> event notification destination show -name RestApi -instance

   Destination Name: RestApi
   Type of Destination: rest-api
   Destination Values: https://rest.example.com/rest
   Client Certificate Issuing CA: cluster1-root-ca
   Client Certificate Serial Number: 052213E60B7088
```

Related references

- security certificate show on page 397

**event notification destination delete**

Delete existing event destinations

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The event notification destination delete command deletes an event notification destination.

The following system-defined notification destination is configured for your use:
• snmp-traphost - This destination reflects the configuration in "system snmp traphost". To remove snmp-traphost addresses, use the \textit{system snmp traphost} command.

**Parameters**

\textbf{\texttt{-name <text>}} - Destination Name

Use this mandatory parameter to specify the name of an event destination to be removed.

**Examples**

The following shows the examples of deleting event notification destinations:

```
cluster1::> event notification destination show
Name          Type        Destination
-------------- ----------  ---------------------
StorageAdminEmail email      StorageAdmin@example.com
StorageAdminSyslog  syslog    example.com
snmp-traphost    snmp       10.30.40.10 (from "system snmp traphost")
3 entries were displayed.
cluster1::> event notification destination delete -name StorageAdminEmail
cluster1::> event notification destination show
Name          Type        Destination
-------------- ----------  ---------------------
StorageAdminSyslog  syslog    example.com
snmp-traphost    snmp       10.30.40.10 (from "system snmp traphost")
2 entries were displayed.
cluster1::> event notification destination delete -name Storage*
cluster1::> event notification destination show
Name          Type        Destination
-------------- ----------  ---------------------
snmp-traphost    snmp       10.30.40.10 (from "system snmp traphost")
1 entries were displayed.
```

**Related references**

\textit{system snmp traphost} on page 1196

**event notification destination modify**

Modify an event notification destination

**Availability:** This command is available to \textit{cluster} administrators at the \textit{admin} privilege level.

**Description**

The \textit{event notification destination modify} command modifies event notification destination.

The following system-defined notification destination is configured for your use:

• snmp-traphost - This destination reflects the configuration in "system snmp traphost". To modify traphost addresses, use the \textit{system snmp traphost} command.
Parameters

-name <text> - Destination Name

Use this mandatory parameter to specify the name of an event notification destination to be modified. The name of the destination must already exist.

{[-email <email address>]} - Email Destination

Use this parameter to specify a new value of email address to replace the current address in the event notification destination. The parameter is specified only when the event notification destination type is already "email". It is not allowed to specify the parameter for a destination that already has another type of destination address.

[-syslog <text>] - Syslog Destination

Use this parameter to specify a new syslog server host name or IP address to replace the current address of the event notification destination. The parameter is specified only when the event notification destination type is already "syslog". It is not allowed to specify the parameter for a destination that already has another type of destination address.

[-rest-api-url <text>] - REST API Server URL

Use this parameter to specify a new REST API server URL to replace the current address of the event notification destination. Enter the full URL, which must start either with an http:// or https:// prefix. To specify a URL that contains a question mark, press ESC followed by the "?". The parameter is specified only when the event notification destination type is already "rest-api". It is not allowed to specify the parameter for a destination that already has another type of destination address.

[-certificate-authority <text>] - Client Certificate Issuing CA

Use this parameter to specify a new value of the certificate authority (CA) to replace the current value in the event notification destination. There can be multiple client certificates installed for the admin vserver in the cluster, and this parameter, along with the certificate-serial parameter, uniquely identifies which one. Use the security certificate show command to see the list of certificates installed in the cluster.

[-certificate-serial <text>] - Client Certificate Serial Number

Use this parameter to specify a new serial number of the client certificate to replace the current value in the event notification destination.

Examples

The following example shows the modification of event notification destinations:

```
cluster1::> event notification destination show
Name             Type          Destination
----------------- ----------- ---------------------
StorageAdminEmail email      Storage@example.com
StorageAdminSyslog syslog     example.com
snmp-traphost     snmp        10.30.40.10 (from "system snmp traphost")
3 entries were displayed.

cluster1::> event notification destination modify -name StorageAdminEmail -email StorageAdmin@example.com

cluster1::> event notification destination show
Name             Type          Destination
----------------- ----------- ---------------------
StorageAdminEmail email      StorageAdmin@example.com
StorageAdminSyslog syslog     example.com
snmp-traphost     snmp        10.30.40.10 (from "system snmp traphost")
3 entries were displayed.
```
The following example shows how to clear the client certificate configuration when mutual authentication with the REST API server is no longer required:

```
cluster1::> event notification destination show -name RestApi -instance

Destination Name: RestApi
Type of Destination: rest-api
Destination Values: https://rest.example.com/rest
Client Certificate Issuing CA: cluster1-root-ca
Client Certificate Serial Number: 052213E60B7088

cluster-1::> event notification destination modify -name RestApi -certificate-authority - -
certificate-serial -

cluster-1::> event notification destination show -name RestApi -instance

Destination Name: RestApi
Type of Destination: rest-api
Destination Values: https://rest.example.com/rest
Client Certificate Issuing CA: -
Client Certificate Serial Number: -
```

**event notification destination show**

Display event notification destinations

**Availability:** This command is available to `cluster` administrators at the `admin` privilege level.

**Description**

The `event notification destination show` command displays event notification destinations.

**Parameters**

```
[-fields <fieldname>, ...]
```

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `'-fields ?'` to display the fields to specify.

```
[-instance]
```

If you specify the `-instance` parameter, the command displays detailed information about all fields.

```
[-name <text>] - Destination Name
```

Use this optional parameter to display information of an event notification destination that has the specified name.

```
[-type {snmp|email|syslog|rest-api}] - Type of Destination
```

Use this optional parameter to display information of event notification destinations that have the specified destination type.

```
[-destination <text>, ...] - Destination
```

Use this optional parameter to display information of event notification destinations that have the specified destination address. Enter multiple addresses separated by a comma.

```
[-server-ca-present {true|false}] - Server CA Certificates Present?
```

Use this optional parameter to display information of event notification destinations that have the specified server-ca-present value. This field indicates whether there are certificates of the server-ca type exist in the system. If not, event messages will not be sent to a rest-api type destination having an HTTPS URL.
Use this optional parameter to display information of event notification destinations that have the specified certificate authority name.

Use this optional parameter to display information of event notification destinations that have the specified certificate serial number.

Use this optional parameter to display information of event notification destinations that have the specified certificate-valid value. This field indicates whether the client certificate specified by the certificate-authority and certificate-serial fields is valid. If not, and if the REST API server requires client authentication, event messages will not be sent to the server.

Examples

The following shows examples of "event notification destination show":

```
cluster1::> event notification destination show
Name            Type        Destination
--------------  ----------  ---------------------
StorageAdminEmail email       StorageAdmin@example.com
StorageAdminSyslog syslog      example.com
snmp-traphost    smtp         10.30.40.10 (from "system snmp traphost")
RestApi         rest-api    https://rest.example.com/rest
4 entries were displayed.
cluster1::> event notification destination show -type snmp -instance
```

event notification history commands

The history directory

event notification history show

Display latest events sent to destination

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The event notification history show command displays a list of event messages that have been sent to a notification destination. Information displayed by the command for each event is identical to that of the event log show command. This command displays events sent to a notification destination while the event log show command displays all events that have been logged.

Parameters

{ [-fields <fieldname>, ...]  
  If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use -fields ? to display the fields to specify.
  | [-instance ]]  
  If you specify the -instance parameter, the command displays detailed information about all fields.}
-destination <text> - Destination
  Specifies the destination to which event messages have been sent to be displayed.

-[node {<nodename>|local}] - Node
  Displays a list of events for the node you specify. Use this parameter with the -seqnum parameter to display
detailed information.

-[seqnum <Sequence Number>] - Sequence#
  Selects the events that match this parameter value. Use with the -node parameter to display detailed
information.

-[time <MM/DD/YYYY HH:MM:SS>] - Time
  Selects the events that match this parameter value. Use the format: MM/DD/YYYY HH:MM:SS [+-
HH:MM]. You can specify a time range by using the ".." operator between two time statements.

-[severity {EMERGENCY|ALERT|ERROR|NOTICE|INFORMATIONAL|DEBUG}] - Severity
  Selects the events that match this parameter value. Severity levels are as follows:
  • EMERGENCY - Disruption.
  • ALERT - Single point of failure.
  • ERROR - Degradation.
  • NOTICE - Information.
  • INFORMATIONAL - Information.
  • DEBUG - Debug information.

-[message-name <Message Name>] - Message Name
  Selects the events that match this parameter value (string). Message names are descriptive, so filtering output
by message name displays messages of a specific type.

-[event <text>] - Event
  Selects the events that match this parameter value. This parameter is useful when entered with wildcards. The
"event" field contains the full text of the event, including any parameters. For example, the wafl.vol.offline
event displays the name of the volume that is taken offline.

Examples
The following example displays all the events which match "important-events" filter and forwarded to the "snmp-
traphost" destination:

```
cluster1::> event filter show
Filter Name Rule Position Type Message Name SNMP Trap Type Severity
---------- -------- --------- -------------- --------------- ---------
default-trap-events 1 include * * * EMERGENCY, ALERT
2 include * Standard, Built-in * *
3 exclude * * *
important-events 1 include * * EMERGENCY, ALERT
2 include callhome.* * ERROR
3 exclude * * *
no-info-debug-events 1 include * * EMERGENCY, ALERT, ERROR,
NOTICE 1 include * * EMERGENCY, ALERT, ERROR,
8 entries were displayed.
```

```
cluster1::> event notification destination show
Name Type Destination
---------- -------- ---------
```

112 Commands: Manual Page Reference
event mailhistory commands

(DEPRECATED)-Display the list of e-mailed events

event mailhistory delete

(DEPRECATED)-Delete an e-mail history record

**Availability:** This command is available to `cluster` administrators at the `admin` privilege level.

**Description**

**Note:** This command has been deprecated. It may be removed from a future major release of Data ONTAP. Instead, use the "event notification history" command set.

The event mailhistory delete command deletes a record from the e-mail history.

To delete a record, you must know which node contains the record, and the record's sequence number. Use the event mailhistory show command to view this information.

**Parameters**

- **-node** `<nodename>|local` - Node
  
  Use this parameter to specify the name of the node that contains the e-mail history record to delete.

- **-seqnum** `<Sequence Number>` - Sequence Number
  
  Use this parameter to specify the sequence number of the e-mail history record to delete.

**Examples**

The following example deletes all mail-history records on node1:

```
cluster1::> event mailhistory delete -node node1 -seqnum *
```

**Related references**

event mailhistory show on page 113

event mailhistory show

(DEPRECATED)-Display a list of e-mail history records

**Availability:** This command is available to `cluster` administrators at the `admin` privilege level.
Description

Note: This command has been deprecated. It may be removed from a future release of Data ONTAP. Instead, use the "event notification history" command set.

The event mailhistory show command displays a list of the event notifications that have been e-mailed. The command output depends on the parameters you specify with the command. By default, the command displays basic information about all notification e-mails that were sent.

To display detailed information about a specific mail-history record, run the command with the -seqnum parameter.

Parameters

{ [-fields <fieldname>, ...]  
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

| [-instance ]  
If you specify the -instance parameter, the command displays detailed information about all fields.

[-node [<nodename>|local]] - Node
Selects the mail-history records that match this parameter value.

[-seqnum <Sequence Number>] - Sequence Number
Selects the mail-history records that match this parameter value.

[-message-name <Message Name>] - Message Name
Selects the mail-history records that match this parameter value.

[-address <mail address>,...] - Mail Address
Selects the mail-history records that match this parameter value.

[-time <MM/DD/YYYY HH:MM:SS>] - Transmission Time
Selects the mail-history records that match this parameter value.

[-message <text>] - Alert Message
Selects the mail-history records that match this parameter value (text pattern).

[-previous-time <MM/DD/YYYY HH:MM:SS>] - Previous Transmission Time
Selects the mail-history records that match this parameter value.

[-num-drops-since-previous <integer>] - Number of Drops Since Previous Transmission
Selects the mail-history records that match this parameter value (number of event drops since last transmission).

Examples

The following example displays detailed information about the mail-history record with the sequence number 20520:

```
cluster1:/> event mailhistory show -seqnum 20520
  Sequence Number: 20520
  Message Name: waf1.vol.full
  Address: admin@example.com
  Time: 10/1/2008 14:06:24
  Node: node3
  Previous Time: 5/31/2007 00:33:22
  # Drops Since Prev: 0
  Mail Message: waf1.vol.full: file system on volume
  vol10@vserver:28558fe3-2462-11da-85ab
  -000423bacd20 is full
```
event route commands

(DEPRECATED)-Manage the mapping between events and destinations

event route add-destinations

(DEPRECATED)-Add destination(s) to an event definition

Availability: This command is available to cluster administrators at the admin privilege level.

Description

Note: This command has been deprecated. It may be removed from a future release of Data ONTAP. Instead, use the "event notification" command set.

The event route add-destinations command adds destinations to an event route. Any existing destinations assigned to the route are not removed.

The destinations you add must already exist. See the documentation for the event destination create command for information about creating destinations. To show all existing destinations and their attributes, use the event destination show command. To remove destinations from an event route, use the event route remove-destinations command.

You can use extended queries with such parameters as -severity and -snmp-support to specify multiple events that meet certain criteria. See examples below that show how to use extended queries.

Parameters

-message-name <Message Name> - Message Name
  Specify the message name of the event you are modifying. You can use wildcards to specify a family of events or type of event.

[-severity {EMERGENCY|ALERT|ERROR|NOTICE|INFORMATIONAL|DEBUG}] - Severity
  Use this optional parameter to specify a set of events that match this parameter value. You must use the -message-name parameter with wildcards to specify the family of events or type of events.

-destinations <Event Destination>, ... - Destinations
  Specify a comma-separated list of destinations to which notifications for the named event are sent. These destinations will be added to any existing destinations assigned to this event route.

Examples

The following example specifies that all RAID events go to the destinations named support.email, mgr.email, and sreng.pager:

```
cluster1::> event route add-destinations -message-name raid* -destinations support.email,mgr.email,sreng.pager
```

The following example specifies that all alert, and emergency events go to the destination named test_dest:

```
cluster1::> event route add-destinations -message-name * -severity <=ALERT -destinations test_dest
```

The following example specifies that all alert events that support a SNMP trap go to the destination named traphost. In this example, because the -snmp-support parameter is specified as part of extended queries, the -severity parameter must also be specified in the extended queries:
Related references

- **event destination create** on page 81
- **event destination show** on page 85
- **event route remove-destinations** on page 117

**event route modify**

(DEPRECATED)-Modify an event's destination, reporting threshold, or both

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**

**Note:** This command has been deprecated. It may be removed from a future release of Data ONTAP. Instead, use the "event notification" command set.

Use the **event route modify** command to modify an event's destination, frequency threshold, and time threshold. The event's destination must already exist; see the documentation for the **event destination create** command for information about creating destinations. The frequency threshold and time threshold prevent multiple event notifications in a brief period of time.

You can use extended queries with such parameters as **-severity** and **-snmp-support** to specify multiple events that meet certain criteria. See examples provided in the **event route add-destinations** command manpage that show how to use extended queries.

The frequency threshold specifies the number of times an event occurs before a repeat notification of the event is sent; for instance, a frequency threshold of 5 indicates that a notification is sent every fifth time an event occurs. The time threshold specifies the number of seconds between notifications for an event; for instance, a time threshold of 120 indicates that a notification is sent only if it has been two minutes or more since the last notification for that event was sent.

If both the frequency threshold and time threshold are set, a notification is sent if either threshold is met. For instance, if the frequency threshold is set to 5 and the time threshold is set to 120, and the event occurs more than five times within two minutes, a notification is sent. If both thresholds are set to 0 (zero) or empty ("-" or ""), there is no suppression of multiple event notifications.

**Parameters**

**-message-name <Message Name> - Message Name**

Specify the message name of the event you are modifying. You can use wildcards to specify a family of events or type of event.

**[-severity {EMERGENCY|ALERT|ERROR|NOTICE|INFORMATIONAL|DEBUG} - Severity**

Use this optional parameter to specify a set of events that match this parameter value. You must use the **-message-name** parameter with wildcards to specify the family of events or type of events.

**[-destinations <Event Destination>, ...] - Destinations**

Use this optional parameter to specify a comma-separated list of destinations to which notifications for the named event are sent. Using this parameter replaces the current list of destinations with the list of destinations you specify. To add or remove individual destinations from the current list, use **event route add-destinations** or **event route remove-destinations**.

**[-frequencythreshold <integer>] - Number of Drops Between Transmissions**

Specifies the number of event notifications that must occur within the **timethreshold** period before a repeat notification is sent.
[-timethreshold <integer>] - Dropping Interval (Seconds) Between Transmissions
    If multiple notifications of an event occur within this many seconds, only the first notification is sent. Multiple
    notifications will be sent during this time period only if the frequencythreshold quantity is exceeded.

Examples
The following example modifies all RAID events to send messages to a destination named "support.email", and specify
that multiple messages should only be sent if and event occurs more than five times within 60 seconds.

```
cluster1::> event route modify -messagename raid* -destinations support.email -frequencythreshold 5 -timethreshold 60
```

* event route add-destinations on page 115
* event route remove-destinations on page 117
* event destination create on page 81

**event route remove-destinations**

(DEPRECATED)-Remove destination(s) from an event definition

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**

* **Note:** This command has been deprecated. It may be removed from a future release of Data ONTAP. Instead, use the "event
  notification" command set.

The `event route remove-destinations` command can be used to remove existing destinations from an event route. This
command removes only the specified destinations from the route, leaving any other destinations assigned to that route.

The named destinations are not deleted, just removed from the specified event route. To delete a destination entirely, use the
`event destination delete` command. To show all existing destinations and their attributes, use the `event destination
show` command.

You can use extended queries with such parameters as `-severity` and `-snmp-support` to specify multiple events that meet
certain criteria. See examples provided in the `event route add-destinations` command manpage that show how to use
extended queries.

**Parameters**

* `-message-name <Message Name>` - Message Name
    Specify the message name of the event you are modifying. You can use wildcards to specify a family of events
    or type of event.

* `[-severity {EMERGENCY|ALERT|ERROR|NOTICE|INFORMATIONAL|DEBUG}]` - Severity
    Use this optional parameter to specify a set of events that match this parameter value. You must use the `-message-name`
    parameter with wildcards to specify the family of events or type of events.

* `-destinations <Event Destination>, ...` - Destinations
    Specify a comma-separated list of destinations to remove from the event's list of destinations.

Examples
The following example specifies that the destination named "mgr.email" should no longer receive notifications of RAID
events.
event route show

(DEPRECATED) Display event routes

Availability: This command is available to cluster administrators at the admin privilege level.

Description

Note: This command has been deprecated. It may be removed from a future release of Data ONTAP. Instead, use the "event catalog" command set.

This command displays information about event routes. Event routes describe which events generate notifications. A route specifies what to watch for, whom to notify, and what to do should a particular event occur. By default, the command displays the following information:

- Message name of the event
- Severity of the event
- Destinations for event notifications
- Frequency threshold for event notifications
- Time threshold for event notifications

To display detailed information about a specific event route, run the command with the -message-name parameter, and specify the name of the message. The detailed view adds the following information:

- Full description of the event
- Action to be taken to address the event

You can specify additional parameters to limit output to the information that matches those parameters. For example, to display information only about events with a message name that begins with "raid", run the command with the -message-name raid* parameter. You can enter either a specific text string or a wildcard pattern.

Parameters

[-fields <fieldname>, ...]

If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields?' to display the fields to specify.

[[-instance ]]

If you specify the -instance parameter, the command displays detailed information about all fields.

[-message-name <Message Name>] - Message Name

Selects the event routes that match this parameter value.

[-severity {EMERGENCY|ALERT|ERROR|NOTICE|INFORMATIONAL|DEBUG}] - Severity

Selects the event routes that match this parameter value. Valid values:

- EMERGENCY - Disruption
• ALERT - Single point of failure
• ERROR - Degradation
• NOTICE - Information
• INFORMATIONAL - Information
• DEBUG - Debug information

[-action <text>] - Corrective Action
Selects the events that match this parameter value. This parameter is most useful when entered with wildcards. The "action" field describes what steps, if any, you must take to remedy the situation.

[-description <text>] - Description
Selects the events that match this parameter value. This parameter is most useful when entered with wildcards. The "description" field describes why the event was encountered and what it means.

[-snmp-support {true|false}] - Supports SNMP trap
Selects the event routes that match this parameter value.

[-destinations <Event Destination>, ...] - Destinations
Selects the event routes that match this parameter value. A destination is a list of email addresses, SNMP clients, and syslogs.

[-frequencythreshold <integer>] - Number of Drops Between Transmissions
Selects the event routes that match this parameter value (number of events since previous notification).

[-timethreshold <integer>] - Dropping Interval (Seconds) Between Transmissions
Selects the event routes that match this parameter value.

Examples
The following example displays information about all event routes:

```
cluster1:/> event route show

event snmphistory commands
(DEPRECATED)-Display the list of SNMP-trap events
event snmphistory delete

(DEPRECATED)-Delete an SNMP trap history record

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**

**Note:** This command has been deprecated. It may be removed from a future release of Data ONTAP. Instead, use the "event notification history" command set.

The **event snmphistory delete** command deletes an SNMP trap-history record. To delete a record, you will need to know which node generated the event, and you will need to know the sequence number of that event in the trap-history.

Use the **event snmphistory show** command to display a list of trap-history records and their sequence numbers.

**Parameters**

- **-node \(<nodename>\) | local** - Node
  
  Use this parameter to specify the name of the node that contains the snmp history record to delete.

- **-seqnum \(<Sequence Number>\)** - Sequence Number
  
  Use this parameter to specify the sequence number of the SNMP trap-history record to delete.

**Examples**

The following example deletes all SNMP trap-history records on node1:

```
cluster1::> event snmphistory delete -node node1 -seqnum *
```

**Related references**

*event snmphistory show* on page 120

---

**event snmphistory show**

(DEPRECATED)-Display a list of SNMP trap history records

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**

**Note:** This command has been deprecated. It may be removed from a future release of Data ONTAP. Instead, use the "event notification history" command set.

The **event snmphistory show** command displays a list of event notifications that have been sent to SNMP traps. The command output depends on the parameters specified with the command. By default, the command displays general information about all trap-history records.

To display detailed information about a specific trap-history record, run the command with the `-seqnum` parameter.

**Parameters**

```
[-fields \(<fieldname>\),...]
```

If you specify the `-fields \(<fieldname>\),...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

```
[-instance]
```

If you specify the `-instance` parameter, the command displays detailed information about all fields.
[\text{-node}\ \{<\text{nodename}>|\text{local}\}\} - \text{Node}\n
Selects the trap-history records that match this parameter value (text pattern).

[\text{-seqnum} \{<\text{Sequence\ Number}>\} - \text{Sequence Number}\n
Selects the trap-history records that match this parameter value (sequence number).

[\text{-message-name} \{<\text{Message\ Name}>\} - \text{Message Name}\n
Selects the trap-history records that match this parameter value.

[\text{-address} \{<\text{text}>\}, ...] - \text{SNMP\ Client\ Address}\n
Selects the trap-history records that match this parameter value (IP address).

[\text{-time} \{<\text{MM/DD/YYYY\ HH:MM:SS}>\} - \text{Transmission\ Time}\n
Selects the trap-history records that match this parameter value.

[\text{-message} \{<\text{text}>\} - \text{Alert\ Message}\n
Selects the trap-history records that match this parameter value (text pattern).

[\text{-previous-time} \{<\text{MM/DD/YYYY\ HH:MM:SS}>\} - \text{Previous\ Transmission\ Time}\n
Selects the trap-history records that match this parameter value.

[\text{-num-drops-since-previous} \{<\text{integer}>\} - \text{Number\ of\ Drops\ Since\ Previous\ Transmission}\n
Selects the trap-history records that match this parameter value (number of event drops since last transmission).

\bf{Examples}\n
The following example displays information about all SNMP trap-history records:

```
cluster1::> event snmphistory show
Seq # Message Name          Address   Node  Time
----- --------------------- --------- ----- ------------------
12481 raid.mirror.restrict  10.0.2.20 node0 4/14/2008 15:11:04
12482 aggrcopy.dst.noMemory 10.0.2.20 node0 4/14/2008 14:52:54
12483 raid.mirror.restrict  10.0.2.21 node1 4/14/2008 14:41:04
```

\bf{event status commands}\n
Display the status of events, including occurrences and drops

\bf{event status show}\n
Display event status

\textbf{Availability:}\ This command is available to \textit{cluster} administrators at the \textit{admin} privilege level.

\textbf{Description}\n
The \textit{event status show} command summarizes information about occurrences of events. For detailed information about specific occurrences of events, use the \textit{event log show} command.

\textbf{Parameters}\n
\{\text{-fields} \{<\text{fieldname}>\}, ...\}\n
If you specify the \textit{-fields} \{<\text{fieldname}>\}, ... parameter, the command output also includes the specified field or fields. You can use \text{`-fields ?'} to display the fields to specify.

\{\text{-instance}\}\n
If you specify the \textit{-instance} parameter, the command displays detailed information about all fields.
[-node <nodename>|local]] - Node
Selects the event records that match this parameter value. Events are tracked on a node-by-node basis, rather than being rolled up cluster-wide.

[-message-name <Message Name>] - Message Name
Selects the event records that match this parameter value. The message name is a short descriptive string. Filtering output by message name displays messages of a specific type.

[-indications <integer>] - Number of Indications
Selects the event records that match this parameter value. This parameter is most useful when used with a range, such as using the range ">20" to display only events that have been posted more than 20 times.

[-drops <integer>] - Number of Drops
Selects the event records that match this parameter value.

[-last-time-occurred <MM/DD/YYYY HH:MM:SS>] - Last Indication Time
Selects the event records that match this parameter value.

[-last-time-dropped <MM/DD/YYYY HH:MM:SS>] - Last Suppressed Indication Time
Selects the event records that match this parameter value.

[-last-time-processed <MM/DD/YYYY HH:MM:SS>] - Last Processed Indication Time
Selects the event records that match this parameter value.

Selects the event records that match this parameter value.

[-last-hour-histogram <integer>, ...] - 60-minute Histogram (privilege: advanced)
Use this parameter with the -fields parameter to display the "last hour" histogram for each event type. The last hour histogram records the number of times each event occurred in the last hour. The histogram is divided into sixty buckets, and each bucket collects one minute's events. The buckets display with the most recent event first.

[-last-day-histogram <integer>, ...] - 24-hour Histogram (privilege: advanced)
Use this parameter with the -fields parameter to display the "last day" histogram for each event type. The last day histogram records the number of times each event occurred in the last day. The histogram is divided into 24 buckets, and each bucket collects one hour's events. The buckets display with the most recent event first.

[-last-week-histogram <integer>, ...] - 7-day Histogram (privilege: advanced)
Use this parameter with the -fields parameter to display the "last week" histogram for each event type. The last week histogram records the number of times each event occurred in the last week. The histogram is divided into 7 buckets, and each bucket collects one day's events. The buckets display with the most recent event first.

[-severity {NODE_FAULT|SVC_FAULT|NODE_ERROR|SVC_ERROR|WARNING|NOTICE|INFO|DEBUG|VAR}] - Severity
Selects events that have the event severity you specify. Severity levels sort with the most severe levels first.

Severity levels:

- NODE_FAULT - The node has detected data corruption, or is unable to provide client service.
- SVC_FAULT - The node has detected a temporary loss of service. Typically, this is caused by a transient software fault.
- NODE_ERROR - The node has detected a hardware error that is not immediately fatal.
- SVC_ERROR - The node has detected a software error that is not immediately fatal.
- WARNING - A high-priority message that does not indicate a fault.
• NOTICE - A normal-priority message that does not indicate a fault.
• INFO - A low-priority message that does not indicate a fault.
• DEBUG - A debugging message. These messages are typically suppressed.
• VAR - These messages have variable severity. Severity level for these messages is selected at runtime.

The examples below illustrate how to query on severity.

**Examples**

The following example displays recent event-occurrence status for node1:

```
cluster1::> event status show -node node1
Node Message                      Occurs Drops Last Time
----------------- ---------------------------- ------ ----- -------------------
node1             raid.spares.media_scrub.start 6      0     3/11/2010 15:59:00
node1             raid.uninitialized.parity.vol   3      0     3/11/2010 15:58:28
node1             raid.vol.state.online            3      0     3/11/2010 15:58:29
node1             reg.defaultCommit.set.timeTaken  1      0     3/11/2010 15:56:28
node1             scsitgt.ha.state.changed         2      0     3/11/2010 15:58:28
node1             ses.multipath.notSupported       2      0     3/11/2010 15:58:28
node1             shelf.config.mpha                1      0     3/11/2010 15:58:48
node1             sk.hog.runtime                    1      0     3/11/2010 15:58:28
node1             snmp.agent.msg.access.denied     1      0     3/11/2010 15:58:28
node1             snmp.link.up                      6      0     3/11/2010 15:58:28
node1             tar.csum.mismatch                 2      0     3/11/2010 15:58:28
node1             tar.extract.success               2      0     3/11/2010 15:58:28
node1             vifmgr.lifsuccessfullymoved       3      0     3/11/2010 15:58:46
node1             vifmgr.portdown                   5      0     3/11/2010 15:58:48
node1             vifmgr.portup                     5      0     3/11/2010 15:58:48
node1             vifmgr.startedsuccessfully        1      0     3/11/2010 15:58:43
```

The following example displays a summary of events which are warnings or more severe:

```
cluster1::> event status show -node node1 -severity <=warning -fields indications,drops,severity
node    message-name             indications drops severity
------- ------------------------ ----------- ----- --------
node1   api.output.invalidSchema 5463        840   WARNING
node1   callhome.dsk.config      1           0     WARNING
node1   callhome.sys.config      1           0     SVC_ERROR

Job Commands

Manage jobs and job schedules

The job commands enable you to manage jobs and schedules. A job is defined as any asynchronous operation.

job delete

Delete a job

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description

The job delete command deletes a job. Use the job show command to view a list of running jobs that can be deleted.

Parameters

- `-id <integer>` - Job ID
  The numeric ID of the job you want to delete. A job ID is a positive integer.

- `[-vserver <vserver name>]` - Owning Vserver
  Use this parameter to specify the name of the Vserver that owns the job.

Examples

The following example deletes the job that has ID 99:

```
cluster1::> job delete -id 99
```

Related references

- job show on page 126

job pause

Pause a job

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.
**Description**

The `job pause` command pauses a job. Use the `job resume` command to resume a paused job. Use the `job show` command to view a list of running jobs that can be paused.

**Parameters**

- `-id <integer>` - Job ID

  The numeric ID of the job you want to pause. A job ID is a positive integer.

- `[-vserver <vserver name>]` - Owning Vserver

  Use this parameter to specify the name of the Vserver that owns the job.

**Examples**

The following example pauses the job that has ID 183:

```
cluster1::> job pause -id 183
```

**Related references**

- `job resume` on page 125
- `job show` on page 126

---

**job resume**

Resume a job

**Availability**: This command is available to `cluster` and `Vserver` administrators at the `admin` privilege level.

**Description**

The `job resume` command resumes a job that was previously paused by using the `job pause` command. Use the `job show` command to view a list of paused jobs that can be resumed.

**Parameters**

- `-id <integer>` - Job ID

  The numeric ID of the paused job to be resumed. A job ID is a positive integer.

- `[-vserver <vserver name>]` - Owning Vserver

  Use this parameter to specify the name of the Vserver that owns the job.

**Examples**

The following example resumes the paused job that has ID 183:

```
cluster1::> job resume -id 183
```

**Related references**

- `job pause` on page 124
- `job show` on page 126
**job show**

Display a list of jobs

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

**Description**
The *job show* command displays information about jobs. By default, the command displays information about all current jobs.

To display detailed information about a specific job, run the command with the `-id` parameter.

You can specify additional parameters to select information that matches the values you specify for those parameters. For example, to display information only about jobs running on a specific node, run the command with the `-node` parameter.

**Parameters**

```
[[-fields <fieldname>, ...]
  If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified
  field or fields. You can use `-fields ?` to display the fields to specify.

  [-inprogress ]
  Displays the job ID, the job name, the owning Vserver, and the progress of the job.

  [-jobstate ]
  Displays information about each job's state, including the queue state, whether the job was restarted, and when
  the job has completely timed out.

  [-sched ]
  Displays the job ID, the job name, the owning Vserver, and the schedule on which the job runs.

  [-times ]
  Displays the job ID, the job name, the owning Vserver, the time when the job was last queued, the time when
  the job was last started, and the time when the job most recently ended.

  [-type ]
  Displays the job ID, the job name, the job type, and the job category.

  [-jobuuid] (privilege: advanced)
  Displays the job ID, the job name, the owning Vserver, and the job UUID.

  [-instance ]
  If you specify the `-instance` parameter, the command displays detailed information about all fields.

[-id <integer>] - Job ID
  Selects the jobs that match the ID or range of IDs that you specify.

[-vserver <vserver name>] - Owning Vserver
  Selects jobs that are owned by the specified Vserver.

[-name <text>] - Name
  Selects the jobs that match this parameter value.

[-description <text>] - Description
  Selects the jobs that match this parameter value.

[-priority {Low|Medium|High|Exclusive}] - Priority
  Selects the jobs that match this parameter value.
```
[-node <nodename>] - Node
Selects the jobs that match this parameter value.

[-affinity {Cluster|Node}] - Affinity
Selects the jobs that match this parameter value.

[-schedule <job_schedule>] - Schedule
Selects the jobs that match this parameter value.

[-queuetime <MM/DD HH:MM:SS>] - Queue Time
Selects the jobs that match this parameter value.

[-starttime <MM/DD HH:MM:SS>] - Start Time
Selects the jobs that match this parameter value.

[-endtime <MM/DD HH:MM:SS>] - End Time
Selects the jobs that match this parameter value.

[-dropdeadtime <MM/DD HH:MM:SS>] - Drop-dead Time
Selects the jobs that match this parameter value.

[-restarted {true|false}] - Restarted?
Selects the jobs that match this parameter value.

[-state {Initial|Queued|Running|Waiting|Pausing|Paused|Quitting|Success|Failure|Reschedule|Error|Quit|Dead|Unknown|Restart|Dormant}] - State
Selects the jobs that match this parameter value.

[-code <integer>] - Status Code
Selects the jobs that match this parameter value.

[-completion <text>] - Completion String
Selects the jobs that match this parameter value.

[-jobtype <text>] - Job Type
Selects the jobs that match this parameter value.

[-category <text>] - Job Category
Selects the jobs that match this parameter value.

[-uuid <UUID>] - UUID (privilege: advanced)
Selects the jobs that match this parameter value.

[-progress <text>] - Execution Progress
Selects the jobs that match this parameter value.

[-username <text>] - User Name
Selects the jobs that match this parameter value.

[-restart-is-delayed-by-module <text>] - Restart Is Delayed by Module
Selects jobs which are or were delayed by the specified module during the restart. For example:
MCC_SWITCHBACK

**Examples**

The following example displays information about all jobs on the node named node1:

```
cluster1:/> job show -node node1
Owning
Job ID Name            Vserver  Node         State
------ ---------------- --------- ------------ ----------
308114 mirror-daily-3587206
```
**job show-bynode**

Display a list of jobs by node

**Availability:** This command is available to cluster and Vserver administrators at the admin privilege level.

**Description**
The `job show-bynode` command displays information about jobs on a per-node basis. The command output depends on the parameters specified with the command. If no parameters are specified, the command displays information about all jobs in the cluster that are currently owned by a node.

To display detailed information about a specific job, run the command with the `-id` parameter. The detailed view includes all of the default information plus additional items.

You can specify additional parameters to display only information that matches the values you specify for those parameters. For example, to display information only about jobs running on a specific node, run the command with the `-node` parameter.

**Parameters**

```
{} [-fields <fieldname>, ...]
```

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

```
| [-instance ] |
```

If you specify the `-instance` parameter, the command displays detailed information about all fields.

```
[-node <nodename>|local ] - Node
```

Use this parameter to display information only about the jobs that are associated with the node you specify.

```
[-id <integer>] - Job ID
```

Use this parameter to display information only about the jobs that match the ID or range of IDs you specify.

```
[-vserver <vserver name>] - Owning Vserver
```

Use this parameter with the name of a Vserver to display only jobs that are owned by that Vserver.

```
[-name <text>] - Name
```

Use this parameter to display information only about the jobs that match the job name you specify.

```
[-description <text>] - Description
```

Use this parameter to display information only about the jobs that match the description you specify.

```
[-affinity {Cluster|Node}] - Affinity
```

Use this parameter with an affinity value to display only jobs that match the affinity you specify.
[-username <text>] - User Name

Use this parameter with a username to display only jobs that are associated with that user.

Examples
The following example displays information about all jobs on a per-node basis:

node::> job show-by-node

<table>
<thead>
<tr>
<th>Node</th>
<th>Job ID</th>
<th>Name</th>
<th>Vserver</th>
<th>Affinity</th>
</tr>
</thead>
<tbody>
<tr>
<td>node0</td>
<td>1501</td>
<td>log-rotation</td>
<td>node-vserver</td>
<td>Cluster</td>
</tr>
<tr>
<td>node1</td>
<td>1498</td>
<td>log-rotation</td>
<td>node-vserver</td>
<td>Cluster</td>
</tr>
<tr>
<td>node2</td>
<td>1499</td>
<td>log-rotation</td>
<td>node-vserver</td>
<td>Cluster</td>
</tr>
<tr>
<td>node3</td>
<td>1500</td>
<td>log-rotation</td>
<td>node-vserver</td>
<td>Cluster</td>
</tr>
</tbody>
</table>

job show-cluster

Display a list of cluster jobs

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The job show-cluster command displays information about cluster-affiliated jobs. The command output depends on the parameters specified with the command. If no parameters are specified, the command displays information about all cluster-affiliated jobs.

To display detailed information about a specific job, run the command with the -id parameter. The detailed view includes all of the default information plus additional items.

You can specify additional parameters to display only information that matches the values you specify for those parameters. For example, to display information only about jobs running on a specific node, run the command with the -node parameter.

Parameters

[-fields <fieldname>, ...]
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use ‘-fields ?’ to display the fields to specify.

[-instance]
If you specify the -instance parameter, the command displays detailed information about all fields.

[-id <integer>] - Job ID
Use this parameter to display information only about the jobs that match the ID or range of IDs you specify.

[-vserver <vserver name>] - Owning Vserver
Use this parameter with the name of a Vserver to display only jobs that are owned by that Vserver.

[-name <text>] - Name
Use this parameter to display information only about the jobs that match the job name you specify.

[-description <text>] - Description
Use this parameter to display information only about the jobs that match the description you specify.
Use this parameter to display information only about the jobs that match the priority you specify.

Use this parameter to display information only about the jobs that are associated with the node you specify.

Use this parameter with an affinity value to display only jobs that match the affinity you specify.

Use this parameter to display information only about the jobs that run on the schedule you specify.

Use this parameter to display information only about the jobs that match the queue time you specify.

Use this parameter to display information only about the jobs that match the start time you specify.

Use this parameter to display information only about the jobs that match the end time you specify.

Use this parameter to display information only about the jobs that match the final timeout time you specify.

Use this parameter to display information only about the jobs that match the restart value you specify.

Use this parameter to display information only about the jobs that match the job state you specify.

Use this parameter to display information only about the jobs that match the status code you specify.

Use this parameter to display information only about the jobs that match the completion text you specify.

Use this parameter to display information only about the jobs that match the job type you specify.

Use this parameter to display information only about the jobs that match the job category you specify.

Use this parameter to display information only about the jobs that match the UUID you specify.

Use this parameter with a username to display only jobs that are associated with the user you specify.

Examples
The following example displays information about all cluster-affiliated jobs:

class1::> job show-cluster

<table>
<thead>
<tr>
<th>Job ID</th>
<th>Name</th>
<th>Owning</th>
<th>Vserver</th>
<th>Node</th>
<th>State</th>
</tr>
</thead>
<tbody>
<tr>
<td>305</td>
<td>Auto_Mirror</td>
<td>node-vserver</td>
<td>-</td>
<td></td>
<td>Running</td>
</tr>
<tr>
<td>6202</td>
<td>mirror-03_10</td>
<td>node-vserver</td>
<td>-</td>
<td></td>
<td>Queued</td>
</tr>
<tr>
<td>6203</td>
<td>mirror-04_10</td>
<td>node-vserver</td>
<td>-</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Descr: Auto mirror
job show-completed

Display a list of completed jobs

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The job show-completed command displays information about completed jobs. The command output depends on the parameters you specify with the command. If you do not use any parameters, the command displays information about all completed jobs.

To display detailed information about a specific job, run the command with the -id parameter. The detailed view includes all of the default information plus additional items.

You can specify additional parameters to display only information that matches those parameters. For instance, to display information only about jobs running on a specific node, run the command with the -node parameter.

Parameters

{ [-fields <fieldname>, ...]
  If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use ‘-fields ?’ to display the fields to specify.
]

[ [-instance]]
  If you specify the -instance parameter, the command displays detailed information about all fields.

[-id <integer>] - Job ID
Use this parameter to display information only about the jobs that match the ID or range of IDs you specify.

[-vserver <vserver name>] - Owning Vserver
Use this parameter with the name of a Vserver to display only jobs that are owned by that Vserver.

[-name <text>] - Name
Use this parameter to display information only about the jobs that match the name you specify.

[-description <text>] - Description
Use this parameter to display information only about the jobs that match the description you specify.

[-priority {Low|Medium|High|Exclusive}] - Priority
Use this parameter to display information only about the jobs that match the priority you specify.

[-node <nodename>] - Node
Use this parameter to display information only about the jobs that are associated with the node you specify.

[-affinity {Cluster|Node}] - Affinity
Use this parameter with an affinity value to display only jobs that match the affinity you specify.
If you use this parameter, the command displays information only about the jobs that have the schedule you specify.

**-queuetime <MM/DD HH:MM:SS>** - Queue Time

If you use this parameter, the command displays information only about the jobs that have the queue time you specify.

**-starttime <MM/DD HH:MM:SS>** - Start Time

Use this parameter to display information only about the jobs that have the start time you specify.

**-endtime <MM/DD HH:MM:SS>** - End Time

Use this parameter to display information only about the jobs that have the end time you specify.

**-dropdeadt ime <MM/DD HH:MM:SS>** - Drop-dead Time

Use this parameter to display information only about the jobs that time out at the time you specify.

**-restarted {true|false}** - Restarted?

Use this parameter to display information only about the jobs that match the restart value you specify.

**-state {Initial|Queued|Running|Waiting|Pausing|Paused|Quitting|Success|Failure|Reschedule|Error|Quit|Dead|Unknown|Restart|Dormant}** - State

Use this parameter to display information only about the jobs that match the job state you specify.

**-code <integer>** - Status Code

Use this parameter to display information only about the jobs that match the status code you specify.

**-completion <text>** - Completion String

Use this parameter to display information only about the jobs that match the completion text you specify.

**-jobtype <text>** - Job Type

Use this parameter to display information only about the jobs that match the job type you specify.

**-category <text>** - Job Category

Use this parameter to display information only about the jobs that match the job category you specify.

**-uuid <UUID>** - UUID

Use this parameter to display information only about the jobs that match the UUID you specify.

**-username <text>** - User Name

Use this parameter with a username to display only jobs that are associated with that user.

**Examples**

The following example displays information about all completed jobs:

```
node::> job show-completed

Owning  Job ID Name            Vserver  End Time       Code       Completion String
-------- --------------- -------- -------------- ---------- --------------------
305      Auto_Mirror    node-vserver  10/10 08:07:05 0  Succeeded
6202     mirror-03_10   node-vserver  10/10 11:10:07 0
6203     mirror-04_10   node-vserver  10/10 12:10:09 0
6204     mirror-01_10   node-vserver  10/10 09:10:03 0
6205     mirror-02_10   node-vserver  10/10 10:10:08 0
6206     mirror-05_10   node-vserver  10/10 05:10:04 0
```
job stop

Stop a job

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The job stop command stops a running job. A stopped job cannot be resumed. Use the job pause command to pause a job so that you can later resume it. Use the job show command to view a list of running jobs.

Parameters
- **-id <integer>** - Job ID
  
  The numeric ID of the job to stop. A job ID is a positive integer.

  [-vserver <vserver name>] - Owning Vserver

  Use this parameter to specify the name of the Vserver that owns the job.

Examples
The following example stops the job that has ID 101:

```
cluster1::> job stop -id 101
```

job unclaim

Unclaim a cluster job

Availability: This command is available to cluster and Vserver administrators at the advanced privilege level.

Description
The job unclaim command causes a cluster-affiliated job that is owned by an unavailable node to be unclaimed by that node. Another node in the cluster can then take ownership of the job. Use the job show-cluster command to obtain a list of cluster-affiliated jobs.

Parameters
- **-id <integer>** - Job ID

  Use this parameter to specify the ID number of the job to unclaim.

  [-vserver <vserver name>] - Owning Vserver

  Use this parameter to specify the name of the Vserver that owns the job.

Examples
The following example shows how to unclaim the cluster-affiliated job with the ID 27 that is owned by the Vserver vs1:

```
cluster1::*> job unclaim -vserver vs1 -id 27
```
job watch-progress

Watch the progress of a job

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

**Description**

The *job watch-progress* command displays the progress of a job, and periodically updates that display. You can specify the frequency of the updates.

**Parameters**

- `-id <integer>` - Job ID
  
  Use this parameter to specify the numeric ID of the job to monitor.

- `[-vserver <vserver name>]` - Owning Vserver
  
  Use this parameter to specify the name of the Vserver that owns the job.

- `[-interval <integer>]` - Refresh Interval (seconds)
  
  Use this parameter to specify the number of seconds between updates.

**Examples**

The following example show how to monitor the progress of the job that has ID 222 on Vserver *vs0*. The progress display updates every 3 seconds.

```
cluster1::> job watch-progress -vserver vs0 -id 222 -interval 3
```

job history commands

The history directory

**job history show**

Display a history of jobs

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

**Description**

The *job history show* command displays a history of completed jobs with newer entries displayed first. You can specify optional parameters to select information about job history items that match only those parameters. For example, to display information about jobs that were completed on February 27 at noon, run the command with `-endtime "02/27 12:00:00"`.

**Parameters**

- `[-fields <fieldname>, ...]`
  
  If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

- `[-instance ]`
  
  If you specify the `-instance` parameter, the command displays detailed information about all fields.
[-node <nodename>|local] - Node
Selects the completed jobs that match this parameter value.

[-record <Sequence Number>] - Record ID
Selects the completed jobs that match the record ID or range of record IDs you specify. Note that record IDs are unique for each node, not for the cluster as a whole. As a result, there can be two records with the same record ID within the cluster.

[-vserver <vserver name>] - Owning Vserver
Selects the completed jobs that are owned by the Vserver you specify.

[-id <integer>] - Job ID
Selects the completed jobs that match this parameter value.

[-endtime <MM/DD HH:MM:SS>] - End Time
Selects jobs that completed at the time you specify. This parameter is most useful when used with a range of times.

[-starttime <MM/DD HH:MM:SS>] - Start Time
Selects completed jobs that were started at the time you specify. This parameter is most useful when used with a range of times.

[-name <text>] - Name
Selects the completed jobs that match this parameter value.

[-description <text>] - Description
Selects the completed jobs that match this parameter value.

[-code <integer>] - Status Code
Selects the completed jobs that match this parameter value. Each job defines its own status codes. The completion text is more informative, but support technicians may request this numeric code.

[-progress <text>] - Progress String
Selects the completed jobs that match this parameter value.

[-completion <text>] - Completion String
Selects the completed jobs that match this parameter value.

[-jobuuid <UUID>] - Job UUID (privilege: advanced)
Selects the completed jobs that match this parameter value.

[-event-type {Idle|Running|Succeeded|Failed|Paused|Stopped|Deleted|Error}] - Event Type
Selects the completed jobs that match this parameter value.

[-event-time <MM/DD HH:MM:SS>] - Event Time
Selects the completed jobs that match this parameter value. This parameter is most useful when used with a range of times.

[-error-code <integer>] - Job Manager Error Code
Selects the completed jobs that match this parameter value.

[-error-text <text>] - Job Manager Error Text
Selects the completed jobs that match this parameter value.

[-username <text>] - User Name
Selects the completed jobs that match this parameter value.

Examples
The following example displays information about all completed jobs:

job history commands
The following example shows how to use a range with the "endtime" parameter to select only the events that ended between 8:15 and 8:16 on August 22nd.

```
cluster1::> job history show -endtime "08/22 08:15:00".."08/22 08:16:00"
```

```
<table>
<thead>
<tr>
<th>Time</th>
<th>Node</th>
<th>Vserver</th>
<th>Name</th>
<th>Event</th>
<th>Job ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>08/22 08:15:03 node1 node1-vs</td>
<td>CLUSTER BACKUP AUTO weekly</td>
<td>Running</td>
<td>4</td>
<td></td>

</tr>
<tr>
<td>08/22 08:15:08 node1 node1-vs</td>
<td>CLUSTER BACKUP AUTO weekly</td>
<td>Idle</td>
<td>4</td>
<td></td>
<td></td>
</tr>
<tr>
<td>08/22 08:15:03 node1 node1-vs</td>
<td>CLUSTER BACKUP AUTO weekly</td>
<td>Running</td>
<td>4</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

3 entries were displayed.
```

**job initstate commands**

Display the initialization state of job managers

**job initstate show**

Display init state for job managers

**Availability:** This command is available to cluster administrators at the advanced privilege level.

**Description**

The **job initstate show** command displays information about the initialization states of job-manager processes.

**Parameters**

```
[-fields <fieldname>, ...]
```

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use **-fields ?** to display the fields to specify.

```
[-instance]
```

If you specify the **-instance** parameter, the command displays detailed information about all fields.
[-node <nodename>|local] - Node
Selects the nodes that match this parameter value.

[-process <process_name>] - Process Name
Selects the nodes that match this parameter value.

[-initialized {true|false}] - Initialized?
Selects the nodes that match this parameter value (true means initialized; false means not initialized).

[-cache-root <text>] - Cache Root
Selects the nodes that match this parameter value.

[-siteid <UUID>] - Site ID
Selects the nodes that match this parameter value.

[-hp-threads <integer>] - High Priority Threads
Selects the nodes that have the number of high-priority threads you specify.

[-mp-threads <integer>] - Medium Priority Threads
Selects the nodes that have the number of medium-priority threads you specify.

[-lp-threads <integer>] - Low Priority Threads
Selects the nodes that have the number of low-priority threads you specify.

[-tx-interval <integer>] - Transaction Interval
Selects the nodes that have the number of seconds you specify as their transaction interval.

[-initmsg <text>] - Initialization Message
Selects the nodes that match this parameter value.

[-thread-initmsg <text>] - Thread Initialization Message
Selects the nodes that match this parameter value. The thread initialization message contains information about thread status. If there is no information to communicate, this message is empty.

[-recovery-enabled {true|false}] - Job Failover Enabled?
Selects the nodes that match this parameter value (true means enabled, false means not enabled).

[-ex-threads <integer>] - Exclusive Priority Threads
Selects the nodes that match this parameter value.

**Examples**

The following example shows how to display general job-manager initialization-state information for a cluster.

```
cluster1::*> job initstate show
Node              Process     Init? Thr  Thr  Thr  Thr  TX Int Failover?
----------------- ----------- ----- ---- ---- ---- ---- ------- ---------
nodename1          mgwd        true  2    3    5    8    300    true
node0               mgwd        true  2    3    5    8    300    true
2 entries were displayed.
```

The following example shows how to display detailed job-manager initialization-state information for a node named node0.

```
cluster1::*> job initstate show -instance -node node0
Node: node0
Process Name: mgwd
Initialized?: true
Cache Root: /mroot/jm_cache
Site ID: 824e8f7d-f49-1d9-84af-00423b7352
High Priority Threads: 2
Medium Priority Threads: 3
Low Priority Threads: 5
```
Transaction Interval: 300
Initialization Message: Initialized
Are Threads Running?: -
Job Failover Enabled?: true
Exclusive Priority Threads: 8

job private commands
Manage private jobs

job private delete
Delete a job

Availability: This command is available to cluster and Vserver administrators at the advanced privilege level.

Description
The job private delete command deletes a private job. Private jobs are affiliated with a specific node and do not use any cluster facilities, such as the replicated database.

If you use this command on a job that does not support the delete operation, the command returns an error message.

Use the job private show command to view a list of private jobs that can be deleted.

Parameters

-node {@nodename}@local - Node
Use this parameter to specify the node with which the private job is associated.

-id <integer> - Job ID
Use this parameter to specify the numeric ID of the private job to be deleted. A job ID is a positive integer.

[-vserver <vserver name>] - Owning Vserver
Use this parameter to specify the name of the Vserver that owns the job.

Examples
The following example shows how to delete the job that has ID 273 from the node named node2:

```
cluster1:~*> job private delete -node node2 -id 273
```

job private show on page 140

job private pause
Pause a job

Availability: This command is available to cluster and Vserver administrators at the advanced privilege level.

Description
The job private pause command pauses a private job. Private jobs are affiliated with a specific node and do not use any cluster facilities, such as the replicated database.

If you use this command to pause a job that does not support it, the command returns an error message.
Use the `job private resume` command to resume a paused private job.

Use the `job private show` command to view a list of private jobs.

**Parameters**

- `-node {<nodename>|local}` - Node
  
  Use this parameter to specify the node with which the private job is associated.

- `-id <integer>` - Job ID
  
  Use this parameter to specify the numeric ID of the paused private job to be paused. A job ID is a positive integer.

- `[-vserver <vserver name>]` - Owning Vserver
  
  Use this parameter to specify the name of the Vserver that owns the job.

### Examples

The following example pauses the private job that has ID 99 on the node `node1`:

```bash
cluster1::*> jobs private pause -node node1 -id 99
```

### Related references

- `job private resume` on page 139
- `job private show` on page 140

---

**job private resume**

Resume a job.

**Availability:** This command is available to cluster and Vserver administrators at the `advanced` privilege level.

**Description**

The `job private resume` command resumes a private job that was paused by using the `job private pause` command. Private jobs are affiliated with a specific node and do not use any cluster facilities, such as the replicated database.

Use the `job private show` command to view a list of paused private jobs that can be resumed.

**Parameters**

- `-node {<nodename>|local}` - Node
  
  Use this parameter to specify the node with which the paused private job is associated.

- `-id <integer>` - Job ID
  
  Use this parameter to specify the numeric ID of the paused private job to be resumed. A job ID is a positive integer.

- `[-vserver <vserver name>]` - Owning Vserver
  
  Use this parameter to specify the name of the Vserver that owns the job.

### Examples

The following example resumes the paused private job that has ID 99 on a node named `node2`:

```bash
cluster1::*> job private resume -node node2 -id 99
```
Related references

- `job private pause` on page 138
- `job private show` on page 140

**job private show**

Display a list of jobs

**Availability:** This command is available to `cluster` and `Vserver` administrators at the `advanced` privilege level.

**Description**

The `job private show` command displays information about private jobs. Private jobs are affiliated with a specific node and do not use any cluster facilities, such as the replicated database.

**Parameters**

- `[-fields <fieldname>, ...]`  
  If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

- `[-inprogress]`  
  Displays the job ID, name, owning Vserver, and progress of each private job.

- `[-jobstate]`  
  Displays information about each private job's state, including the queue state, whether the job was restarted, and when the job has timed out.

- `[-jobuuid]`  
  Displays the ID, name, owning Vserver, and UUID of each private job.

- `[-sched]`  
  Displays the job ID, name, owning Vserver, and run schedule of each private job.

- `[-times]`  
  Displays the queue time, start time, and end time of each private job.

- `[-type]`  
  Displays the type and category of each private job.

- `[-instance]`  
  If you specify the `-instance` parameter, the command displays detailed information about all fields.

- `[-node <nodename> | local]` - Node
  Selects the private jobs that match this parameter value.

- `[-id <integer>]` - Job ID
  Selects the private jobs that match the ID or range of IDs that you specify.

- `[-vserver <vserver name>]` - Owning Vserver
  Selects the private jobs that match this parameter value.

- `[-name <text>]` - Name
  Selects the private jobs that match this parameter value.

- `[-description <text>]` - Description
  Selects the private jobs that match this parameter value.

- `[-priority Low | Medium | High | Exclusive]` - Priority
  Selects the private jobs that match this parameter value.
[-schedule <job_schedule>] - Schedule
Selects the private jobs that match this parameter value.

[-queuetime <MM/DD HH:MM:SS>] - Queue Time
Selects the private jobs that match this parameter value.

[-starttime <MM/DD HH:MM:SS>] - Start Time
Selects the private jobs that match this parameter value.

[-endtime <MM/DD HH:MM:SS>] - End Time
Selects the private jobs that match this parameter value.

[-dropdeadtime <MM/DD HH:MM:SS>] - Drop-dead Time
Selects the private jobs that match this parameter value.

[-restarted {true|false}] - Restarted?
Selects the private jobs that match this parameter value.

[-state {Initial|Queued|Running|Waiting|Pausing|Paused|Quitting|Success|Failure|Reschedule|Error|Quit|Dead|Unknown|Restart|Dormant}] - State
Selects the private jobs that match this parameter value.

[-code <integer>] - Status Code
Selects the private jobs that match this parameter value.

[-completion <text>] - Completion String
Selects the private jobs that match this parameter value.

[-jobtype <text>] - Job Type
Selects the private jobs that match this parameter value.

[-category <text>] - Job Category
Selects the private jobs that match this parameter value.

[-uuid <UUID>] - UUID
Selects the private jobs that match this parameter value.

[-progress <text>] - Execution Progress
Selects the private jobs that match this parameter value.

[-username <text>] - User Name
Selects the private jobs that match this parameter value.

Examples
The following example displays information about all private jobs on the local node:

```
cluster1::*> job private show -node local
Node: node1
Job ID Name                Vserver    State
------- -------------------- ---------- -----------
3      snap-hourly         cluster1   Queued
Description: Auto-Snapshot
4      snap-daily          cluster1   Queued
Description: Auto-Snapshot
5      snap-weekly         cluster1   Queued
Description: Auto-Snapshot
6      sync task           cluster1   Queued
Description: sync task
7      ldap-certs          cluster1   Queued
Description: ldap resync
5 entries were displayed.
```
job private show-completed

Display a list of completed jobs.

Availability: This command is available to cluster and Vserver administrators at the advanced privilege level.

Description
The job private show-completed command displays information about completed private jobs. Private jobs are affiliated with a specific node and do not use any cluster facilities, such as the replicated database.

Parameters

{ [-fields <fieldname>, ...]
  If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use -fields '?' to display the fields to specify.
  }
[-instance]
  If you specify the -instance parameter, the command displays detailed information about all fields.

[-node {<nodename>|local}] - Node
  Use this parameter to display information only about completed jobs that are associated with the node you specify.

[-id <integer>] - Job ID
  Use this parameter to display information only about completed jobs that have the ID you specify.

[-vserver <vserver name>] - Owning Vserver
  Use this parameter to display only completed jobs that are owned by the Vserver you specify.

[-name <text>] - Name
  Use this parameter to display information only about completed jobs that have the name you specify.

[-description <text>] - Description
  Use this parameter to display information only about completed jobs that have the description you specify.

[-priority {Low|Medium|High|Exclusive}] - Priority
  Use this parameter to display information only about completed jobs that have the priority you specify.

[-schedule <job_schedule>] - Schedule
  Use this parameter to display information only about completed jobs that have the schedule you specify.

[-queuetime <MM/DD HH:MM:SS>] - Queue Time
  Use this parameter to display information only about completed jobs that have the queue time you specify.

[-starttime <MM/DD HH:MM:SS>] - Start Time
  Use this parameter to display information only about completed jobs that have the start time you specify.

[-endtime <MM/DD HH:MM:SS>] - End Time
  Use this parameter to display information only about completed jobs that have the end time you specify.

[-dropdeadtime <MM/DD HH:MM:SS>] - Drop-dead Time
  Use this parameter to display information only about completed jobs that have the final timeout time you specify.

[-restarted {true|false}] - Restarted?
  Use this parameter to display information only about completed jobs that have the restart value you specify.

[-state {Initial|Queued|Running|Waiting|Pausing|Paused|Quitting|Success|Failure|Reschedule|Error|Quit|Dead|Unknown|Restart|Dormant}] - State
  Use this parameter to display information only about completed jobs that have the job state you specify.
[-code <integer>] - Status Code
Use this parameter to display information only about completed jobs that have the status code you specify.

[-completion <text>] - Completion String
Use this parameter to display information only about completed jobs that have the completion text you specify.

[-jobtype <text>] - Job Type
Use this parameter to display information only about completed jobs that have the job type you specify.

[-category <text>] - Job Category
Use this parameter to display information only about completed jobs that have the job category you specify.

[-uuid <UUID>] - UUID
Use this parameter to display information only about completed jobs that have the UUID you specify.

[-username <text>] - User Name
Use this parameter to display information only about completed jobs that are associated with the user you specify.

Examples
The following example shows how to display information about all completed private jobs on the node named node1:

```
cluster1::*> job private show-completed -node node1
Node: node1

<table>
<thead>
<tr>
<th>Job ID</th>
<th>Name</th>
<th>Vserver</th>

job private stop
Stop a job

Availability: This command is available to cluster and Vserver administrators at the advanced privilege level.

Description
The job private stop command stops a running private job. A private job is a job that is associated with a specific node and does not use cluster facilities. A stopped job cannot be restarted.

Parameters

- **-node {<nodename>|local}** - Node
  This specifies the node on which the job is running.

- **-id <integer>** - Job ID
  This specifies the numeric ID of the job that is to be stopped.

[-vserver <vserver name>] - Owning Vserver
Use this parameter to specify the name of the Vserver that owns the job.

Examples
The following example stops a private job with the ID 416 on a node named node0:
job private watch-progress

Watch the progress of a job

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *advanced* privilege level.

**Description**

The `job private watch-progress` command displays and periodically updates the progress of a private job. A private job is a job that is associated with a specific node and does not use cluster facilities. You can specify the frequency of the progress updates.

**Parameters**

- `-node {<nodename>|local}` - Node
  
  This specifies the node on which the job is running.

- `-id <integer>` - Job ID
  
  This specifies the numeric ID of the job whose progress is to be monitored.

- `[-vserver <vserver name>]` - Owning Vserver
  
  Use this parameter to specify the Vserver with which the paused private job is associated. Use this parameter to specify the name of the Vserver that owns the job.

- `[-interval <integer>]` - Refresh Interval (seconds)
  
  This optionally specifies, in seconds, the frequency of the updates.

**Examples**

The following example monitors the progress of the private job that has ID 127 on a node named node1. The progress is updated every 2 seconds.

```
cluster1::*> job private watch-progress -node node1 -id 127 -interval 2
```

Queued

---

job schedule commands

Manage job schedules

**job schedule delete**

Delete a schedule

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**

The `job schedule delete` command deletes a schedule. Use the `job schedule show` command to display all current schedules.

You cannot delete any schedules that are in use by jobs. Use the `job schedule show-jobs` command to display jobs by schedule.

You cannot delete any schedules that are referenced by:
• Volume Snapshot copy policy entries
• SnapMirror entries
• SIS policy entries
• configuration backup settings

You must remove all references to a schedule before you can delete it. If you attempt to delete a schedule that is referenced, an error message will list which entries reference the schedule you want to delete. Use the show command for each of the items listed by the error message to display which entries reference the schedule. You may need to use the -instance parameter to display more detail.

Parameters
-name <text> - Schedule Name

Use this parameter with the name of an existing schedule to specify the schedule you want to delete.

Examples
The following example deletes a schedule named overnightbackup:

```
cluster1::> job schedule delete -name overnightbackup
```

job schedule show

Display a list of available schedules

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The job schedule show command displays information about schedules.

Parameters

{-fields <fieldname>,...}

If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use -fields ? to display the fields to specify.

[-instance ]

If you specify the -instance parameter, the command displays detailed information about all fields.

[-name <text>] - Schedule Name
Selects the schedules that match this parameter value.

[-type {cron|interval|builtin}] - Schedule Type
Selects the schedules that match this parameter value.

[-description <text>] - Description
Selects the schedules that match this parameter value.

Examples
The following example displays information about all cron schedules:
job schedule show-jobs

Display the list of jobs by schedule

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The job schedule show-jobs command displays information about jobs that are associated with schedules.

Parameters

\[-fields <fieldname>, ...\]
If you specify the \[-fields <fieldname>, ...\] parameter, the command output also includes the specified field or fields. You can use \'-fields ?\' to display the fields to specify.

\[-instance\]
If you specify the \[-instance\] parameter, the command displays detailed information about all fields.

\[-name <text>\] - Schedule Name
Use this parameter to display information only about the jobs that are associated with the schedule you specify.

\[-affinity {Cluster|Node}] - Cluster / Node
Use this parameter to display information only about the jobs that match the affinity value you specify.

\[-owner <text>] - Owner
Use this parameter to display information only about the jobs that are owned by the nodes you specify.

\[-jobid <integer>] - ID
Use this parameter to display information only about the jobs that match the ID or range of IDs that you specify.

\[-jobname <text>] - Job Name
Use this parameter to display information only about the jobs that match the name you specify.

Examples
The following example shows information about schedules that are associated with jobs:

```
cluster1::> job schedule show-jobs
Name          Type      Owner                  Job ID     Job Name
------------  --------- ---------------------  ---------- ---------------------
hourly        Cluster   -                      98644      mirror-hourly
weeklylog     Node      node0                  1501       log-rotation
weeklylog     Node      node1                  1498       log-rotation
weeklylog     Node      node2                  1499       log-rotation
weeklylog     Node      node3                  1500       log-rotation
5 entries were displayed.
```
job schedule cron commands

Manage cron-type job schedules

job schedule cron create

Create a cron schedule

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The job schedule cron create command creates a cron schedule. A cron schedule, like a UNIX cron job, runs at a specified time. You can also specify months, days of the month, or days of the week on which the schedule will run.

If you specify values for both days of the month and days of the week, they are considered independently. For example, a cron schedule with the day specification Friday, 13 runs every Friday and on the 13th day of each month, not just on every Friday the 13th.

Parameters

- **-name <text>** - Name
  
  Use this parameter to specify the name of the interval schedule that you want to create.

- **[-month <cron_month>, ...]** - Month
  
  Use this parameter to specify months in which the schedule runs. Valid values are January, February, March, April, May, June, July, August, September, October, November, December, and all. Specify "all" to run the schedule every month.

- **[-dayofweek <cron_dayofweek>, ...]** - Day of Week
  
  Use this parameter to specify days of the week on which the schedule runs. Valid values are Sunday, Monday, Tuesday, Thursday, Friday, and Saturday, and all. Specify "all" to run the schedule every day.

- **[-day <cron_dayofmonth>, ...]** - Day
  
  Use this parameter to specify days of the month on which the schedule runs. Valid values range from 1 to 31.

- **[-hour <cron_hour>, ...]** - Hour
  
  Use this parameter to specify the hours value of the time of day at which the schedule runs. Valid values range from 0 (midnight) to 23 (11:00 p.m.). Specify "all" to run the schedule every hour.

- **-minute <cron_minute>, ...** - Minute
  
  Use this parameter to specify the minutes portion of the time of day at which the schedule runs. Valid values range from 0 to 59.

Examples

The following example creates a cron schedule named weekendcron that runs on weekend days (Saturday and Sunday) at 3:00 a.m.

```
cluster1:~> job schedule cron create -name weekendcron -dayofweek "Saturday, Sunday" -hour 3 -minute 0
```

job schedule cron delete

Delete a cron schedule

Availability: This command is available to cluster administrators at the admin privilege level.
**Description**

The `job schedule cron delete` command deletes a cron schedule. Use the `job schedule cron show` command to display all current cron schedules.

You cannot delete any cron schedules that are associated with jobs. Use the `job schedule show-jobs` command to display jobs by schedule.

**Parameters**

- `-name <text>` - Name
  
  Use this parameter with the name of an existing cron schedule to specify the cron schedule that you want to delete.

**Examples**

The following example deletes a cron schedule named midnightcron:

```
cluster1::> job schedule cron delete -name midnightcron
```

- `job schedule show-jobs` on page 146

---

**job schedule cron modify**

Modify a cron schedule

**Availability:** This command is available to `cluster` administrators at the `admin` privilege level.

**Description**

The `job schedule cron modify` command modifies a cron schedule. A cron schedule, like a UNIX cron job, runs at a specified time. You can also specify months, days of the month, or days of the week on which the schedule runs. Use the `job schedule cron show` command to display all current cron schedules. See the documentation for `job schedule cron show` for more information about how cron schedules work.

Modifying one parameter of a cron schedule does not affect the other parameters. For example, if cron schedule is set to run at 3:15 AM, and you modify the "hour" parameter to 4, the schedule's new time will be 4:15am. To clear a parameter of the schedule's interval, you must explicitly set that portion to "0" or "-" Some parameters can also be set to "all".

**Parameters**

- `-name <text>` - Name
  
  Use this parameter with the name of an existing cron schedule to specify the cron schedule you want to modify.

- `[-month <cron_month>, ...]` - Month
  
  Use this parameter to specify a new "month" value for the cron schedule. Valid values are January, February, March, April, May, June, July, August, September, October, November, December, or all. Specify "all" to run the schedule every month.

- `[-dayofweek <cron_dayofweek>, ...]` - Day of Week
  
  Use this parameter to specify a new "day of week" value for the cron schedule. Valid values include Sunday, Monday, Tuesday, Thursday, Friday, Saturday, or all. Specify "all" to run the schedule every day.

- `[-day <cron_dayofmonth>, ...]` - Day
  
  Use this parameter to specify a new "day of month" value for the cron schedule. Valid values range from 1 to 31.
-hour <cron_hour>, ...] - Hour

Use this parameter to specify a new "hour of the day" value for the cron schedule. Valid values range from 0 (midnight) to 23 (11:00 p.m.). Specify "all" to run the schedule every hour.

-minute <cron_minute>, ...] - Minute

Use this parameter to specify a new "minute of the hour" value for the cron schedule. Valid values range from 0 to 59.

Examples

The following example modifies a cron schedule named weekendcron so that it runs at 3:15 a.m.:

```
cluster1::> job schedule cron modify -name weekendcron -hour 3 -minute 15
```

job schedule cron show on page 149

job schedule cron show

Show cron schedules

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description

The job schedule cron show command displays information about cron schedules. A cron schedule runs a job at a specified time on specified days.

Parameters

{-fields <fieldname>, ...}

If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

{|-instance |}

If you specify the -instance parameter, the command displays detailed information about all fields.

{-name <text> ] - Name

Selects the cron schedules that match this parameter value.

{-month <cron_month>, ...] - Month

Selects the cron schedules that match this parameter value. Valid values are January, February, March, April, May, June, July, August, September, October, November, December, or all.

{-dayofweek <cron_dayofweek>, ...] - Day of Week

Selects the cron schedules that match this parameter value. Valid values include Sunday, Monday, Tuesday, Wednesday, Thursday, Friday, Saturday, or all.

{-day <cron_dayofmonth>, ...] - Day

Selects the cron schedules that match this parameter value. Valid values range from 1 to 31.

{-hour <cron_hour>, ...] - Hour

Selects the cron schedules that match this parameter value.

{-minute <cron_minute>, ...] - Minute

Selects the cron schedules that match the minute or range of minutes that you specify.
[[-description <text>] - Description]

Selects the cron schedules that match this parameter value.

Examples
The following example displays information about all current cron schedules:

```bash
cluster1::> job schedule cron show
Name                Description
----------------    -----------------------------------------------------
weekendcron         Sun,Sat@3:15
```

The following example displays information about the cron schedule named weekendcron:

```bash
cluster1::> job schedule cron show -name weekendcron
    Name: weekendcron
    Month: -
    Day of Week: Sunday, Saturday
    Day: -
    Hour: 3
    Minute: 15
    Description: Sun,Sat@3:15
```

**job schedule interval commands**

Manage interval-based job schedules

**job schedule interval create**

Create a schedule that runs on an interval

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**

The `job schedule interval create` creates an interval schedule. An interval schedule runs jobs at specified intervals after the previous job finishes. For instance, if a job uses an interval schedule of 12 hours and takes 30 minutes to complete, the job runs at the following times:

- Day one at 8:00 a.m. (the job's initial run)
- Day one at 8:30 p.m.
- Day two at 9:00 a.m.
- Day two at 9:30 p.m.

Each of the numerical parameters of the interval must be a whole number. These parameters can be used individually, or combined to define complex time values. For example, use a value of 1 day, 12 hours to create an interval of 1.5 days.

Large parameter values are converted into larger units. For example, if you create a schedule with an interval of 36 hours, the `job schedule interval show` command will display it with an interval of 1 day 12 hours.

**Parameters**

- `-name <text>` - Name
  
  Use this parameter to specify the name of the interval schedule you want to create.

- `[-days <integer>]` - Days
  
  Use this parameter to specify the "days" portion of the schedule's interval. A day is one calendar day.
[\texttt{-hours <integer>}] - Hours

Use this parameter to specify the "hours" portion of the schedule's interval.

[\texttt{-minutes <integer>}] - Minutes

Use this parameter to specify the "minutes" portion of the schedule's interval.

[\texttt{-seconds <integer>}] - Seconds

Use this parameter to specify the "seconds" portion of the schedule's interval.

\begin{verbatim}
Examples
The following example creates an interval schedule named rollingdaily that runs six hours after the completion of the previous occurrence of the job:

\texttt{cluster1::> job schedule interval create -name rollingdaily -hours 6}
\end{verbatim}

\textbf{Related references}

\textit{job schedule interval show} on page 152

\textbf{job schedule interval delete}

Delete an interval schedule

\textbf{Availability:} This command is available to \textit{cluster} administrators at the \textit{admin} privilege level.

\textbf{Description}

The \texttt{job schedule interval delete} command deletes an interval schedule. Use the \texttt{job schedule interval show} command to display all current interval schedules.

You cannot delete interval schedules that are currently being run. Use the \texttt{job schedule show-jobs} command to display jobs by schedule.

\textbf{Parameters}

\texttt{-name <text>} - Name

Use this parameter with the name of an existing interval schedule to specify the interval schedule you want to delete.

\begin{verbatim}
Examples
The following example deletes an interval schedule named rollingdaily:

\texttt{cluster1::> job schedule interval delete -name rollingdaily}
\end{verbatim}

\textbf{Related references}

\textit{job schedule interval show} on page 152

\textit{job schedule show-jobs} on page 146

\textbf{job schedule interval modify}

Modify an interval schedule

\textbf{Availability:} This command is available to \textit{cluster} administrators at the \textit{admin} privilege level.
Description
The `job schedule interval modify` command modifies an interval schedule. An interval schedule runs jobs at a specified interval after the previous job finishes. Use the `job schedule interval show` command to display all current interval schedules. See the documentation of `job schedule interval show` for more information on how interval schedules work.

Modifying one parameter of a schedule's interval does not affect the other parameters. For example, if a schedule's interval is 1 day 12 hours, and you modify the "hours" parameter to 16, the schedule's new interval is 1 day 16 hours. To clear a parameter of the schedule's interval, you must explicitly set that parameter to "0" or "-".

Parameters
- **-name <text>** - Name
  Use this parameter with the name of an existing interval schedule to specify the interval schedule you want to modify.
- **[-days <integer>]** - Days
  Use this parameter to specify a different "days" value for the schedule's interval.
- **[-hours <integer>]** - Hours
  Use this parameter to specify a different "hours" value for the schedule's interval.
- **[-minutes <integer>]** - Minutes
  Use this parameter to specify a different "minutes" value for the schedule's interval.
- **[-seconds <integer>]** - Seconds
  Use this parameter to specify a different "seconds" value for the schedule's interval.

Examples
The following example sets the schedule named rollingdaily to run every eight hours:

```
cluster1::> job schedule interval modify -name rollingdaily -hours 8
```

`job schedule interval show` on page 152
Show interval schedules

**Availability:** This command is available to cluster and Vserver administrators at the `admin` privilege level.

Description
The `job schedule interval show` command displays information about interval schedules.

Parameters
- **[-fields <fieldname>, ...]**
  If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.
- **[-instance]**
  If you specify the `-instance` parameter, the command displays detailed information about all fields.
- **[-name <text>]** - Name
  Selects the interval schedules that match this parameter value.
[-days <integer>] - Days
Selects the interval schedules that match the day value or range of values you specify.

[-hours <integer>] - Hours
Selects the interval schedules that match the hour value or range of values you specify.

[-minutes <integer>] - Minutes
Selects the interval schedules that match the minute value or range of values you specify.

[-seconds <integer>] - Seconds
Selects the interval schedules that match the second value or range of values you specify.

[-description <text>] - Description
Selects the interval schedules that match the description you specify.

Examples
The following example displays information about all interval schedules:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rollingdaily</td>
<td>Every 8h</td>
</tr>
</tbody>
</table>

lun commands

Manage LUNs

Note: These commands are unsupported for a Vserver with Infinite Volume.

lun create

Create a new LUN

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
This command creates a new LUN of a specific size. You cannot create a LUN at a path that already exists. You must create LUNs at the root of a volume or qtree. You can not create LUNs in the Vserver root volume.

You might find it useful to provide a meaningful path name for the LUN and containing volume. For example, you might choose a name that describes how the LUN is used, such as the name of the application, the type of data that it stores, or the user accessing the data. Examples are /vol/database/lun0, /vol/finance/lun1, and /vol/bill/lun2.

It is recommended that you distribute LUNs across the cluster.

When you can create a LUN, the size of the LUN could be larger than what you specified. The system generates a message if the size of the LUN is different from what you specified.

By default, when you create a LUN, it is online and it is space-reserved. Use the lun offline command to take a LUN offline. When you set space reserved to false, the LUN is non-space reserved.

Note: For non-space reserved LUNs, write operations to that LUN might fail due to insufficient disk space. As a result, the host application or operating system might crash.

Note: When you create a LUN from a file, that file cannot be deleted without deleting the LUN itself.
Note: This command is not supported for FlexGroups or Vservers with Infinite Volumes.

Parameters

-vserver <vserver name> - Vserver Name
   Specifies the Vserver.

{-path <path> - LUN Path
   Specifies the path of the new LUN. The LUN path cannot contain any files. Examples of correct LUN paths are /vol/vol1/lun1 and /vol/vol1/qtree1/lun1.

-volume <volume name> - Volume Name
   Specifies the volume that contains the new LUN.

{-qtree <qtree name> - Qtree Name
   Specifies the qtree that contains the new LUN.

-lun <text> - LUN Name
   Specifies the new LUN name. A LUN name is a case-sensitive name and has the following requirements:
   • Must contain one to 255 characters. Spaces are not allowed.
   • Can contain the letters A-Z, a-z, numbers 0-9, "," , "," , "," , "," , "," , "," , "," .

{-size | -s <size> - LUN Size
   Specifies the size of the LUN in bytes. You can specify a one-character multiplier suffix:
   • c (1 byte)
   • w (2 bytes)
   • B (512 bytes)
   • k (1024 bytes)
   • M (k*k bytes)
   • G (k*m bytes)
   • T (m*m bytes)

{-file-path | -f <text> - File Path
   Creates a LUN using the file path as the source.

{-foreign-disk <text> - Foreign Disk Serial number (privilege: advanced)
   LUN is created with the same attributes (size, alignment, bytes per sector and so on) as the specified foreign disk.

{-prefix-size | -P <size> - Prefix Size (privilege: advanced)
   Specifies the size of the prefix stream for the new LUN.

-ostype | -t <os_enum> - OS Type
   Specifies the OS type for the new LUN. The OS types are:
   • aix - the LUN stores AIX data.
   • hpux - the LUN stores HP-UX data.
   • hyper_v - the LUN stores Windows Server 2008 or Windows Server 2012 Hyper-V data
   • linux - the LUN stores a Linux raw disk without a partition table.
   • netware - the LUN stores NetWare data.
• openvms - the LUN stores Open-VMS data
• solaris - the LUN stores Solaris raw disk in a single-slice partition.
• solaris_efi - the LUN stores Solaris_EFI data.
• vmware - the LUN stores VMware data
• windows - the LUN stores a raw disk type in a single-partition Windows disk using the Master Boot Record (MBR) partitioning style.
• windows_gpt - the LUN stores Windows data using the GUID Partition Type (GPT) partitioning style.
• windows_2008 - the LUN stores Windows data for Windows 2008 and 2012 systems.
• xen - the LUN stores Xen data

[-space-reserve (enabled|disabled)] - Space Reservation
Specifies whether the space reservation setting is enabled or disabled for the new LUN. If you set the parameter to enabled, the LUN is space-reserved. If you set the parameter to disabled, the LUN is non-space reserved. The default is enabled.

[-comment <text>] - Comment
A description for the LUN you want to create. If the comment string contains white space, you must enclose the comment string in double quotes. The limit is 254 characters.

[-space-allocation (enabled|disabled)] - Space Allocation
Specifies the value for the space allocation attribute of the LUN. The space allocation attribute determines if the LUN supports the SCSI Thin Provisioning features defined in the Logical Block Provisioning section of the SCSI SBC-3 standard.

Specifying enabled for this parameter enables support for the SCSI Thin Provisioning features.

Specifying disabled for this parameter disables support for the SCSI Thin Provisioning features.

Hosts and file systems that do not support SCSI Thin Provisioning should not enable space allocation.

The default is disabled.

[-class (regular|protocol-endpoint|vvol)] - Class
Specifies the class of the new LUN. The class types are:
• regular - the LUN is for normal blocks protocol access. This is the default value.
• protocol-endpoint - the LUN is a vvol protocol endpoint.
• vvol - the LUN is a vvol data LUN.

[-qos-policy-group <text>] - QoS Policy Group
This optionally specifies which QoS policy group to apply to the LUN. This policy group defines measurable service level objectives (SLOs) that apply to the storage objects with which the policy group is associated. If you do not assign a policy group to a LUN, the system will not monitor and control the traffic to it.

Note: If you specify this parameter for a LUN that you want to create from a file and that file belongs to a QoS policy group, Data ONTAP adds the LUN to the specified policy group and removes the file from its policy group. Both the file and the LUN that you created from the file cannot belong to QoS policy groups.

[-caching-policy <text>] - Caching Policy Name
This optionally specifies the caching policy to apply to the LUN. A caching policy defines how the system caches this volume's data in Flash Cache modules. If a caching policy is not assigned to this LUN, the system uses the caching policy that is assigned to the containing volume or Vserver. If a caching policy is not assigned
to the containing volume or Vserver, the system uses the default cluster-wide policy. The available caching policies are:

- **none** - Does not cache any user data or metadata blocks.
- **auto** - Read caches all metadata and randomly read user data blocks, and write caches all randomly overwritten user data blocks.
- **meta** - Read caches only metadata blocks.
- **random_read** - Read caches all metadata and randomly read user data blocks.
- **random_read_write** - Read caches all metadata, randomly read and randomly written user data blocks.
- **all_read** - Read caches all metadata, randomly read and sequentially read user data blocks.
- **all_read_random_write** - Read caches all metadata, randomly read, sequentially read, and randomly written user data.
- **all** - Read caches all data blocks read and written. It does not do any write caching.

Default caching-policy is auto.

</tr>
</tbody>
</table>

**lun delete**

Delete the LUN

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

**Description**
This command deletes a LUN from a specified Vserver and volume. If the LUN is mapped and online, the force option is required to delete it.

If a LUN is mapped to an initiator group, you can unm ap it by using the `lun unmap` command. If a LUN is online, you take it offline by using the `lun offline` command.

**Note:** If you create a LUN from a file, you cannot remove the file while the LUN is linked to it. If you want to remove the file, you must first delete the LUN. This command is not supported for a Vserver with Infinite Volume.

**Parameters**

- **vserver `<Vserver_Name>`** - Vserver Name
  Specifies the Vserver.

- **{-path `<path>` - LUN Path**
  Specifies the path of the LUN you want to delete. Examples of correct LUN paths are `/vol/vol1/lun1` and `/vol/vol1/qtree1/lun1`.

- **{-volume `<volume_name>` - Volume Name**
  Specifies the volume that contains the LUN you want to delete.

- **{-qtree `<qtree_name>` - Qtree Name**
  Specifies the qtree that contains the LUN you want to delete.
-lun <text> - LUN Name
  Specifies the LUN that you want to delete.

-fforce [-f <true>] - Force Deletion of an Online and Mapped LUN
  Force deletion of an online LUN that is mapped to an initiator group.

-fforce-fenced <true> - Force Deletion of a Fenced LUN
  Force deletion of a LUN that is currently fenced.

Examples

    cluster1::> lun delete -vserver vs1 -path /vol/vol1/lun1

  lun mapping delete on page 195

lun maxsize

Display the maximum possible size of a LUN on a given volume or qtree.

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description

This command returns the maximum size of LUNs for different OS types in a volume or qtree. The command also includes possible maximum size for LUNs with Snapshots or without Snapshots. You can specify the path of the volume or qtree to determine the maximum size of a LUN that you want to create within that volume or qtree.

If you do not specify a path, the command returns the maximum LUN size for each OS type for all volumes and qtrees in a cluster.

The available space in a volume can change over time which means that the size reported by lun maxsize can change as well. In addition, the maximum LUN size allowed in a lun resize command may be less than the size reported by lun maxsize.

Note: This command is not supported for a Vserver with Infinite Volume.

Parameters

{[-fields <fieldname>, ...]
  If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.
  }

[-instance]
  If you specify the -instance parameter, the command displays detailed information about all fields.

[-vserver <Vserver Name>] - Vserver Name
  Specifies the Vserver.

{ [-path <qtree path>] - Volume or Qtree Path
  Specifies the path of the root volume or qtree. Examples of correct LUN paths are /vol/vol1/lun1 and /vol/vol1/qtree1/lun1.
  }

[-volume <volume name>] - Volume Name
  Specifies the volume that contains the LUN you want to get the maximum size for.

[-qtree <qtree name>] - Qtree Name
  Specifies the qtree that contains the LUN you want to get the maximum size for.
-ostype | -t <os_enum_ui> - OS Type

Specifies OS type of the LUN. The OS types are:

- aix - the LUN stores AIX data.
- hpux - the LUN stores HP-UX data.
- hyper_v - the LUN stores Windows Server 2008 or Windows Server 2012 Hyper-V data
- linux - the LUN stores a Linux raw disk without a partition table.
- netware - the LUN stores NetWare data.
- openvms - the LUN stores Open-VMS data
- solaris - the LUN stores Solaris raw disk in a single-slice partition.
- solaris_efi - the LUN stores Solaris_EFI data.
- vmware - the LUN stores VMware data
- windows - the LUN stores a raw disk type in a single-partition Windows disk using the Master Boot Record (MBR) partitioning style.
- windows_gpt - the LUN stores Windows data using the GUID Partition Type (GPT) partitioning style.
- xen - the LUN stores Xen data

-complete-ss-reserve <size> - With Complete Snapshot Reserve

Shows the maximum size possible of a LUN if you have the complete Snapshot reserve enabled.

-ss-reserve <size> - With Snapshot Reserve

Shows the maximum size possible of a LUN if you have the Snapshot reserve enabled.

-without-ss-reserve <size> - Without Snapshot Reserve

Shows the maximum size possible of a LUN if you have no Snapshot reserve enabled.

</table>

Shows the maximum size possible of a LUN for the OS type netware.
lun modify

Modify a LUN

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
This command modifies LUN attributes. Because LUN modifications can result in data corruption or other problems, we recommend that you call technical support if you are unsure of the possible consequences of modifying a LUN.

Note: This command is not supported for a Vserver with Infinite Volume.

Parameters
-vserver <Vserver Name> - Vserver Name
   Specifies the Vserver.

{ -path <path> - LUN Path
   Specifies the path for the LUN you want to modify. Examples of correct LUN paths are /vol/vol1/lun1 and /vol/vol1/qtree1/lun1.

| -volume <volume name> - Volume Name
   Specifies the volume for the LUN you want to modify.

| -qtree <qtree name> - Qtree Name
   Specifies the qtree for the LUN you want to modify.

| -lun <text> - LUN Name
   Specifies the name for the LUN you want to modify. A LUN name is a case-sensitive name and has the following requirements:
   • Must contain one to 255 characters. Spaces are not allowed.
   • Can contain the letters A through Z, a through z, numbers 0 through 9, hyphen (-), underscore (_), right bracket (}), left bracket ({) and period (.).
   • Must start with a letter or number.

[-space-reserve {enabled|disabled}] - Space Reservation
   Specifies whether the space reservation setting is enabled or disabled for a LUN. If you set the parameter to enabled, the LUN is space-reserved. If you set the parameter to disabled, the LUN is non-space reserved. The default is enabled.

{ [-serial <text>] - Serial Number
   Specifies the serial number for the LUN you want to modify.
   The LUN serial number is a twelve-character alphanumeric string containing one or more of the following:
   • upper- and lower-case letters
Some of the characters that are valid in a LUN serial number also have special meaning to the cluster shell command line:

- The question mark (?) activates the command line active help. In order to type a question mark as part of a LUN's serial number, it is necessary to disable active help with the command `set -active-help false`. Active help can later be re-enabled with the command `set -active-help true`.

- The number sign (#) indicates the beginning of a comment to the command line and will cause the remainder of the line to be ignored. To avoid this, enclose the serial number in double quotes (").

Alternatively, the `-serial-hex` parameter can be used to set the LUN serial number specifying the serial number encoded in hexadecimal form.

```
[-serial-hex <Hex String>] - Serial Number (Hex)
```

Specifies the serial number, encoded in hexadecimal form, for the LUN you want to modify. See the description of the `-serial` parameter for additional details.

```
[-comment <text>] - Comment
```

Specifies the comment for the LUN you want to modify.

```
[-space-allocation {enabled|disabled}] - Space Allocation
```

Specifies the new value for the space allocation attribute of the LUN. The space allocation attribute determines if the LUN supports the SCSI Thin Provisioning features defined in the Logical Block Provisioning section of the SCSI SBC-3 standard.

Specifying `enabled` for this parameter enables support for the SCSI Thin Provisioning features.

Specifying `disabled` for this parameter disables support for the SCSI Thin Provisioning features.

Hosts and file systems that do not support SCSI Thin Provisioning should not enable space allocation.

```
[-state {online|offline|nvfail|space-error|foreign-lun-error}] - State
```

Specifies the administrative state of a LUN. The options are:

- **online**
- **offline**

```
[-device-legacy-id <integer>] - Device Legacy ID
```

Specifies the device legacy ID for the LUN you want to modify.

```
[-device-binary-id <text>] - Device Binary ID
```

Specifies the device binary ID for the LUN you want to modify.

```
[-clear-binary-id [true]]] - Clear Device Binary ID
```

Clears the binary format of the optional device ID.

```
[-device-text-id <text>] - Device Text ID
```

Specifies the device text ID for the LUN you want to modify.

```
[-clear-text-id [true]]] - Clear Device Text ID
```

Clears the text format of the optional device ID.

```
[-qos-policy-group <text>] - QoS Policy Group
```

This optionally specifies which QoS policy group to apply to the lun. This policy group defines measurable service level objectives (SLOs) that apply to the storage objects with which the policy group is associated. If you do not assign a policy group to a lun, the system will not monitor and control the traffic to it. To remove this lun from a policy group, enter the reserved keyword "none".

Commands: Manual Page Reference
[-caching-policy <text>] - Caching Policy Name

This optionally specifies the caching policy to apply to the LUN. A caching policy defines how the system caches this volume's data in Flash Cache modules. If a caching policy is not assigned to this LUN, the system uses the caching policy that is assigned to the containing volume or Vserver. If a caching policy is not assigned to the containing volume or Vserver, the system uses the default cluster-wide policy. The available caching policies are:

- none - Does not cache any user data or metadata blocks.
- auto - Read caches all metadata and randomly read user data blocks, and write caches all randomly overwritten user data blocks.
- meta - Read caches only metadata blocks.
- random_read - Read caches all metadata and randomly read user data blocks.
- random_read_write - Read caches all metadata, randomly read and randomly written user data blocks.
- all_read - Read caches all metadata, randomly read and sequentially read user data blocks.
- all_read_random_write - Read caches all metadata, randomly read, sequentially read, and randomly written user data.
- all - Read caches all data blocks read and written. It does not do any write caching.

Default caching-policy is auto.

**Examples**

```bash
cluster1::> lun modify -path /vol/vol1/lun1 -space-reserve disable
```

Disables the space reserve attribute for LUN /vol/vol1/lun1.

```bash
cluster1::> lun modify -path /vol/vol1/lun1 -state offline
```

Takes the LUN /vol/vol1/lun1 offline.

```bash
cluster1::> lun modify -path /vol/vol1/lun1 -comment "new comment"
```

---

**lun move-in-volume**

Move a LUN within a volume

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

**Description**

This command moves a LUN to a new path in the same volume or renames a LUN. If you are organizing LUNs in a qtree, the command moves a LUN from one qtree to another. You can perform a LUN move while the LUN is online and serving data. The process is non-disruptive. Use the `lun move start` command to move a LUN to a different volume within the same Vserver.

**Note:** This command is not supported for a Vserver with Infinite Volume.

**Parameters**

`-vserver <Vserver Name>` - Vserver Name

Specifies the Vserver.
{ -path <path> - LUN Path
    Specifies the path of the LUN you want to move. Examples of correct LUN paths are /vol/vol1/lun1
    and /vol/vol1/qtree1/lun1.
}

| -volume <volume name> - Volume Name
    Specifies the volume of the LUN you want to move.

[-qtree <qtree name>] - Qtree Name
    Specifies the qtree of the LUN you want to move.

-lun <text> - LUN Name
    Specifies the name of the LUN that you want to move.

{ -new-path <path> - New LUN Path
    Specifies the new path of the LUN. Examples of correct LUN paths are /vol/vol1/lun1
    and /vol/vol1/qtree1/lun1.
}

| [-new-qtree <qtree name>] - New Qtree Name
    Specifies the new qtree name that you want to move the LUN to.

-new-lun <text> - New LUN Name
    Specifies the new name of the LUN.

Examples

```
cluster1::> lun move-in-volume -vserver vs1 -volume vol1 -lun lun1 -new-lun newlun1

Renames lun1 to newlun1 on Vserver vs1 and volume vol1.
```

```
cluster1::> lun show -vserver vs1 -volume vol1
Vserver   Path                            State   Mapped   Type         Size
--------- ------------------------------- ------- -------- -------- --------
vs1       /vol/vol1/A/lun1                online  mapped   linux        10MB

cluster1::> lun move-in-volume -vserver vs1 -path /vol/vol1/A/lun1 -new-path /vol/vol1/B/lun1

cluster1::> lun show -vserver vs1 -volume vol1
Vserver   Path                            State   Mapped   Type         Size
--------- ------------------------------- ------- -------- -------- --------
vs1       /vol/vol1/B/lun1                online  mapped   linux        10MB
```

Related references

   lun move start on page 202

lun resize

Changes the size of the LUN to the input value size.

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description

This command resizes a LUN. You can resize a LUN that is mapped and online. However, to prevent any potential problems,
take the LUN offline before resizing it.

When you reduce the size of the LUN, the data in the LUN could be truncated. You will receive an error message if you reduce
the size of the LUN. To avoid this error message, use the force parameter.
When you increase the size of a LUN, the maximum resize size is based on the initial geometry of the LUN and the currently available space in the volume. You will receive an error message if you exceed this limit. The `lun show-instance` command reports the "Maximum Resize Size" for a LUN based on the initial geometry. The `lun maxsize` command reports the maximum LUN size based on the available space. The maximum size of the LUN is the smaller of the two limits issued by the `lun show-instance` command or the `lun maxsize` command.

**Note:** This command is not supported for a Vserver with Infinite Volume.

**Parameters**

- `vserver <Vserver Name>` - Vserver Name
  
  Specifies the Vserver.

- `path <path>` - LUN Path
  
  Specifies the path of the LUN that you want to resize. Examples of correct LUN paths are `/vol/vol1/lun1` and `/vol/vol1/qtree1/lun1`.

- `volume <volume name>` - Volume Name
  
  Specifies the volume that contains the LUN that you want to resize.

- `qtree <qtree name>` - Qtree Name
  
  Specifies the qtree that contains the LUN that you want to resize.

- `lun <text>` - LUN Name
  
  Specifies the LUN name that you want to resize.

- `force | -f [true]` - Force Reduce LUN Size
  
  Overrides any warnings if you are reducing the size of the LUN. If you use this parameter without a value, it is set to true, and the command does not prompt you when reducing the size of a LUN would produce warnings. If you do not use this parameter, the command displays an error if reducing the size of a LUN would create a problem.

- `size <size>` - New Size
  
  Specifies the new size of the LUN.
  
  - c (1 byte)
  - w (2 bytes)
  - B (512 bytes)
  - k (1024 bytes)
  - M (k*k bytes)
  - G (k*m bytes)
  - T (m*m bytes)

**Examples**

```
cluster1::> lun resize -vserver vs1 -path /vol/vol1/lun1 -size 500M -force
```

Resizes LUN `/vol/vol1/lun1` on Vserver `vs1` to 500M, overriding all warnings.
cluster1::> lun resize -vserver vs1 -path /vol/vol1/lun1 -size +5m
Adds 5M of space to LUN /vol/vol1/lun1 for a total of 15MB.

cluster1::> lun resize -vserver vs1 -path /vol/vol1/lun1 -size -10m
Error: command failed: Reducing LUN size without coordination with the host system may cause permanent data loss or corruption. Use the force flag to allow LUN size reduction.

Related references

lun show

Display a list of LUNs

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The command displays information for LUNs. Use the instance parameter to display additional LUN details, such as serial number and space-reservation settings.

Parameters

{-fields <fieldname>,...}
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use -fields ? to display the fields to specify.

{-instance}
If you specify the -instance parameter, the command displays detailed information about all fields.

-vserver <Vserver Name> - Vserver Name
Selects the LUNs that match this parameter value.

{-path <path>} - LUN Path
Selects the LUNs that match this parameter value. Examples of correct LUN paths are /vol/vol1/lun1 and /vol/vol1/qtree1/lun1

{-volume <volume name>} - Volume Name
Selects the LUNs that match this parameter value.

{-qtree <qtree name>} - Qtree Name
Selects the LUNs that match this parameter value.
[-lun <text>] - LUN Name
Selects the LUNs that match this parameter value.

[-size | -s <size>] - LUN Size
Selects the LUNs that match this parameter value.

[-prefix-size | -P <size>] - Prefix Size (privilege: advanced)
Selects the LUNs that match the prefix stream size that you specify.

[-ostype | -t <os_enum>] - OS Type
Selects the LUNs that match this parameter value. The operating system types are:
- aix - the LUN stores AIX data.
- hpux - the LUN stores HP-UX data.
- hyper_v - the LUN stores Windows Server 2008 or Windows Server 2012 Hyper-V data
- linux - the LUN stores a Linux raw disk without a partition table.
- netware - the LUN stores NetWare data.
- openvms - the LUN stores Open-VMS data
- solaris - the LUN stores Solaris raw disk in a single-slice partition.
- solaris_efi - the LUN stores Solaris_EFI data.
- vmware - the LUN stores VMware data
- windows - the LUN stores a raw disk type in a single-partition Windows disk using the Master Boot Record (MBR) partitioning style.
- windows_gpt - the LUN stores Windows data using the GUID Partition Type (GPT) partitioning style.
- xen - the LUN stores Xen data

[-space-reserve {enabled|disabled}] - Space Reservation
Selects the LUNs that match this parameter value. A value of enabled selects LUN that are space-reserved. A value of disabled select LUNs that are non-space reserved.

[-serial <text>] - Serial Number
Selects the LUNs that match this parameter value.
The LUN serial number is a twelve-character alphanumeric string containing one or more of the following:
- upper- and lower-case letters
- numbers
- the characters: &<, >, /, #, $, %, *, =, ?, @, [, ], ^, ~
Some of the characters that are valid in a LUN serial number also have special meaning to the cluster shell command:
- The question mark (?) activates the command line active help. In order to type a question mark as part of a LUN's serial number, it is necessary to disable active help with the command set -active-help false. Active help can later be re-enabled with the command set -active-help true.
- The number sign (#) indicates the beginning of a comment to the command line and will cause the remainder of the line to be ignored. To avoid this, enclose the serial number in double quotes (").
The less than (<), greater than (>), asterisk (*), and exclamation point (!) influence the query behavior of the command. To use these as characters in a LUN's serial query, you must first press escape (ESC). To use these characters to influence the query, enclose the serial number, or partial serial number, in double quotes (“”) and apply <, >, *, or !, outside of the double quotes.

Alternatively, the -serial-hex parameter can be used to select LUNs using the serial number encoded in hexadecimal form.

```
[-serial-hex <Hex String>] - Serial Number (Hex)
Selects the LUNs that match this parameter value. This parameter applies to the LUN serial number encoded in hexadecimal form. See the description of the -serial parameter for additional details.
```

```
[-comment <text>] - Comment
Selects the LUNs that match this parameter value.
```

```
[-space-reserve-honored {true|false}] - Space Reservations Honored
Selects the LUNs that match this parameter value. A value of true select LUNs that have their space reservation honored by the container volume. A value of false displays the LUNs that are non-space reserved.
```

```
[-space-allocation {enabled|disabled}] - Space Allocation
Selects the LUNs that match this parameter value. The space allocation attribute determines if the LUN supports the SCSI Thin Provisioning features defined in the Logical Block Provisioning section of the SCSI SBC-3 standard.

Specifying enabled for this parameter selects LUNs with support enabled for the SCSI Thin Provisioning features.

Specifying disabled for this parameter selects LUNs with support disabled for the SCSI Thin Provisioning features.

Hosts and file systems that do not support SCSI Thin Provisioning should not enable space allocation.
```

```
[-state {online|offline|nvfail|space-error|foreign-lun-error}] - State
Selects the LUNs that match this parameter value. The states are:

- online- the LUN is online.
- offline- the LUN is administratively offline, or a more detailed offline reason is not available.
- foreign-lun-error- the LUN has been automatically taken offline due to a media error on the associated foreign LUN.
- nvfail- the LUN has been automatically taken offline due to an NVRAM failure.
- space-error- the LUN has been automatically taken offline due to insufficient space.
```

```
[-uuid <UUID>] - LUN UUID
Selects the LUNs that match this parameter value.
```

```
[-mapped {mapped|unmapped}] - Mapped
Selects the LUNs that match this parameter value. A value of mapped selects the LUNs that are mapped to an initiator group.
```

```
[-block-size <size>] - Block Size
Selects the LUNs that match this parameter value.
```

```
[-device-legacy-id <integer>] - Device Legacy ID
Selects the LUNs that match this parameter value.
```
[-device-binary-id <text>] - Device Binary ID
Selects the LUNs that match this parameter value.

[-device-text-id <text>] - Device Text ID
Selects the LUNs that match this parameter value.

[-read-only {true|false}] - Read Only
Selects the LUNs that match this parameter value.

[-restore-inaccessible {true|false}] - Fenced Due to Restore
Selects the LUNs that match the state you specify. A value of true means that a LUN is fenced for I/O and management due to a restore operation.

[-size-used <size>] - Used Size
Selects the LUNs that match this parameter value.

[-max-resize-size <size>] - Maximum Resize Size
Selects the LUNs that match this parameter value.

[-creation-timestamp <MM/DD/YYYY HH:MM:SS>] - Creation Time
Selects the LUNs that match this parameter value.

[-class {regular|protocol-endpoint|vvol}] - Class
Selects the LUNs that match this parameter value.

[-node <nodename>] - Node Hosting the LUN
Selects the LUNs that match this parameter value.

[-qos-policy-group <text>] - QoS Policy Group
Selects the LUNs that match this parameter value.

A policy group defines measurable service level objectives (SLOs) that apply to the storage objects with which the policy group is associated. If you do not assign a policy group to a lun, the system will not monitor and control the traffic to it.

[-caching-policy <text>] - Caching Policy Name
Display the LUNs that match the specified cache.

A caching policy defines the caching behavior of this LUN at the Flash Cache level. If a caching policy is not assigned to this LUN, the system uses the caching policy that is assigned to the containing volume or Vserver. If a caching policy is not assigned to the containing volume or Vserver, the system uses the default cluster-wide policy. The available caching policies are:

- none - Does not cache any user data or metadata blocks.
- auto - Read caches all metadata and randomly read user data blocks, and write caches all randomly overwritten user data blocks.
- meta - Read caches only metadata blocks.
- random_read - Read caches all metadata and randomly read user data blocks.
- random_read_write - Read caches all metadata, randomly read and randomly written user data blocks.
- all_read - Read caches all metadata, randomly read and sequentially read user data blocks.
- all_read_random_write - Read caches all metadata, randomly read, sequentially read, and randomly written user data.
- all - Read caches all data blocks read and written. It does not do any write caching.

Default caching-policy is auto.
[-is-clone {true|false}] - Clone
Selects the LUNs that match this parameter value.

[-is-clone-autodelete-enabled {true|false}] - Clone Autodelete Enabled
Selects the LUNs that match this parameter value.

[-inconsistent-import {true|false}] - Inconsistent Import
Selects the LUNs that match this parameter value. A value of true means that the import of this LUN is incomplete.

[-serial-7-mode <text>] - 7-mode Serial Number (privilege: advanced)
Selects the LUNs that match this parameter value.
LUNs transitioned from Data ONTAP 7-Mode are assigned new serial numbers for use with Clustered Data ONTAP. The original 7-Mode serial number is displayed in this field for reference.

**Examples**

```shell
cluster1::> lun show -vserver vs0 -path /vol/vol1/lun1 -instance
Vserver Name: vs0
LUN Path: /vol/vol1/lun1
Volume Name: vol1
Qtree Name: ""
LUN Name: lun1
LUN Size: 10MB
OS Type: linux
Space Reservation: disable
Serial Number: 1k/wc+9Cpb1s
Comment: new comment
Space Reservations Honored: true
Space Allocation: disable
State: offline
LUN UUID: 6435dcaa-e360-11df-aa84-00a0980cb0eb
Mapped: unmapped
Block Size: 512.00B
Device Legacy ID: -
Device Binary ID: -
Device Text ID: -
Read Only: false
Used Size: 0.00B
```

The example above displays details of the LUN at path /vol/vol1/lun1 in Vserver vs0.

```shell
cluster1::> lun show -serial 1k/wc+9Cpb1s
Vserver Path State Mapped Type Size
-------- ------------- ------- -------- --------
vs1 /vol/vol1/lun1 offline mapped linux 10MB
```

The example above displays information for the LUN with serial number 1k/wc+9Cpb1s.

```shell
cluster1::> lun show -vserver vs1 -volume vol1
Vserver Path State Mapped Type Size
-------- ------------- ------- -------- --------
vs1 /vol/vol1/lun1 offline mapped linux 10MB
vs1 /vol/vol1/lun2 online mapped windows 47.07MB
2 entries were displayed.
```

**Manage Lun Copy Operations**

Manage LUN copy operations
**lun copy cancel**

Cancel a LUN copy operation before the new LUN has been created

**Availability:** This command is available to cluster and Vserver administrators at the advanced privilege level.

**Description**
The lun copy cancel command cancels an ongoing LUN copy operation prior to creation of the new LUN. The command fails if the LUN already exists at the destination path; in that case, use the lun delete command to delete the LUN at the destination path.

All data transfers will be halted.

**Note:** This is an advanced command because the preferred way to cancel a LUN copy operation is to wait until the new LUN becomes visible, and then use the lun delete command to delete the LUN.

**Note:** LUNs cannot be copied to or from a Vserver with Infinite Volume.

**Parameters**

\{-vserver <Vserver Name> - Vserver Name\}

Specifies the name of the Vserver that will host the destination LUN.

\{-destination-path <path> - Destination Path\}

Specifies the full path to the new LUN, in the format /vol/<volume>/[<qtree>]/<lun>.

**Examples**

```
cluster1::*> lun copy cancel -vserver vs1 -destination-path /vol/vol2/lun2
```

**Related references**

*lun delete* on page 156

---

**lun copy modify**

Modify an ongoing LUN copy operation

**Availability:** This command is available to cluster and Vserver administrators at the admin privilege level.

**Description**
The lun copy modify command modifies the maximum throughput of an ongoing copy operation.

**Note:** LUNs cannot be copied to or from a Vserver with Infinite Volume.

**Parameters**

\{-vserver <Vserver Name> - Vserver Name\}

Specifies the name of the Vserver that will host the destination LUN.

\{-destination-path <path> - Destination Path\}

Specifies the full path to the new LUN, in the format /vol/<volume>/[<qtree>]/<lun>.

\{-max-throughput <integer>[KB|MB|GB|TB|PB] - Maximum Transfer Rate (per sec)\}

Specifies the maximum amount of data, in bytes, that can be transferred per second in support of this operation. This mechanism can be used to throttle a transfer, to reduce its impact on the performance of the source and destination nodes.
Note: The specified value will be rounded up to the nearest megabyte.

Examples

```bash
cluster1::> lun copy modify -vserver vs1 -destination-path /vol/vol2/lun2 -max-throughput 25MB
```

### lun copy pause

Pause an ongoing LUN copy operation

**Availability:** This command is available to cluster and Vserver administrators at the admin privilege level.

**Description**
The `lun copy pause` command pauses an ongoing copy operation. Use the `lun copy resume` command to resume the copy operation.

**Note:** LUNs cannot be copied to or from a Vserver with Infinite Volume.

**Parameters**

- `-vserver <Vserver Name>` - Vserver Name
  
  Specifies the name of the Vserver that will host the destination LUN.

- `-destination-path <path>` - Destination Path
  
  Specifies the full path to the new LUN, in the format `/vol/<volume>[/<qtree>]/<lun>`.

Examples

```
cluster1::> lun copy pause -vserver vs1 -destination-path /vol/vol2/lun2
```

**Related references**

- `lun copy resume` on page 170

### lun copy resume

Resume a paused LUN copy operation

**Availability:** This command is available to cluster and Vserver administrators at the admin privilege level.

**Description**
The `lun copy resume` command resumes a paused copy operation.

**Note:** LUNs cannot be copied to or from a Vserver with Infinite Volume.

**Parameters**

- `-vserver <Vserver Name>` - Vserver Name
  
  Specifies the name of the Vserver that will host the destination LUN.

- `-destination-path <path>` - Destination Path
  
  Specifies the full path to the new LUN, in the format `/vol/<volume>[/<qtree>]/<lun>`.
Examples

```
cluster1::> lun copy resume -vserver vs1 -destination-path /vol/vol2/lun2
```

**lun copy show**

Display a list of LUNs currently being copied.

**Availability**: This command is available to cluster and Vserver administrators at the admin privilege level.

**Description**

The `lun copy show` command shows information about LUNs currently being copied in the cluster.

**Note**: This command is not supported for a Vserver with Infinite Volume.

**Parameters**

```{[-fields <fieldname>, ...]  
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

| [-instance]  
If you specify the -instance parameter, the command displays detailed information about all fields.

[-vserver <Vserver Name>] - Destination Vserver Name
Selects LUN copy operations that match this parameter value.

[-destination-path <path>] - Destination Path
Selects LUN copy operations that match this parameter value.

[-source-vserver <vserver name>] - Source Vserver Name
Selects LUN copy operations that match this parameter value.

[-source-path <path>] - Source Path
Selects LUN copy operations that match this parameter value.

[-source-snapshot <snapshot name>] - Source Snapshot Name
Selects LUN copy operations that match this parameter value.

[-is-promoted-early {true|false}] - Is Destination Promoted Early
Selects LUN copy operations that match this parameter value.

[-max-throughput {<integer>[KB|MB|GB|TB|PB]}] - Maximum Transfer Rate (per sec)
Selects LUN copy operations that match this parameter value.

[-job-status {Preparing|Allocation-Map|Data|Destroying|Paused-Admin|Paused-Error|Complete|Destroyed}] - LUN Copy Status
Selects LUN copy operations that match this parameter value. The possible values are:

- **Preparing** - the LUN copy job is in Preparing status.
- **Allocation-Map** - the LUN copy job is in Allocating status.
- **Data** - the LUN copy job is in Moving Data status.
• **Destroying** - the LUN copy job is in Destroying status.

• **Paused-Admin** - the LUN copy job is in Paused By Admin status.

• **Paused-Error** - the LUN copy job is in Paused By Error status.

• **Complete** - the LUN copy job is in Complete status.

• **Destroyed** - the LUN copy job is in Destroyed status.

Syntax:

```
[-progress-percent <percent>] - LUN Copy Progress (%)
```

Selects LUN copy operations that match this parameter value.

```
[-elapsed-time <time_interval>] - Elapsed Time
```

Selects LUN copy operations that match this parameter value.

```
[-cutover-time <time_interval>] - Cutover Time
```

Selects LUN copy operations that match this parameter value.

```
[-is-snapshot-fenced {true|false}] - Is Snapshot Fenced
```

Selects LUN copy operations that match this parameter value.

```
[-is-destination-ready {true|false}] - Is Destination Ready
```

Selects LUN copy operations that match this parameter value.

```
[-last-failure-reason <text>] - Last Failure Reason
```

Selects LUN copy operations that match this parameter value.

### Examples

```
cluster1::> lun copy show
Vserver  Destination Path                Status          Progress
--------- ------------------------------- --------------- --------
vs1       /vol/vol2/lun1                  Data            35%
vs1       /vol/vol2/lun2                  Complete        100%
2 entries were displayed.
```

The example above displays information about all the LUN copy operations in the cluster.

```
cluster1::> lun copy show -vserver vs1 -destination-path /vol/vol2/lun1 -instance

Destination Vserver Name: vs1
Destination Path: /vol/vol2/lun1
Source Vserver Name: vs1
Source Path: /vol/vol1/lun1
Source Snapshot Name: -
Is Destination Promoted Early: false
Maximum Transfer Rate (per sec): 0B
LUN Copy Status: Data
LUN Copy Progress (%): 35%
Elapsed Time: 145s
Cutover Time (secs): 0s
Is Snapshot Fenced: true
Is Destination Ready: true
Last Failure Reason: -
```

### lun copy start

Start copying a LUN from one volume to another within a cluster

**Availability:** This command is available to cluster and Vserver administrators at the admin privilege level.
Description

The `lun copy start` command initiates copying of a LUN from one volume to another. The destination volume can be located in the same Vserver as the source volume (intra-Vserver copy) or in a different Vserver (inter-Vserver).

**Note:** LUNs cannot be copied to or from a Vserver with Infinite Volume.

**Note:** A cluster administrator must first create a Vserver peering relationship using `vserver peer create` before initiating an inter-Vserver LUN copy operation.

Parameters

- `-vserver <Vserver Name>` - Destination Vserver Name
  Specifies the name of the Vserver that will host the new LUN.

- `-destination-path <path>` - Destination Path
  Specifies the full path to the new LUN, in the format `/vol/<volume>[/<qtree>]/<lun>`.

- `-source-path <path>` - Source Path
  Specifies the full path to the source LUN, in the format `/vol/<volume>[/.snapshot/<snapshot>][/<qtree>]/<lun>`.

- `-source-vserver <vserver name>` - Source Vserver Name
  Optionally specifies the name of the Vserver hosting the LUN to be copied.

  If this parameter is not specified, it is assumed that an intra-Vserver copy operation is being initiated. The source volume is expected to be in the same Vserver as the destination volume.

- `-promote-early [true]` - Promote Early
  Optionally specifies that the destination LUN needs to be promoted early.

  If the destination is promoted early, the new LUN will be visible immediately. However, Snapshot copies of the volume containing the new LUN cannot be taken until the LUN copy operation reaches 'Moving Data' status.

  If the destination is promoted late, the new LUN will be visible only after it has been fully framed. However, the LUN copy job will not block the creation of Snapshot copies of the volume containing the new LUN.

  If this parameter is not specified, the destination LUN will be promoted late.

- `-max-throughput <integer>[KB|MB|GB|TB|PB]` - Maximum Transfer Rate (per sec)
  Optionally specifies the maximum amount of data, in bytes, that can be transferred per second in support of this operation. This mechanism can be used to throttle a transfer, to reduce its impact on the performance of the source and destination nodes.

  If this parameter is not specified, throttling is not applied to the data transfer.

  **Note:** The specified value will be rounded up to the nearest megabyte.

Examples

```
cluster1::> lun copy start -vserver vs2 -destination-path /vol/vol2/lun2 -source-path /vol/vol1/lun1

Starts an inter-Vserver copy of LUN `lun1` from volume `vol1` in Vserver `vs1` to `lun2` on volume `vol2` in Vserver `vs2`.

cluster1::> lun copy start -vserver vs1 -destination-path /vol/vol2/lun2 -source-path /vol/vol1/lun1

Starts an intra-Vserver copy of LUN `lun1` from volume `vol1` in Vserver `vs1` to `lun2` on volume `vol2` in Vserver `vs1`.

**lun bind commands**

The bind directory

*Note:* These commands are not supported for a Vserver with Infinite Volume.

**lun bind create**

Bind a VVol LUN to a protocol endpoint

**Availability:** This command is available to cluster and Vserver administrators at the advanced privilege level.

**Description**

This command creates a new binding between a protocol endpoint and a vvol LUN. If a binding between the specified endpoint and vvol already exists, the reference count for the binding is incremented by one.

*Note:* For optimal results, the protocol endpoint and vvol must be hosted by the same node in the cluster.

*Note:* This command is not supported for a Vserver with Infinite Volume.

**Parameters**

- `-vserver <Vserver Name>` - *Vserver name*
  
  Specifies the name of the Vserver.

- `-protocol-endpoint-path <path>` - *Protocol Endpoint*
  
  Specifies the path to the protocol endpoint. The specified LUN must already exist and be of class "protocol-endpoint". Examples of correct LUN paths are `/vol/vol1/lun1` and `/vol/vol1/qtree1/lun1`.

- `-vvol-path <path>` - *VVol Path*
  
  Specifies the path to the vvol. The specified LUN must already exist and be of the class "vvol". Examples of correct LUN paths are `/vol/vol1/lun1` and `/vol/vol1/qtree1/lun1`.

**Examples**

```
cluster1::*> lun bind create -vserver vs1 -protocol-endpoint-path /vol/VV1/PE1 -vvol-path /vol/VV3/234ace
```
**lun bind destroy**

Unbind a VVol LUN from a protocol endpoint

**Availability:** This command is available to cluster and Vserver administrators at the advanced privilege level.

**Description**
Decrement the reference count of the binding between a protocol endpoint and vvol LUN. If the resulting reference count is zero, the binding is removed.

**Note:** This command is not supported for a Vserver with Infinite Volume.

**Parameters**

- `-vserver <Vserver Name>` - Vserver name
  Specifies the Vserver.

- `-protocol-endpoint-path <path>` - Protocol Endpoint
  Specifies the path of the protocol endpoint LUN. Examples of correct LUN paths are /vol/vol1/lun1 and /vol/vol1/qtree1/lun1.

- `-vvol-path <path>` - VVol Path
  Specifies the path of the vvol LUN. Examples of correct LUN paths are /vol/vol1/lun1 and /vol/vol1/qtree1/lun1.

- `[-force [true]]` - If true, unbind the Vvol completely even if the current reference count is greater than 1. The default is false.
  Completely remove the specified binding, regardless of the current reference count.

**Examples**

```bash
cluster1::*> lun bind destroy -protocol-endpoint-path /vol/VV2/PE2 -vvol-path /vol/VV2/30dfab -vserver vs1
```

**lun bind show**

Show list of Vvol bindings

**Availability:** This command is available to cluster and Vserver administrators at the advanced privilege level.

**Description**
Shows the configured VVol to protocol endpoint bindings.

**Note:** This command is not supported for a Vserver with Infinite Volume.

**Parameters**

```bash
{-fields <fieldname>, ...}
```

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

```bash
[-instance]
```

If you specify the `-instance` parameter, the command displays detailed information about all fields.

- `-vserver <Vserver Name>` - Vserver Name
  Selects the bindings that match this parameter value.
[-protocol-endpoint-msid <integer>] - PE MSID
Selects the bindings that match this parameter value.

[-protocol-endpoint-vdisk-id <text>] - PE Vdisk ID
Selects the bindings that match this parameter value.

[-vvol-msid <integer>] - VVol MSID
Selects the bindings that match this parameter value.

[-vvol-vdisk-id <text>] - VVol Vdisk ID
Selects the bindings that match this parameter value.

[-vserver-uuid <UUID>] - Vserver UUID
Selects the bindings that match this parameter value.

[-protocol-endpoint-path <path>] - Protocol Endpoint
Selects the bindings that match this parameter value. Examples of correct LUN paths are /vol/vol1/lun1 and /vol/vol1/qtree1/lun1.

[-protocol-endpoint-node <nodename>] - PE Node
Selects the bindings that match this parameter value.

[-vvol-path <path>] - VVol
Selects the bindings that match this parameter value. Examples of correct LUN paths are /vol/vol1/lun1 and /vol/vol1/qtree1/lun1.

[-vvol-node <nodename>] - VVol Node
Selects the bindings that match this parameter value.

[-secondary-lun <Hex 64bit Integer>] - Secondary LUN
Selects the bindings that match this parameter value.

[-is-optimal {true|false}] - Optimal binding
Selects the bindings that match this parameter value.

[-reference-count <integer>] - Reference Count
Selects the bindings that match this parameter value.

Examples

```
cluster1::*> lun bind show -vserver vs1
Vserver   Protocol Endpoint       Node           Secondary LUN  Optimal?
---------- -------------------------------------- -------------- --------
vs1       /vol/VV1/PE1               cluster-node1    d200000010000 false
          /vol/VV2/30dfab             vs1            d200000020000 true
          /vol/VV3/234ace             vs1            d200000030000 true
          /vol/VV1/234acf             vs1            d200000010000 true
          /vol/VV2/PE2                cluster-node2    d200000010000 true
          /vol/VV2/30dfab             vs1            d200000010000 true
4 entries were displayed.
```

lun igroup commands
Manage initiator groups
lun igroup add

Add initiators to an initiator group

**Availability:** This command is available to cluster and Vserver administrators at the admin privilege level.

**Description**

This command adds initiators to an existing initiator group (igroup). You can add an initiator to an initiator group only if there are no LUN mapping conflicts. Mapping conflicts occur when an initiator is already paired with a LUN. If you attempt to run this command and there are LUN mapping conflicts, the command returns an error.

An initiator cannot be a member of two igroups of different OS types. For example, if you have an initiator that belongs to a Solaris igroup, the command does not allow you to add this initiator to an AIX igroup.

When you add FCP initiators, you can specify an alias instead of the initiator's World Wide Port Name (WWPN) or the iSCSI Qualified name (IQN).

**Note:** This command is not supported for a Vserver with Infinite Volume.

**Parameters**

- `-vserver <Vserver Name>` - Vserver Name
  
  Specifies the Vserver.

- `-igroup <text>` - Igroup Name
  
  Specifies the initiator group to which you want to add a new initiator.

- `-initiator <text>, ...` - Initiators
  
  Specifies the initiator that you want to add. You can specify the WWPN, IQN, or alias of the initiator.

**Examples**

```
cluster1::> lun igroup add -vserver vs1 -igroup ig1 -initiator iqn.1992-08.com.mv.mvinitiator
```

lun igroup bind

Bind an existing initiator group to a given portset

**Availability:** This command is available to cluster and Vserver administrators at the admin privilege level.

**Description**

This command binds an initiator group to a port set so the host knows which LIFs or TPGs to access. When you bind a port set to an igroup, the host knows which iSCSI or FCP LIF to access. If you do not bind an igroup to a port set, and you map a LUN to the igroup, then the initiators in the igroup can access the LUN on any port on the Vserver.

The initiator group cannot be bound to another port set when you use this command. If you attempt to bind a port set to an initiator group that is already bound to an existing port set, the command returns an error. You can only bind an initiator group to one port set at a time.

If the initiator group is bound, use the `lun igroup unbind` command to unbind the initiator group from the port set. After the initiator group is unbound, you can bind it to another port set.

**Note:** This command is not supported for a Vserver with Infinite Volume.
Parameters

-vserver <Vserver Name> - Vserver Name
   Specifies the Vserver.

-igroup <text> - Igroup Name
   Specifies the initiator group that you want to bind a port set to.

-portset <text> - Portset Binding Igroup
   Specifies the port set name that you want to bind an initiator group to.

Examples

cluster1::> lun igroup bind -vserver vs1 -igroup ig1 -portset-name ps1

Related references

   lun igroup unbind on page 184

lun igroup create

Create a new initiator group

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description

This command creates a new initiator group (igroup). Use igroups to control which hosts have access to specific LUNs. When you bind an igroup to a port set, a host in the igroup can access the LUNs only by connecting to the target ports in the port set.

When you create an igroup, you can add multiple existing initiators by specifying them in a list, separating them with commas. Later, you can add or remove initiators from the initiator group. Use the lun igroup add command to add initiators. Use the lun igroup remove command to remove an initiator. Unless the -initiator option is supplied, no initiators are added to a new igroup.

You can also bind a port set to an initiator when you create an initiator group. You can modify the port set binding of an initiator group by using the lun igroup bind command or the lun igroup unbind command.

The name you assign to an igroup is independent of the name of the host that is used by the host operating system, host files, or Domain Name Service (DNS). If you name an igroup aix1, for example, it is not mapped to the actual IP host name (DNS name) of the host.

Note: This command is not supported for a Vserver with Infinite Volume.

Parameters

-vserver <Vserver Name> - Vserver Name
   Specifies the Vserver.

-igroup <text> - Igroup Name
   Specifies the name of the new initiator group. An initiator group name is a case-sensitive name that must contain one to 96 characters. Spaces are not allowed.

   Note: It might be useful to provide meaningful names for igroups, ones that describe the hosts that can access the LUNs mapped to them.

{ [-protocol <protocol_enum>] - Protocol
   Specifies if the initiator group protocol is fcp, iscsi, or mixed.

   | [-fcp | -f [true]] - FCP
   Specifies FCP as the protocol type of the new igroup.
|-iscsi |-i [true]] - iSCSI

Specifies iSCSI as the protocol type of the new igroup.

-ostype | t {solaris|windows|hpux|aix|linux|netware|vmware|openvms|xen|hyper_v} - OS Type

Specifies the operating system type for the new initiator group. The operating system type indicates the type of host operating system used by all of the initiators in the igroup. All initiators in an igroup must be of the same operating system type. The operating system types of initiators are

- solaris
- windows
- hpux
- aix
- linux
- netware
- vmware
- openvms
- xen
- hyper_v

[portset |-a <text>] - Portset Binding Igroup

Specifies that a port set is bound to the initiator.

-initiator <text>, ... - Initiators

Specifies the initiators that are attached to the new initiator group. By default, no initiators are added to the new igroup.

Examples

```
cluster1::> lun igroup create -vserver vs1 -igroup ig1 -protocol mixed -ostype linux -initiator iqn.2001-04.com.example:abc123
```

lun igroup delete

Delete an initiator group

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description

This command deletes an existing initiator group. By default, you cannot delete an initiator group if LUN maps for that initiator group exist. You need to unmap all the LUNs that are associated with that initiator group before you can delete the initiator group. Use the lun unmap command to remove LUNS from an initiator group.

You can specify the force option to delete an initiator group and remove existing LUN maps defined for that initiator group.
Note: This command is not supported for a Vserver with Infinite Volume.

Parameters
-vserver <Vserver Name> - Vserver Name
   Specifies the Vserver.
-igroup <text> - Igroup Name
   Specifies the initiator group that you want to delete.
[-force | -f [true]] - Force
   Deletes an initiator group and all associated LUN maps.

Examples
cluster1::> lun igroup delete -vserver vs1 -igroup ig1

Related references
lun mapping delete on page 195

lun igroup disable-aix-support
Disables SAN AIX support on the cluster
Availability: This command is available to cluster and Vserver administrators at the advanced privilege level.

Description
This command disables the SAN AIX support across the cluster (all Vservers and all AIX initiator groups). However, before you can disable SAN AIX support, you must remove all SAN AIX related objects from the cluster. You need to unmap all the LUNs that are associated with the AIX initiator groups. Then you need to delete all of the AIX initiator groups. Use the lun unmap command to remove LUNS from an initiator group. Use the igroup delete command to delete an initiator group.

Note: This command is not intended to be used in normal operation. Use only when you are downgrading to a release that does not support SAN AIX operation.

Examples
cluster1::> lun igroup disable-aix-support

Related references
lun mapping delete on page 195

lun igroup modify
Modify an existing initiator group
Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
This command modifies an attribute for an initiator group. Currently, the only settable attribute is the operating system.

Note: This command is not supported for a Vserver with Infinite Volume.
Parameters

-vserver <Vserver Name> - Vserver Name
  Specifies the Vserver.

-igroup <text> - Igroup Name
  Specifies the initiator group whose attribute you want to modify.

[-ostype | -t {solaris|windows|hpux|aix|linux|netware|vmware|openvms|xen|hyper_v}] - OS Type
  Specifies the operating system that you want to modify. The operating system types of initiators are
  • solaris
  • windows
  • hpux
  • aix
  • linux
  • netware
  • vmware
  • openvms
  • xen
  • hyper_v

Examples

cluster1::> lun igroup modify -vserver vs1 -igroup ig1 -ostype windows

lun igroup remove

Remove initiators from an initiator group

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
This command removes an initiator from an initiator group. You can only remove an initiator if no existing LUN maps are defined for that initiator group. You must unmap the LUNs from the initiator group with the lun unmap command before you can remove initiators from the initiator group.

You can use the force option to remove an initiator and associated LUN maps.

Note: This command is not supported for a Vserver with Infinite Volume.

Parameters

-vserver <Vserver Name> - Vserver Name
  Specifies the Vserver.

-igroup <text> - Igroup Name
  Specifies the initiator group from which you want to remove an initiator.

-initiator <text>, ... - Initiators
  Specifies the initiator name you want to remove. Use the WWPN, IQN or the alias of the initiator.
[-force | -f [true]] - Force
Forcibly removes an initiator and any associated LUN maps.

Examples

```
cluster1::> lun igroup remove -vserver vs1 -igroup ig1 -initiator iqn.1992-08.com.mv.mvinitiator
```

Related references

lun mapping delete on page 195

lun igroup rename

Rename an existing initiator group

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description

This command renames an existing initiator group. When you rename an initiator group, this action does not affect access to the LUNs mapped to the initiator group you want to rename.

An initiator group name is a case-sensitive name and must meet the following requirements:

- Must contain one to 96 characters. Spaces are not allowed.
- Can contain the letters A through Z, a through z, numbers 0 through 9, hyphen (-), underscore (_), colon (:), and period (.)
- Must start with a letter or number.

Note: This command is not supported for a Vserver with Infinite Volume.

Parameters

-vserver <Vserver Name> - Vserver Name

Specifies the Vserver.

-igroup <text> - Igroup Name

Specifies the initiator group you want to rename.

-new-name <text> - New Igroup Name

Specifies the new name of the initiator group.

Examples

```
cluster1::> lun igroup rename -vserver vs1 -igroup ig1 -new-name ignew1
```

lun igroup show

Display a list of initiator groups

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description

This command displays status information for initiator groups (igroup). By default, the command displays status for all initiator groups.
Parameters

\{[-fields <fieldname>, ...]

If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use -fields ? to display the fields to specify.

\{-instance \}

If you specify the -instance parameter, the command displays detailed information about all fields.

\{-vserver <Vserver Name>\} - Vserver Name

Specifies the Vserver.

\{-igroup <text>\} - Igroup Name

Selects the initiator groups that match this parameter value.

\{-protocol <protocol_enum>\} - Protocol

Selects the initiator groups that match this parameter value (FCP, iSCSI, or mixed).

\{-ostype | -t {solaris|windows|hpux|aix|linux|netware|vmware|openvms|xen|hyper_v}\} - OS Type

Selects the initiator groups that match this parameter value. The operating system types are

- solaris
- windows
- hpux
- aix
- linux
- netware
- vmware
- openvms
- xen
- hyper_v

\{-portset | -a <text>\} - Portset Binding Igroup

Selects the initiator groups that match this parameter value.

\{-initiator <text>, ...\} - Initiators

Selects the initiator groups that match this parameter value.

\{-uuid <UUID>\} - Igroup UUID

Selects the initiator groups that match this parameter value.

Examples

cluster1::> igroup show -instance
Vserver Name: vs0
Igroup Name: ig1
  Protocol: mixed
  OS Type: linux
Portset Binding Igroup: -
  Igroup UUID: 358338ba-cfd6-11df-a9ab-123478563412
  Initiators: iqn.1992-08.com.mv:abc (not logged in)

Vserver Name: vs0
Igroup Name: ig2
  Protocol: mixed
  OS Type: linux
Portset Binding Igroup: -
  Igroup UUID: 3fb136c7-cfd6-11df-a9ab-123478563412
  Initiators: -
  Vserver Name: vs1
  Igroup Name: ig2
  Protocol: mixed
  OS Type: windows
Portset Binding Igroup: p1
  Igroup UUID: 03accf6b-d08c-11df-a9ab-123478563412
  Initiators: -
3 entries were displayed.

lun igroup unbind

Unbind an existing initiator group from a portset

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
This command unbinds an initiator group from a port set. When you unbind an initiator group from a port set, all of the initiators in the initiator group have access to all target LUNs on all network interfaces.

Note: This command is not supported for a Vserver with Infinite Volume.

Parameters
-vserver <Vserver Name> - Vserver Name
  Specifies the Vserver.
-igroup <text> - Igroup Name
  Specifies the initiator group that you want to unbind from the port set.

Examples
  cluster1::> lun igroup unbind -vserver vs1 -igroup ig2

lun import commands

Manage Foreign LUN Import

Note: These commands are not supported for a Vserver with Infinite Volume.

lun import create

Create an import relationship

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
This command creates an import relationship between a specified LUN and a specified foreign disk so you can import the foreign disk data into a LUN.

The foreign disk must be marked as foreign using storage disk set-foreign-lun command before you can begin the import progress.

The LUN must be of the same size as the foreign disk.
Note: This command is not supported for a Vserver with Infinite Volume.

Parameters
-vserver <Vserver Name> - Vserver Name
  Specifies the Vserver that contains the LUN where you import data to from the foreign disk data.
-foreign-disk <text> - Foreign Disk Serial Number
  Specifies the serial number of the Foreign Disk.
-path <path> - LUN Path
  Specifies the path of the LUN where you want to import the data of the foreign disk to. Examples of correct LUN paths are /vol/vol1/lun1 and /vol/vol1/qtree1/lun1.

Examples

cluster1::> lun import create -vserver vs1 -path /vol/vol1/lun1 -foreign-disk 6000B5D0006A0000006A020E00040000

  storage disk set-foreign-lun on page 759

lun import delete

Deletes the import relationship of the specified LUN or the specified foreign disk

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
This command deletes the import relationship of a specified LUN or a specified foreign disk.

You cannot use this command if an import is in-progress between the foreign disk and the LUN unless you use the force option. The import has to either successfully completed or be stopped before deleting the import relationship.

You can use the lun import stop command to stop the data import, and then you delete the import relationship.

Note: This command is not supported for a Vserver with Infinite Volume.

Parameters

{ -vserver <Vserver Name> - Vserver Name
  Specifies the Vserver that contains the LUN that you want to delete the import relationship.

-path <path> - LUN Path
  Specifies the path of the LUN where you want to delete the import relationship. Examples of correct LUN paths are /vol/vol1/lun1 and /vol/vol1/qtree1/lun1.

| -foreign-disk <text> | - Foreign Disk Serial Number
  Specifies the serial number of the foreign disk.

[-force {true|false}] - Force Delete
  When set to true, stops the in progress data import.

Examples

cluster1::> lun import delete -vserver vs1 -path /vol/vol2/lun2
Deletes the import relationship of lun2 at the path /vol/vol2/lun2.

```
cluster1::> lun import delete -vserver vs0 -foreign-disk 6000B5D0006A0000006A20E00040000
```

### lun import pause

Pause the import for the specified LUN

**Availability:** This command is available to cluster administrators at the advanced privilege level.

**Description**
This command pauses the data import to a specified LUN.

This command does not reset all import checkpoints. To resume a paused import, use the lun import resume command to retart from the last checkpoint taken before you paused the data import.

If you want to resume the data import from the beginning, use the lun import stop command. Then use the lun import start command.

**Note:** This command is not supported for a Vserver with Infinite Volume.

**Parameters**

- `-vserver <Vserver Name>` - Vserver Name
  
  Specifies the Vserver that contains the LUN you want to pause the data import to.

- `-path <path>` - LUN Path
  
  Specifies the path of the LUN you want to pause the data import to. Examples of correct LUN paths are /vol/vol1/lun1 and /vol/vol1/qtree1/lun1.

**Examples**

```
cluster1::> lun import pause -vserver vs1 -path /vol/vol2/lun2
```

### lun import prepare-to-downgrade

Prepares LUN import to be downgraded

**Availability:** This command is available to cluster administrators at the advanced privilege level.

**Description**

This command prepares the cluster for a downgrade to a version of Data ONTAP earlier than 8.3.1 by disabling the online LUN import feature. Before using this command verify that all LUNs in an import relationships are offline by running `lun show`.

**Examples**

```
cluster1::> lun import prepare-to-downgrade
```

**Related references**

- [lun show](#) on page 164
lun import resume
Resume the import for the specified LUN

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
Resumes the data import to a specified LUN.

The import starts from the last checkpoint taken before you paused the data import.

If you want to resume the data import from the beginning, use the lun import stop command. Then use the lun import start command.

Note: This command is not supported for a Vserver with Infinite Volume.

Parameters
- `vserver <Vserver Name> - Vserver Name
  Specifies the Vserver that contains the LUN you want to resume the data import to.
- `path <path> - LUN Path
  Specifies the path of the LUN that you want to resume the data import to. Examples of correct LUN paths are /vol/vol1/lun1 and /vol/vol1/qtree1/lun1.

Examples

cluster1::> lun import resume -vserver vs1 -path /vol/vol2/lun2

lun import show
Display a list of import relationships

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
This command displays information about the import relationships.

Note: This command is not supported for a Vserver with Infinite Volume.

Parameters

{-fields <fieldname>, ...}
  If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-'-fields ?' to display the fields to specify.

{-instance}
  If you specify the -instance parameter, the command displays detailed information about all fields.

[vserver <Vserver Name>] - Vserver Name
  Displays import relationships for a specified Vserver.

[-foreign-disk <text>] - Foreign Disk Serial Number
  Enables you to see the import relationship for a particular foreign disk with the specified serial number.

[-path <path>] - LUN Path
  Enables you to see the import relationship for a particular LUN path. Examples of correct LUN paths are /vol/vol1/lun1 and /vol/vol1/qtree1/lun1.
[-import-home-node {<nodename>|local}] - Import Home Node
   Enables you to see the node that initially started the data import and where the I/O for the foreign disk is
directed. If failover occurs, any in-progress data import restarts on the partner node.

[-import-current-node {<nodename>|local}] - Import Current Node
   Displays the node that is currently importing data and where the I/O for the foreign disk is directed. During
giveback and if the import home node is different from the current home node, import restarts on the initial
node (import-home-node).

[-operation-in-progress {import|verify}] - Operation in Progress
   Enables you to see the imports in progress or import verification in progress.

[-admin-state {stopped|started|paused}] - Admin State
   Enables you to see the import relationships for a specified administrative state. For example, you can list all
the imports that have started in a cluster.

[-operational-state {in_progress|failed|completed|stopped|paused}] - Operational State
   Enables you to see the import relationships for a specified operational state. For example, you can list all the
imports that have completed in a cluster.

[-percent-complete <integer>] - Percent Complete
   Enables you to see the percentage of completion for both import and verification. If you want to see all the
complete imports and verifications, you would specify 100.

[-imported-blocks <integer>] - Blocks Imported
   Enables you to see the number of blocks that have been imported to the LUN.

[-compared-blocks <integer>] - Blocks Compared
   Enables you to see the number of LUN and foreign disk blocks that have been compared.

[-total-blocks <integer>] - Total Blocks
   Enables you to see the total number of blocks that must be imported to complete the data import to a LUN or
the number of blocks that must be compared to complete the import verification.

[-estimated-remaining-duration {<seconds>| [<d> days] <hh>:<mm>:<ss>]}] - Estimated Remaining
   Duration
   If this parameter is specified, the command displays import or verify operations that match the specified time.

[-failure-reason <text>] - Failure Reason
   Selects LUN import operations that match this parameter value.

[-max-throughput-limit {<integer>[KB|MB|GB|TB|PB]}] - Maximum Throughput Limit (per sec)
   Selects the LUN import operations that match this parameter value. This value is the throughput limit at which
an import or verify will be throttled. By default, there is no throttling.

[-current-throughput {<integer>[KB|MB|GB|TB|PB]}] - Current Throughput (per sec)
   Selects the LUN import operations that match this parameter value. This value is the current throughput for an
in-progress import or verify operation.

[-qos-policy-group <text>] - QoS Policy Group
   Selects the LUN import operations that match this parameter value. This value is the QoS policy group
associated with an import relationship.

**lun import start**

Start the import for the specified LUN

**Availability:** This command is available to cluster administrators at the advanced privilege level.

**Description**

This command initiates the data import to a specified LUN.

You must use the lun import create command to create an import relationship between a LUN and a foreign disk before you can initiate the data import.

**Note:** This command is not supported for a Vserver with Infinite Volume.

**Parameters**

- **-vserver <Vserver Name>** - Vserver Name
  Specifies the Vserver that contains the LUN you want to import data to.

- **-path <path>** - LUN Path
  Specifies the path of the LUN that you want to import data to. Examples of correct LUN paths are /vol/vol1/lun1 and /vol/vol1/qtree1/lun1.

**Examples**

```
cluster1::> lun import start -vserver vs1 -path /vol/vol2/lun2
```

**lun import stop**

Stop the import for the specified LUN

**Availability:** This command is available to cluster administrators at the advanced privilege level.

**Description**

This command stops the data import into a specified LUN.

After you stop the data import and if you start the import again using lun import start command, then the import restarts from the beginning.

**Note:** This command is not supported for a Vserver with Infinite Volume.
Parameters

-vserver <Vserver Name> - Vserver Name
   Specifies the Vserver that contains the LUN you want to stop importing data to.

-path <path> - LUN Path
   Specifies the path of the LUN that you want to stop the data import to.

Examples

   cluster1::> lun import stop -vserver vs1 -path /vol/vol2/lun2

Related references

   lun import start on page 190

lun import throttle

Modify the max throughput limit for the specified import relationship

Availability: This command is available to cluster administrators at the advanced privilege level.

Description

This command throttles the speed of the import for a given LUN by specifying a maximum throughput limit on the import.

Parameters

-vserver <Vserver Name> - Vserver Name
   Specifies the Vserver that contains the LUN to which data from the foreign disk is imported.

-path <path> - LUN Path
   Specifies the path of the LUN to which data from the foreign disk is imported. Examples of correct LUN paths are /vol/vol1/lun1 and /vol/vol1/qtree1/lun1.

-max-throughput-limit {<integer>[KB|MB|GB|TB|PB]} - Maximum Throughput Limit (per sec)
   Specifies the maximum amount of throughput to be allocated for processing import requests on the bound LUN. At the time of creation, the default is zero. A value of zero implies that import traffic is processed by the system at best effort rate along with on-going user I/O. A non-zero value indicates that import will be throttled at a rate which is at most the maximum throughput limit set.

Examples

   cluster1::*> lun import throttle -vserver vs1 -path /vol/vol1/lun1 -max-throughput-limit 3M

lun import verify commands

Manage Foreign LUN import verify

   Note: These commands are not supported for a Vserver with Infinite Volume.

lun import verify start

Start the verification of the foreign disk and LUN data

Availability: This command is available to cluster administrators at the advanced privilege level.
Description
This command compares the LUN and the foreign disk block by block. You are not required to run this command; it is optional. Before you can do this verification process, the operation state must be stopped or completed. Use the lun import show command to determine the operation state.

If a block mismatch occurs, the verification process stops.

Verification must be done offline. Ensure the foreign disk and LUN cannot be accessed by a host. To prevent access of the LUN, the LUN should be taken offline administratively using the lun offline command.

Note: The specified LUN must be in an import relationship with a foreign disk before you can verify the data import.

Note: This command is not supported for a Vserver with Infinite Volume.

Parameters
-vserver <Vserver Name> - Vserver Name
  Specifies the Vserver that contains the LUN you want to compare block by block with the foreign disk.

-path <path> - LUN Path
  Specifies the path of the LUN that you want to compare the foreign disk to. Examples of correct LUN paths are /vol/vol1/lun1 and /vol/vol1/qtree1/lun1.

Examples

```
cluster1::> lun import verify start -vserver vs1 -path /vol/vol2/lun2
```

lun import verify stop

Stop the verify for the specified LUN

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
This command stops the block by block verification of the foreign disk and LUN data.

Note: This command is not supported for a Vserver with Infinite Volume.

Parameters
-vserver <Vserver Name> - Vserver Name
  Specifies the Vserver that contains the LUN you want to stop block by block comparison with the foreign disk.

-path <path> - LUN Path
  Specifies the path of the LUN that you want to stop the block by block comparison. Examples of correct LUN paths are /vol/vol1/lun1 and /vol/vol1/qtree1/lun1.

Examples

```
cluster1::> lun import verify stop -vserver vs1 -path /vol/vol2/lun2
```

Related references

`lun import verify start` on page 191
lun mapping commands

Manage LUN Maps

lun mapping add-reporting-nodes

Add Reporting Nodes

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
This command is used before or after a data mobility event that modifies the owning node of the LUN to add the new optimized nodes to the specified LUN mapping's reporting nodes.

For more information on managing reporting nodes in response to data mobility events, please see the Data ONTAP SAN Administration Guide.

Note: This command is not supported for a Vserver with Infinite Volume.

Parameters
-vserver <Vserver Name> - Vserver Name

Specifies the name of the Vserver containing the LUN.

{-path <path> - LUN Path

Specifies the path of the LUN. Examples of correct LUN paths are /vol/vol1/lun1 and /vol/vol1/qtree1/lun1.

|-volume <volume name> - Volume Name

Specifies the volume that contains the LUN.

[-qtree <qtree name>] - Qtree Name

Specifies the qtree that contains the LUN.

-lun <text> - LUN Name

Specifies the LUN name.

-igroup | -g <text> - Igroup Name

Specifies the igroup the LUN is mapped to.

{ -local-nodes [true] - Add Nodes for Current LUN Location

Add the current LUN owner node and HA partner to the LUN mapping's reporting nodes.

This option should be used after a LUN mobility event to restore optimized access to the LUN.

|-destination-aggregate <aggregate name> - Add Nodes for Aggregate

Add the specified aggregate's owner node and HA partner to the LUN mapping's reporting nodes.

This option may be used prior to a LUN mobility event that changes the LUN's containing aggregate.

|-destination-volume <volume name> - Add Nodes for Volume

Add the specified volume's owner node and HA partner to the LUN mapping's reporting nodes.

This option may be used prior to a LUN mobility event that changes the LUN's containing volume.

|-all [true] - Add All Nodes (privilege: advanced)

Set the LUN mapping to report on all nodes in preparation for a revert to a previous version of Data ONTAP.
lun mapping create

Map a LUN to an initiator group

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
This command maps a LUN to all of the initiators in an initiator group (igroup). After you map the LUN, the LUN is visible to all initiators in the igroup.

Data ONTAP ensures that there are no LUN map conflicts whether the LUN is offline or online. A LUN map conflict is a mapping that would violate either of the following rules:

- Each LUN can be mapped to an initiator only once. A LUN can be mapped to multiple igroups as long as each igroup has a distinct set of initiators.
- LUN IDs must be unique such that every initiator has a unique ID for each LUN to which it is mapped. If you map a LUN to an igroup, the LUN ID for that mapping cannot be reused by any of the initiators in that igroup.

In order to determine if a LUN ID is valid for a mapping, Data ONTAP checks each initiator in the igroup to make sure that the LUN ID is not used for another mapping that includes that initiator.

Note: Prior to mapping a LUN, you must have at least one iSCSI or FCP LIF provisioned on the LUN’s owner node and high-availability partner node.

Note: This command is not supported for a Vserver with Infinite Volume.

Parameters
-vserver <Vserver Name> - Vserver Name
  Specifies the Vserver that contains the LUN you want to map.

{-path <path> - LUN Path
  Specifies the path of the LUN that you want to map. Examples of correct LUN paths are /vol/vol1/lun1 and /vol/vol1/qtree1/lun1.

| -volume <volume name> - Volume Name
  Specifies the volume that contains the LUN you want to map.

[-qtree <qtree name>] - Qtree Name
  Specifies the qtree that contains the LUN you want to map.

-lun <text> - LUN Name
  Specifies the LUN name that you want to map.

-igroup | -g <text> - Igroup Name
  Specifies the igroup that you want to map.
[-lun-id <integer>] - LUN ID
Specifies the LUN ID for the mapping. The LUN ID is specific to the mapping, not to the LUN itself. This is used by the initiators in the igroup as the Logical Unit Number for the initiator when accessing the storage.

[-additional-reporting-node <nodename>] - Additional Reporting Node (privilege: advanced)
Specifies an additional node to populate the -reporting-nodes list when creating the LUN mapping. The specified node's high availability partner will be automatically populated as well. Use this parameter when preferred data mobility destinations are known ahead of time and the appropriate paths can be pre-configured.

Examples
```bash
cluster1::> lun mapping create -vserver vs1 -path /vol/vol1/lun1 -igroup ig1 -lun-id 8
```

**lun mapping delete**
Unmap a LUN from an initiator group

**Availability:** This command is available to cluster and Vserver administrators at the admin privilege level.

**Description**
This command unmaps a LUN from an initiator group. After you use this command, the LUN is not visible to any of the initiators in the initiator group.

**Note:** This command is not supported for a Vserver with Infinite Volume.

**Parameters**
- **-vserver <Vserver Name>** - Vserver Name
  Selects the LUN maps for the Vserver that matches the parameter value.

  { **-path <path>** - LUN Path
  Specifies the path of the LUN you want to unmap. Examples of correct LUN paths are /vol/vol1/lun1 and /vol/vol1/qtree1/lun1.

  } **-volume <volume name>** - Volume Name
  Specifies the volume of the LUN you want to unmap.

  **-qtree <qtree name>** - Qtree Name
  Specifies the qtree of the LUN you want to unmap.

  **-lun <text>** - LUN Name
  Specifies the name of the LUN you want to unmap.

  **-igroup | -g <text>** - Igroup Name
  Specifies the initiator group that you want to unmap the LUN from.

Examples
```bash
cluster1::> lun mapping delete -vserver vs1 -path /vol/vol1/lun1 -igroup ig1
```

**lun mapping remove-reporting-nodes**
Remove Reporting Nodes

**Availability:** This command is available to cluster and Vserver administrators at the admin privilege level.
**Description**
This command is used after a data mobility event to remove reporting nodes that are no longer required for optimized access from the specified LUN mapping.

For more information on managing reporting nodes in response to data mobility events, please see the Data ONTAP SAN Administration Guide.

**Note:** This command is not supported for a Vserver with Infinite Volume.

**Parameters**

- `-vserver <Vserver Name>` - Vserver Name
  Specifies the name of the Vserver containing the LUN.

- `-path <path>` - LUN Path
  Specifies the path of the LUN. Examples of correct LUN paths are `/vol/vol1/lun1` and `/vol/vol1/qtree1/lun1`.

- `-volume <volume name>` - Volume Name
  Specifies the volume that contains the LUN.

- `-qtree <qtree name>` - Qtree Name
  Specifies the qtree that contains the LUN.

- `-lun <text>` - LUN Name
  Specifies the LUN name.

- `-igroup | -g <text>` - Igroup Name
  Specifies the igroup the LUN is mapped to.

- `-remote-nodes [true]` - Remove Remote Nodes for LUN Location
  If specified, remove all nodes other than the LUN's owner and HA partner from the LUN mapping's reporting nodes.

**Examples**

```bash
cluster1::> lun mapping remove-reporting-nodes -vserver vs1 -path /vol/vol1/lun1 -igroup ig1
```

**lun mapping show**

Lists the mappings between LUNs and initiator groups.

**Availability:** This command is available to cluster and Vserver administrators at the admin privilege level.

**Description**
This command lists the mappings between LUNs and initiator groups.

**Parameters**

- `[-fields <fieldname>, ...]`
  If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

- `[-instance]]`
  If you specify the `-instance` parameter, the command displays detailed information about all fields.
[-vserver <Vserver Name>] - Vserver Name
Selects the LUN maps for the Vserver that matches the parameter value.

{ [-path <path>] - LUN Path
Selects the LUN maps for the LUN with the path that matches the parameter value. Examples of correct LUN paths are /vol/vol1/lun1 and /vol/vol1/qtree1/lun1.

[-volume <volume name>] - Volume Name
Selects the LUN maps for the volumes that match the parameter value.

[-qtree <qtree name>] - Qtree Name
Selects the LUN maps for the queue trees that match the parameter value.

[-lun <text>] - LUN Name
Selects the LUN maps for the LUNs with a name that matches the parameter value.

[-igroup | -g <text>] - Igroup Name
Selects the LUN maps for the igroup that matches the parameter value.

[-ostype {solaris|windows|hpux|aix|linux|netware|vmware|openvms|xen|hyper_v}] - Igroup OS Type
Selects the LUN maps for the initiator groups with the OS type that matches the parameter value. The possible OS types are:
* solaris - the LUN stores Solaris raw disk in a single-slice partition.
* windows - the LUN stores a raw disk type in a single-partition Windows disk using the Master Boot Record (MBR) partitioning style.
* hpux - the LUN stores HP-UX data.
* linux - the LUN stores a Linux raw disk without a partition table.
* netware - the LUN stores NetWare data.
* vmware - the LUN stores VMWare data.
* openvms - the LUN stores Open-VMS data.
* xen - the LUN stores Xen data.
* hyper_v - the LUN stores Windows Server 2008 or Windows Server 2012 Hyper-V data.

[-protocol <protocol_enum>] - Igroup Protocol Type
Selects the LUN maps for initiator groups with a protocol that matches the parameter value. Possible values include FCP, iSCSI, or mixed.

[-lun-id <integer>] - LUN ID
Selects the LUN maps with a LUN ID that matches the parameter value.

[-portset <text>] - Portset Binding Igroup
Selects the LUN maps for initiator groups bound to the portset that matches the parameter value.

[-alua {true|false}] - ALUA
Selects the LUN maps with ALUA settings that match the parameter value.

[-initiators | -n <text>, ...] - Initiators
Selects the LUN maps for initiator groups containing the initiators that match the parameter value.

[-node <nodename>] - LUN Node
Selects the LUN maps for nodes that match the parameter value.
[-reporting-nodes <nodename>, ...] - Reporting Nodes

Selects the LUN maps that match the parameter value.

### Manage Lun Move Operations

Manage LUN move operations

**Note:** These commands are not supported for a Vserver with Infinite Volume.

#### lun move cancel

Cancel a LUN move operation before the new LUN has been created.

**Availability:** This command is available to cluster and Vserver administrators at the advanced privilege level.

**Description**

The `lun move cancel` command cancels an ongoing LUN move operation prior to creation of the new LUN. The command fails if the LUN already exists at the destination path; in that case, allow the current move operation to complete and then move it back using the `lun move start` command.

All data transfers will be halted. If the source LUN was quiesced, it will be restored to normal operation.

**Note:** This is an advanced command because the preferred way to cancel a LUN move operation is to wait until the new LUN becomes visible, and then move it back.

**Note:** This command is not supported for a Vserver with Infinite Volume.

#### Parameters

- `-vserver <Vserver Name>` - Vserver Name
  
  Specifies the name of the Vserver that will host the destination LUN.

- `-destination-path <path>` - Destination Path
  
  Specifies the full path to the new LUN, in the format /vol/<volume>[/<qtree>]/<lun>.

#### Examples

```
cluster1::*> lun move cancel -vserver vs1 -destination-path /vol/vol2/lun2
```

#### Related references

`lun move start` on page 202
lun move modify
Modify an ongoing LUN move operation

**Availability:** This command is available to cluster and Vserver administrators at the admin privilege level.

**Description**
The `lun move modify` command modifies the maximum throughput of an ongoing move operation.

**Note:** This command is not supported for a Vserver with Infinite Volume.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-vserver &lt;Vserver Name&gt;</code></td>
<td>Vserver Name Specifies the name of the Vserver that will host the destination LUN.</td>
</tr>
<tr>
<td><code>-destination-path &lt;path&gt;</code></td>
<td>Destination Path Specifies the full path to the new LUN, in the format /vol/&lt;volume&gt;[/&lt;qtree&gt;/]&lt;lun&gt;.</td>
</tr>
<tr>
<td>`-max-throughput {&lt;integer&gt; [KB</td>
<td>MB</td>
</tr>
</tbody>
</table>

**Examples**
```
cluster1::> lun move modify -vserver vs1 -destination-path /vol/vol2/lun2 -max-throughput 25MB
```

lun move pause
Pause an ongoing LUN move operation

**Availability:** This command is available to cluster and Vserver administrators at the admin privilege level.

**Description**
The `lun move pause` command pauses an ongoing move operation. Use the `lun move resume` command to resume the move operation.

**Note:** This command is not supported for a Vserver with Infinite Volume.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-vserver &lt;Vserver Name&gt;</code></td>
<td>Vserver Name Specifies the name of the Vserver that will host the destination LUN.</td>
</tr>
<tr>
<td><code>-destination-path &lt;path&gt;</code></td>
<td>Destination Path Specifies the full path to the new LUN, in the format /vol/&lt;volume&gt;[/&lt;qtree&gt;/]&lt;lun&gt;.</td>
</tr>
</tbody>
</table>

**Examples**
```
cluster1::> lun move pause -vserver vs1 -destination-path /vol/vol2/lun2
```
lun move resume
Resume a paused LUN move operation

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The lun move resume command resumes a paused move operation.

Note: This command is not supported for a Vserver with Infinite Volume.

Parameters
{-vserver <Vserver Name> - Vserver Name
   Specifies the name of the Vserver that will host the destination LUN.

-destination-path <path> - Destination Path
   Specifies the full path to the new LUN, in the format /vol/<volume>/[<qtree>]/<lun>.

Examples
cluster1::> lun move resume -vserver vs1 -destination-path /vol/vol2/lun2

Related references
lun move pause on page 199

lun move show
Display a list LUNs currently being moved

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The lun move show command shows information about LUNs currently being moved in the cluster.

Note: This command is not supported for a Vserver with Infinite Volume.

Parameters
[-fields <fieldname>, ...]
   If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

[-instance ]
   If you specify the -instance parameter, the command displays detailed information about all fields.

[-vserver <Vserver Name>] - Vserver Name
   Selects LUN move operations that match this parameter value.

[-destination-path <path>] - Destination Path
   Selects LUN move operations that match this parameter value.

[-source-path <path>] - Source Path
   Selects LUN move operations that match this parameter value.
[{-is-promoted-late (true|false)}] - Is Destination Promoted Late
Selects LUN move operations that match this parameter value.

[{-max-throughput (<integer> [KB|MB|GB|TB|PB])}] - Maximum Transfer Rate (per sec)
Selects LUN move operations that match this parameter value.

[{-job-status (Preparing|Allocation-Map|Data|Destroying|Paused-Admin|Paused-Error|Complete|Destroyed)}] - LUN Move Status
Selects LUN move operations that match this parameter value. The possible values are:
- **Preparing** - the LUN move job is in Preparing status.
- **Allocation-Map** - the LUN move job is in Allocating status.
- **Data** - the LUN move job is in Moving Data status.
- **Destroying** - the LUN move job is in Destroying status.
- **Paused-Admin** - the LUN move job is in Paused By Admin status.
- **Paused-Error** - the LUN move job is in Paused By Error status.
- **Complete** - the LUN move job is in Complete status.
- **Destroyed** - the LUN move job is in Destroyed status.

[{-progress-percent <percent}>] - LUN Move Progress (%)
Selects LUN move operations that match this parameter value.

[{-elapsed-time <time_interval}>] - Elapsed Time
Selects LUN move operations that match this parameter value.

[{-cutover-time <time_interval}>] - Cutover Time
Selects LUN move operations that match this parameter value.

[{-is-snapshot-fenced (true|false)}] - Is Snapshot Fenced
Selects LUN move operations that match this parameter value.

[{-is-destination-ready (true|false)}] - Is Destination Ready
Selects LUN move operations that match this parameter value.

[{-last-failure-reason <text}>] - Last Failure Reason
Selects LUN move operations that match this parameter value.

### Examples

```
cluster1::> lun move show
Vserver   Destination Path                Status          Progress
--------- ------------------------------- --------------- --------
vs1       /vol/vol2/lun1                  Data            35%
vs1       /vol/vol2/lun2                  Complete        100%
2 entries were displayed.
```

The example above displays information about all the LUN move operations in the cluster.

```
cluster1::> lun move show -vserver vs1 -destination-path /vol/vol2/lun1 -instance

Destination Vserver Name: vs1
Destination Path: /vol/vol2/lun1
Source Path: /vol/vol1/lun1
Is Destination Promoted Early: false
Maximum Transfer Rate (per sec): 0B
LUN Move Status: Data
```
lun move start

Start moving a LUN from one volume to another within a Vserver

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The lun move start command initiates moving of a LUN from one volume to another. The destination volume can be located on the same node as the original volume or on a different node.

Note: Use lun move-in-volume command if you want to rename the LUN or move it within the same volume.

Note: This command does not support movement of LUNs that are created from files.

Note: This command is not supported for a Vserver with Infinite Volume.

Parameters
-vserver <Vserver Name> - Vserver Name
Specifies the name of the Vserver that will host the new LUN.

| -destination-path <path> - Destination Path
| Specifies the full path to the new LUN, in the format /vol/<volume>[/<qtree>]/<lun>.

-source-path <path> - Source Path
Specifies the full path to the source LUN, in the format /vol/<volume>[/<qtree>]/<lun>.

[| -promote-late [true]] - Promote Late
| Optionally specifies that the destination LUN needs to be promoted late.
| If the destination is promoted early, the new LUN will be visible immediately. However, Snapshot copies of the volume containing the new LUN cannot be taken until the LUN move operation reaches 'Moving Data' status.
| If the destination is promoted late, the new LUN will be visible only after it has been fully framed. However, the LUN move job will not block the creation of Snapshot copies of the volume containing the new LUN.
| If this parameter is not specified, the destination LUN will be promoted early.

[-max-throughput (<integer>[KB|MB|GB|TB|PB])] - Maximum Transfer Rate (per sec)
Optionally specifies the maximum amount of data, in bytes, that can be transferred per second in support of this operation. This mechanism can be used to throttle a transfer, to reduce its impact on the performance of the source and destination nodes.

If this parameter is not specified, throttling is not applied to the data transfer.

Note: The specified value will be rounded up to the nearest megabyte.

Examples
cluster1:/> lun move start -vserver vs1 -destination-path /vol/vol2/lun2 -source-path /vol/vol1/lun1
lun persistent-reservation commands

Manage SCSI-2 and SCSI-3 persistent reservations

Commands used for managing persistent reservations on LUNs.

lun persistent-reservation clear

Clear the SCSI-3 persistent reservation information for a given LUN

Availability: This command is available to cluster and Vserver administrators at the advanced privilege level.

Description

Clears the persistent reservation for the specified LUN.

Note: This command is not supported for a Vserver with Infinite Volume.

Parameters

-vserver <Vserver Name> - Vserver Name
  Specifies the Vserver.

{ -path <path> - LUN Path
  Specifies the path of the LUN. Examples of correct LUN paths are /vol/vol1/lun1 and /vol/vol1/qtree1/lun1.
}

| -volume <volume name> - Volume Name
  Specifies the volume.

-lun <text> - LUN Name
  Specifies the name of the LUN.

[{-qtree <qtree name>}] - Qtree Name
  Specifies the qtree.

Examples

cluster1::*> lun persistent-reservation clear -vserver vs_1 -path /vol/vol_1/lun_1

lun persistent-reservation show

Display the current reservation information for a given LUN

Availability: This command is available to cluster and Vserver administrators at the advanced privilege level.

Description

Displays reservation information for a specified LUN in a Vserver. Unlike other show commands, the user must specify the LUN.
Parameters

\{ [-fields \<fieldname\>, ...] \}

If you specify the `-fields \<fieldname\>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

\{ [-instance] \}

If you specify the `-instance` parameter, the command displays detailed information about all fields.

- **-vserver <Vserver Name>** - Vserver Name
  
  Specifies the Vserver.

{ -path <path> } - LUN Path

  Specifies the path of the LUN. Examples of correct LUN paths are `/vol/vol1/lun1` and `/vol/vol1/qtree1/lun1`.

- **-volume <volume name>** - Volume Name
  
  Specifies the volume.

- **-lun <text>** - LUN Name
  
  Specifies the name of the LUN.

[ -qtree <qtree name> ] - Qtree Name

  Specifies the qtree.

[ -scsi-revision {scsi2|scsi3} ] - SCSI Revision

  Selects the reservations that match this parameter value.

[ -entry-type {reservation|registration} ] - Reservation or Registration

  Selects the reservations that match this parameter value.

[ -protocol {fcp|iscsi} ] - Protocol

  Selects the reservations that match this parameter value.

[ -reservation-key <text> ] - Reservation Key

  Selects the reservations that match this parameter value.

[ -reservation-type-code <text> ] - Reservation Type

  Selects the reservations that match this parameter value. The possible values for SCSI-3 reservations are:

  - write exclusive
  - exclusive access
  - write exclusive registrants only
  - exclusive access registrants only
  - write exclusive all registrants
  - exclusive access all registrants

  and for SCSI-2 are:

  - regular
  - third party

[ -initiator-name <text> ] - Initiator Name

  Selects the reservations that match this parameter value.
[-aptpl {true|false}] - Persist Through Power Loss

Selects the reservations that match this parameter value. If true, the reservation will be preserved over a power loss. If false, it will not. This value is for SCSI-3 reservations only.

[-target-wwpn <text>] - FCP Target WWPN

Selects the reservations that match the specified World Wide Port Name (WWPN).

[-isid <text>] - Initiator Session ID

Selects the reservations that match this parameter value.

[-tpgroup-tag <integer>] - TPGroup Tag

Selects the reservations that match the specified target portal group tag. The tag identifies the tpgroup the reservation was made over.

[-third-party-initiator-name <text>] - Third Party Initiator Name

Selects the reservations that match this parameter value (the initiator name that the reservation was made for). This is specific to third party reservation types, which is indicated by reservation-type-code.

Examples

```
cluster1::*> lun persistent-reservation show -vserver vs_1 /vol/vol_1/lun_1

```

lun portset commands

Manage portsets

**lun portset add**

Add iSCSI/FCP LIFs to a portset

**Availability:** This command is available to cluster and Vserver administrators at the admin privilege level.

**Description**

This command adds existing iSCSI and FCP LIFs to a port set. To create a new port set, use the *lun portset create* command.

Use the *network interface create* command to create new LIFs.

**Note:** This command is not supported for a Vserver with Infinite Volume.

**Parameters**

- `-vserver <Vserver Name>` - Vserver Name
  
  Specifies the Vserver.

- `-portset <text>` - Portset Name
  
  Specifies the port set you want to add the LIFs to.

- `-port-name <port_name>, ...` - LIF or TPG Name
  
  Specifies the LIF name you want to add to the port set.
**Examples**

```
cluster1::> portset add -vserver vs1 -portset ps1 -port-name lif1
```

**Related references**

- `lun portset create` on page 206
- `network interface create` on page 281

**lun portset create**

Creates a new portset

**Availability:** This command is available to cluster and Vserver administrators at the `admin` privilege level.

**Description**

This command creates a new port set for FCP and iSCSI. The port set name can include a maximum of 96 characters. You can add LIFs to the new port set. If you do not add a LIF to the port set, you create an empty port set. To add LIFs to an existing port set, use the `lun portset add` command.

After you create a port set, you must bind the port set to an igroup so the host knows which FC or iSCSI LIFs to access. If you do not bind an igroup to a port set, and you map a LUN to an igroup, then the initiators in the igroup can access the LUN on any LIF on the Vserver.

**Note:** You cannot bind an igroup to an empty port set because the initiators in the igroup would have no LIFs to access the LUN.

**Note:** This command is not supported for a Vserver with Infinite Volume.

**Parameters**

- `-vserver <Vserver Name>` - Vserver Name
  
  Specifies the Vserver.

- `-portset <text>` - Portset Name
  
  Specifies the name of the new port set. A port set name is a case-sensitive name that must contain one to 96 characters. Spaces are not allowed.

- `[ -port-name <port_name>, ... ]` - LIF Or TPG Name
  
  Specifies the name of the logical interface that you want to add to the portset you want to create.

- `{ [ -protocol <protocol_enum> ] }` - Protocol
  
  Specifies if the portset protocol type is `fcp`, `iscsi`, or `mixed`. The default is `mixed`.

  - `-fcp | -f [true]` - FCP
    
    Specifies FCP as the protocol type of the new port set.

  - `-iscsi | -i [true]` - iSCSI
    
    Specifies iSCSI as the protocol type of the new port set.

**Examples**

```
cluster1::> portset create -vserver vs1 -portset ps1 -protocol mixed
```

Creates a port set `ps1` on Vserver `vs1` with the protocol type of `mixed`. 
cluster1::> portset create -vserver vs1 -portset iscsips -protocol iscsi

Creates a port set iscsips on Vserver vs1 with the protocol type of iscsi.

cluster1::> portset create -vserver vs1 -portset fcppc -protocol fcp

Creates a port set fcppc on Vserver vs1 with the protocol type of fcp.

cluster1::> portset create -vserver vs1 -portset ps2 -protocol mixed -port-name l1l

Related references
lun portset add on page 205

lun portset delete

Delete the portset

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
This command deletes an existing port set. By default, you cannot delete a port set if it is bound to an initiator group. If a port set is bound to an initiator group, you can do one of the following:

• specify the force option to unbind the port set from the initiator group and delete the port set.
• use the lun igroup unbind command to unbind the port set from the initiator group. Then you can delete the port set.

Note: This command is not supported for a Vserver with Infinite Volume.

Parameters
-vserver <Vserver Name> - Vserver Name
  Specifies the Vserver.

-portset <text> - Portset Name
  Specifies the port set you want to delete.

[-force | -f [true]] - Force
  Forcibly unbinds the port set from the initiator group.

Examples
cluster1::> portset delete -vserver vs1 -portset ps1

Related references
lun igroup unbind on page 184

lun portset remove

Remove iSCSI/FCP LIFs from a portset

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.
Description
This command removes a LIF from a port set.

You cannot remove the last LIF in a port set if the port set is bound to an initiator group (igroup). To remove the last LIF in a port set, use the `lun igroup unbind` command to unbind the port set from the igroup. Then you can remove the last LIF in the port set.

Note: This command is not supported for a Vserver with Infinite Volume.

Parameters
- `vserver <Vserver Name>` - Vserver Name
  Specifies the Vserver.
- `portset <text>` - Portset Name
  Specifies the port set you want to remove a LIF from.
- `port-name <port_name>, ...` - LIF or TPG Name
  Specifies the LIF name you want to remove from the port set.

Examples
```
cluster1::> port set remove -vserver vs1 -portset ps1 -port-name lif1
```

Related references
`lun igroup unbind` on page 184

`lun portset show`
Displays a list of portsets

Availability: This command is available to `cluster` and Vserver administrators at the `admin` privilege level.

Description
This command displays the LIFs in a port set. By default, the command displays all LIFs in all port sets.

Parameters

```
{| [-fields <fieldname>, ...]
  If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

| [-instance]]
  If you specify the `-instance` parameter, the command displays detailed information about all fields.

[-vserver <Vserver Name>] - Vserver Name
  Selects the port sets that match this parameter value.

[-portset <text>] - Portset Name
  Selects the port sets that match this parameter value.

[-port-name <port_name>, ...] - LIF or TPG Name
  Selects the port sets that match this parameter value.

[-protocol <protocol_enum>] - Protocol
  Selects the port sets that match this parameter value.
```
[-port-count <integer>] - Number Of Ports

Selects the port sets that match this parameter value.

[-igroups <igroup>, ...] - Bound To Igroups

Selects the port sets that match this parameter value.

### Examples

```
cluster1::> lun portset show
Vserver  Portset  Protocol  Port Names               Igroups
--------- ------------ -------- ----------------------- ------------
vs1       ps0     mixed    lif1, lif2               igroup1
ps1       iscsi   lif3                      igroup2
ps2       fcp     lif4                      -
3 entries were displayed.
```

The example above displays all port sets.

```
cluster1::> lun portset show -port-count 0
Vserver  Portset  Protocol  Port Names               Igroups
--------- ------------ -------- ----------------------- ------------
vs1       p1     iscsi -                       -
```

The example above displays the port sets that contain zero LIFs.

```
cluster1::> lun portset show -protocol iscsi
Vserver  Portset  Protocol  Port Names               Igroups
--------- ------------ -------- ----------------------- ------------
vs1       p1     iscsi -                       -
vs1       iscsips iscsi lif1               igroup1
2 entries were displayed.
```

The example above displays the port sets that have the iSCSI protocol.

```
cluster1::> lun portset show -port-name lif1
Vserver  Portset  Protocol  Port Names               Igroups
--------- ------------ -------- ----------------------- ------------
vs1       iscsips iscsi lif1               igroup1
```

The example above displays the port sets that match the port name lif1.

### lun transition commands

Manage LUN Transition from Data ONTAP 7-Mode

#### lun transition show

Display the status of LUN transition processing

**Availability:** This command is available to `cluster` administrators at the `advanced` privilege level.

**Description**

The `lun transition show` command displays information about the LUN transition processing status of volumes. If no parameters are specified, the command displays the following information about all volumes:

- Vserver name
- Volume name
- Transition status
Parameters

[-fields <fieldname>, ...]
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

[-instance]]
If you specify the -instance parameter, the command displays detailed information about all fields.

[-vserver <Vserver Name>] - Vserver Name
Selects the volumes in the specified Vserver.

[-volume <volume name>] - Volume Name
Selects the volumes with the specified name.

[-status {none|complete|failed|active}] - Transition Status
Selects the volumes that match the specified transition status. The possible status values are:

- active - The volume is in an active SnapMirror transition relationship and not yet transitioned.
- complete - LUN transition has completed for the volume.
- failed - LUN transition has failed for the volume.
- none - The volume did not contain LUNs to transition from Data ONTAP 7-Mode.

[-vserver-uuid <UUID>] - Vserver UUID
Selects the volumes in the Vserver that matches the specified UUID.

[-node <nodename>] - Filer ID
Selects the volumes that match the specified node.

Examples

The following example displays LUN transition information for all volumes in a Vserver named vs1:

```
cluster1::*> lun transition show -vserver vs1
Vserver             Volume      Transition Status
-------------------- ------------------ -----------------
vs1                  vol0        none
vol1                complete
vol2                failed
vol3                active
4 entries were displayed.
```

lun transition start

Start LUN Transition Processing

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
The lun transition start command starts LUN transition for the specified volume. Normally, transition is started automatically when snapmirror break is issued for the volume, this command allows restarting in the event automatic transitioning was interrupted or failed.

Note: This command is not supported for a Vserver with Infinite Volume.
Parameters

-vserver <Vserver Name> - Vserver Name
The name of the Vserver containing the volume. If only one data Vserver exists, you do not need to specify this parameter.

-volume <volume name> - Volume Name
The name of the volume to restart LUN transition.

Examples

The following example starts LUN transition on a volume named volume1 in a Vserver named vs1:

```
cluster1::*> lun transition start -vserver vs1 -volume volume1
```

Related references

snapmirror break on page 498

lun transition 7-mode commands

The 7-mode directory

lun transition 7-mode delete

Delete an Untransitioned 7-Mode LUN

Availability: This command is available to cluster administrators at the advanced privilege level.

Description

The lun transition 7-mode delete command deletes an untransitioned LUN copied from a Data ONTAP 7-Mode system. This allows the admin to recover space from the volume for LUNs that may not be transitioned to clustered Data ONTAP without disrupting LUNs that have transitioned, for example, if the LUN is an unsupported OS type.

Note: This command is not supported for a Vserver with Infinite Volume.

Parameters

-vserver <Vserver Name> - Vserver Name
This specifies the name of the Vserver from which the LUN is to be deleted. If only one data Vserver exists, you do not need to specify this parameter.

-path <path> - LUN Path
This specifies the path to the LUN to delete.

Examples

The following example deletes the LUN /vol/vol1/lun1 in a Vserver named vs1:

```
cluster1::*> lun transition 7-mode delete -vserver vs1 -path /vol/vol1/lun1
```
**lun transition 7-mode show**

Display the 7-Mode LUN Inventory

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

**Description**

The `lun transition 7-mode show` command displays information about LUNs copied from a Data ONTAP 7-Mode system. If no parameters are specified, the command displays the following information about all 7-Mode LUNs:

- Vserver name
- LUN path
- Operating system type
- Size
- Whether or not the LUN has been transitioned to clustered Data ONTAP

**Note:** This command is not supported for a Vserver with Infinite Volume.

**Parameters**

{ [-fields <fieldname>, ...]  
  If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.  
  }  

| [-instance ]]  
  If you specify the `-instance` parameter, the command displays detailed information about all fields.  

[-vserver <Vserver Name>] - Vserver Name

Selects the 7-Mode LUNs in the specified Vserver.

[-path <path>] - LUN Path

Selects the 7-Mode LUNs with the specified path.

[-volume <volume name>] - Volume Name

Selects the 7-Mode LUNs that match the specified volume.

[-ostype <os_enum>] - OS Type

Selects the 7-Mode LUNs that match the specified operating system type.

[-size <size>] - LUN Size

Selects the 7-Mode LUNs that match the specified size.

[-prefix-size <size>] - Prefix Stream Size

Selects the 7-Mode LUNs that match the specified prefix stream size.

[-suffix-size <size>] - Suffix Stream Size

Selects the 7-Mode LUNs that match the specified suffix stream size.

[-serial <text>] - Serial Number

Selects the 7-Mode LUNs that match the specified serial number for clustered Data ONTAP. LUNs where `is-transitioned` is `false` do not have a serial number assigned for clustered Data ONTAP.

[-uuid <UUID>] - UUID

Selects the 7-Mode LUNs that match the specified UUID for clustered Data ONTAP. LUNs where `is-transitioned` is `false` do not have a UUID assigned for clustered Data ONTAP.
[-serial-7-mode <text>] - 7-mode Serial Number
Selects the 7-Mode LUNs that match the specified serial number from 7-Mode.

[-is-transitioned {true|false}] - Transition Complete
Selects the 7-Mode LUNs that match the specified transition state. LUNs where this value is true have been transitioned and are available to be mapped for client access. LUNs where this value is false have not yet been transitioned and may not be mapped.

[-vserver-uuid <UUID>] - Vserver UUID
Selects the 7-Mode LUNs that match the specified Vserver UUID.

[-node <nodename>] - Node
Selects the 7-Mode LUNs that match the specified node name.

Examples
The following example displays a summary of all 7-Mode LUNs for the volume vol1 in a Vserver named vs1:

```
cluster1:*> lun transition 7-mode show -vserver vs1 -volume vol1
Vserver   Path                         Type     Size   Transitioned
--------- ---------------------------- -------- ------ ------------
vs1       /vol/vol1/lun1               linux      10MB false
          /vol/vol1/lun2               linux     500MB true
          /vol/vol1/lun3               linux     500MB true
8 entries were displayed.
```

The following example displays detailed information for the 7-Mode LUN /vol/vol1/lun2 in a Vserver named vs1:

```
cluster1:*> lun transition 7-mode show -vserver vs1 -path /vol/vol1/lun2
Vserver Name: vs1
LUN Path: /vol/vol1/lun2
Volume Name: vol1
OS Type: linux
LUN Size: 500MB
Prefix Stream Size: 0
Suffix Stream Size: 0
Serial Number: BCVvv$DLZu8g
UUID: f33603b-9663-4567-9680-95c1a9cc6d9e
7-mode Serial Number: C4eqKotP18U1
Transition Complete: true
Vserver UUID: be4cc135-163f-11e3-931f-123478563412
Node: cluster-01
```

**metrocluster commands**

Manage MetroCluster

The metrocluster commands enable you to manage MetroCluster.

**metrocluster configure**

Configure MetroCluster and start DR mirroring for the node and its DR group

**Availability:** This command is available to cluster administrators at the admin privilege level.
Description
The `metrocluster configure` command creates a MetroCluster configuration on either all the nodes in both MetroCluster clusters or solely on nodes in a DR group. The command configures a HA partner, DR partner, and a DR auxiliary partner for the nodes and also starts NVRAM mirroring between the configured DR partner nodes.

In MetroCluster, a DR group is a group of four nodes, two in each of the MetroCluster clusters:

- In the local cluster, a node and its HA partner,
- In the peer cluster, a node and its HA partner. These nodes are DR partners to the nodes in the local cluster.

There can be several DR groups in the MetroCluster configuration. MetroCluster provides synchronous DR protection to all data sets belonging to nodes within a properly configured DR group.

Without the `--node` parameter, the `metrocluster configure` command configures all the DR groups in both the MetroCluster clusters.

With the `--node mynode` parameter, the command configures both the `mynode` node and its HA partner node from the local cluster, and its DR partner and DR auxiliary partner from the peer cluster.

Before running the `metrocluster configure` command, the aggregates and Vservers on each node must be prepared for the MetroCluster configuration. Each node should have:

- At least one non-root, mirrored aggregate of size greater than 10GB. This non-root aggregate should not have any volumes in it.
- No other non-root aggregates. Any other non-root, unmirrored aggregates and volumes should be deleted.
- No Vservers other than Vservers of type "node" or "admin." Any Vservers that are not of type "node" or "admin" should be deleted.
- A mirrored and healthy root aggregate.

After the command is successful all nodes in the local and remote clusters will have HA, DR, and DR auxiliary partners and NVRAM mirroring between the DR partners will be turned on. The same conditions apply for before running the `metrocluster configure --node mynode` command, except that only one DR group is configured.

Parameters

[-node-name (<nodename>|local)] - Node to Configure

This optional parameter specifies the name of a single node in the local cluster. The command creates MetroCluster configuration on the local node specified by this parameter and the three other nodes belonging to the same DR group.

[-refresh (true|false)] - Refresh Configuration (privilege: advanced)

This optional parameter specifies if the node partner configuration steps should be done again. Not specifying this parameter will cause the MetroCluster configuration to continue using the current node partner information.

[-allow-with-one-aggregate (true|false)] - Override the Two Data Aggregates Requirement (privilege: advanced)

This optional parameter specifies if MetroCluster configuration should be allowed with only one data aggregate in each cluster. This option has no effect if two or more aggregates are present.

Examples
The following example shows the creation of the MetroCluster configuration for a single DR group:

```
clusA::> metrocluster show
Cluster                  Configuration State     Mode
------------------------------- ---------------------- ------------------------
Local: clusA               not-configured        -
Remote: clusB              not-configured        -
```
clusA::> metrocluster node show
DR Group Cluster Node Configuration State Mirroring Mode
----- ------- ------------------ -------------- --------- --------------------
- clusA clusA-01 ready to configure - -
  clusA-02 ready to configure - -
  clusA-03 ready to configure - -
  clusA-04 ready to configure - -
4 entries were displayed.

clusA::> metrocluster configure -node clusA-01
[Job 45] Job succeeded: Configure is successful
CLUS::> metrocluster show
Cluster Configuration State Mode
----------------- ---------------------- ------------------------
Local: clusA partially-configured normal
Remote: clusB partially-configured normal
clusA::> metrocluster node show
DR Group Cluster Node Configuration State Mirroring Mode
----- ------- ------------------ -------------- --------- --------------------
- clusA clusA-03 ready to configure - -
  clusA-04 ready to configure - -
1 clusA clusA-01 configured enabled normal
  clusA-02 configured enabled normal
  clusB clusB-01 configured enabled normal
  clusB-02 configured enabled normal
6 entries were displayed.

The following example shows the creation of the MetroCluster configuration for all DR groups:

clusA::> metrocluster show
Cluster Configuration State Mode
----------------- ---------------------- ------------------------
Local: clusA not-configured -
Remote: clusB not-configured -
clusA::> metrocluster node show
DR Group Cluster Node Configuration State Mirroring Mode
----- ------- ------------------ -------------- --------- --------------------
- clusA clusA-01 ready to configure - -
  clusA-02 ready to configure - -
  clusA-03 ready to configure - -
  clusA-04 ready to configure - -
4 entries were displayed.
clusA::> metrocluster configure
[Job 45] Job succeeded: Configure is successful
clusA::> metrocluster show
Cluster Configuration State Mode
----------------- ---------------------- ------------------------
Local: clusA configured normal
Remote: clusB configured normal
clusA::> metrocluster node show
DR Group Cluster Node Configuration State Mirroring Mode
----- ------- ------------------ -------------- --------- --------------------
1 clusA clusA-01 configured enabled normal
  clusA-02 configured enabled normal

### metrocluster heal

Heal DR data aggregates and DR root aggregates

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**

The *metrocluster heal* command heals DR data aggregates and DR root aggregates in preparation for a DR switchback. You must issue this command twice to complete the two phases of the healing process: first to heal the aggregates by resynchronizing the mirrored plexes and then to heal the root aggregates by switching them back to the disaster site. The DR partner nodes must be powered off and remote disk shelves must be powered on before running this command.

**Parameters**

- **-phase (aggregates|root-aggregates)** - MetroCluster Healing Phase
  
  This parameter specifies the healing phase. The first phase, *aggregates*, heals aggregates by resynchronizing mirrored plexes. The second phase, *root-aggregates*, heals the root aggregates of partner nodes. Healing root aggregates switches them back to the disaster site, allowing the site to boot up.

- **[-override-vetoes [true]]** - Override All Soft Vetoes
  
  This optional parameter overrides almost all heal operation soft vetoes. If this optional parameter is set to true, the system overrides subsystem soft vetoes that might prevent the heal operation. Hard vetoes cannot be overridden and can still prevent the switchback operation.

**Examples**

The following example performs the healing of both the aggregates and root aggregates:

```
cluster1::> metrocluster heal -phase aggregates
[Job 136] Job succeeded: Heal Aggregates is successful

cluster1::> metrocluster heal -phase root-aggregates
[Job 137] Job succeeded: Heal Root Aggregates is successful
```

### metrocluster modify

Modify MetroCluster configuration options

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**

The *metrocluster modify* command modifies MetroCluster parameters for nodes in the MetroCluster configuration.
Parameters

{-auto-switchover-failure-domain <MetroCluster AUSO Failure Domain> - Cluster Level AUSO Option}

This parameter specifies configuration of the automatic switchover. Supported values are as follows:

- auso-on-cluster-disaster - triggers an unplanned switchover if all nodes in a DR cluster are down.
- auso-on-dr-group-disaster - triggers an unplanned switchover if both nodes of a DR group are down.
- auso-disabled - automatic switchover is disabled.

The default value is auso-on-cluster-disaster. It is set to default value if metrolcluster configure command is issued.

The auto-switchover failure domain is set to auso-disabled if the metrocluster unconfigure command is issued.

This setting only affects the local cluster where the command is run.

{-node-name <nodename>|local} - Node to Change the Option On

This parameter is used to specify the node in the cluster for which the parameter needs to be modified.

{-node-object-limit on|off} - Node Object Limit Option (privilege: advanced)

This parameter specifies whether the node-object-limit for the node is enforced or not. The possible values for this field are on or off and by default this option is set to on. The very first metcluster configure command for a node sets the option to on. If all the nodes in a DR group have this option enabled (the default state), then all the nodes in that DR group are protected from double failures.

A double failure is a scenario where a single node would require to serve data for more than one partner node. There are two double failure cases. In the first case, a switchover occurs (the first failure) followed by a local HA takeover within the surviving site (the second failure). For example, a failure at one site causes a switchover. Node A is on the surviving site and begins serving data for its DR partner. Now a failure occurs on a node A's HA partner, and node A takes over its HA partner. In the second case, a takeover has occurred (the first failure) followed by a switchover at the same site where takeover happened due to failure at partner site (the second failure). For example, a failure at one site causes a takeover at node A. Node A starts serving data for its HA partner node after takeover. Now a failure occurs at the partner site and node A switches over its DR partner. In both these double failure cases, node A must serve data for both its DR partner (on the failed site) and its local HA partner.

Note that an HA takeover followed by a disaster at the same site where the takeover happened it treated as a single failure.

If this option is disabled on any node in a DR group, all the nodes in that DR group are not protected from a double failure and nodes in the DR group would be unable to serve data for more than one partner node. In the case of a two-node cluster configuration, the failure of a node that is already in switchover mode can result the inability of the entire cluster (including the final surviving node) to serve data, resulting in client disruption.

If the metrocluster unconfigure command is issued, the option is set to off and the node continues to operate without being configured as part of the MetroCluster configuration.

This option cannot be modified on a two-node MetroCluster configuration.

{-automatic-switchover-onfailure [true]} - Node Level AUSO Option (privilege: advanced)

This parameter is used to enable automatic switchover on failure on a node when it is disabled because of internal errors. Possible value for this field is true. This option is available in diag mode and should be used only when warning ems message comes. All the nodes in MCC configuration must have this option enabled (the default state) to enable automatic switchover on failure.

Examples

The following example shows the output of Metrocluster modification done on a node:
clusA::*> metrocluster modify -node-name clusA-01 -node-object-limit on
[Job 168] Job succeeded: Modify is successful
clusA::*> metrocluster modify -node-name clusA-01 -automatic-switchover-onfailure false
[Job 308] Job succeeded: Modify is successful
clusA::> metrocluster modify -auto-switchover-failure-domain auso-on-cluster-disaster
[Job 308] Job succeeded: Modify is successful

---

**metrocluster show**

Display MetroCluster configuration information

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**
The *metrocluster show* command displays configuration information for the pair of clusters configured in MetroCluster. This command displays the following details about the local cluster and the DR partner cluster:

- **Configuration State:** This field specifies the configuration state of the cluster.
- **Mode:** This field specifies the operational mode of the cluster.
- **AUSO Failure Domain:** This field specifies the AUSO failure domain of the cluster.

**Parameters**

```
[-periodic-check-status]
```

If this option is used the MetroCluster periodic check status is displayed.

**Examples**
The following example shows the output of the command before MetroCluster configuration is done:

<table>
<thead>
<tr>
<th>Cluster</th>
<th>Entry Name</th>
<th>State</th>
</tr>
</thead>
<tbody>
<tr>
<td>Local: clusA</td>
<td>Configuration State: not-configured</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Mode: -</td>
<td></td>
</tr>
<tr>
<td>Remote: clusB</td>
<td>AUSO Failure Domain: -</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Configuration State: not-configured</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Mode: -</td>
<td></td>
</tr>
<tr>
<td></td>
<td>AUSO Failure Domain: -</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows the output of the command after MetroCluster configuration is done only for some DR groups:

<table>
<thead>
<tr>
<th>Cluster</th>
<th>Entry Name</th>
<th>State</th>
</tr>
</thead>
<tbody>
<tr>
<td>Local: clusA</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
The following example shows the output of the command after MetroCluster configuration is done:

```
clusA::> metrocluster show
Cluster                        Entry Name           State
------------------------------- -------------------  ---------------------
Local: clusA                  Configuration State configured
                                 Mode normal
                                 AUSO Failure Domain auso-on-cluster-disaster
Remote: clusB                  Configuration State configured
                                 Mode normal
                                 AUSO Failure Domain auso-on-cluster-disaster
```

The following example shows the output of the command in switchover mode:

```
clusA::> metrocluster show
Cluster                        Entry Name           State
------------------------------- -------------------  ---------------------
Local: clusA                  Configuration State configured
                                 Mode switchover
                                 AUSO Failure Domain auso-on-cluster-disaster
Remote: clusB                  Configuration State not-reachable
                                 Mode -
                                 AUSO Failure Domain not-reachable
```

The following example shows the output of the command when -periodic-check-status option is used:

```
clusA::> metrocluster show -periodic-check-status
Cluster                        Periodic Check Enabled
------------------------------- ----------------------
Local: clusA                  true
Remote: clusB                  true
```

**metrocluster switchback**

Switch back storage and client access

**Availability:** This command is available to cluster administrators at the `admin` privilege level.

**Description**
The `metrocluster switchback` command initiates the switchback of storage and client access from nodes in the DR site to their home nodes. The home nodes and storage shelves must be powered on and reachable by nodes in the DR site. The
**metrocluster heal** -phase aggregates and **metrocluster heal** -phase root-aggregates commands must have successfully completed before running the **metrocluster switchback** command.

### Parameters

- **[-override-vetoes | -f [true]]**  - Override All Soft Vetoes
  
  This optional parameter overrides all switchback operation soft vetoes. If this optional parameter is used, the system overrides subsystem soft vetoes that might prevent the switchback operation. Hard vetoes cannot be overridden and can still prevent the switchover operation.

- **[-simulate [true]]**  - Simulate Switchback (privilege: advanced)
  
  If this optional parameter is used, the system runs a simulation of the switchback operation to make sure all the prerequisites for the operation are met. This parameter cannot be used with switchback operations performed for switching back left-behind aggregates or for retrying a partially successful switchback.

### Examples

The following is an example of how to start the switchback operation.

```bash
clusA::> metrocluster switchback
```

---

**metrocluster switchover**

Switch over storage and client access

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**

The **metrocluster switchover** command initiates the switchover of storage and client access from the source cluster to the disaster recovery (DR) site. This command is to be used after a disaster that renders all the nodes in the source cluster unreachable and powered off. It can also be used for negotiated switchover when the outage of the source cluster is anticipated as in cases such as disaster recovery testing or a site going offline for maintenance. If a switchover operation previously failed on certain nodes on the DR site then issuing the command retries the operation on all of those nodes.

### Parameters

- **[-simulate [true]]**  - Simulate Negotiated Switchover (privilege: advanced)
  
  If this optional parameter is used, the system runs a simulation of the negotiated switchover operation to make sure all the prerequisites for the operation are met. This parameter cannot be used with switchover with the **-forced-on-disaster** parameter.

- **[-forced-on-disaster [true]]**  - Force Switchover on Disaster
  
  This optional parameter forces a switchover on disaster. This parameter should be used if all the nodes on the disaster stricken site are powered off and unreachable. In the absence of this parameter, the command attempts to perform a negotiated switchover operation.

- **[-force-nvfail-all [true]]**  - Sets in-nvfailed-state on All Volumes (privilege: advanced)
  
  If this parameter is used, the switchover command will set the in-nvfailed-state parameter to true for all volumes being switched over and will set the **-dr-force-nvfail** parameter to true for any volumes that do not already have it enabled. This parameter has no effect when performing a negotiated switchover.
[-retry-failed-nodes <Node name>, ...] - Nodes to Switchover

This optional parameter takes the list of nodes that previously failed the switchover operation and it retries the switchover operation on each of the nodes. This parameter is applicable only for a switchover with the -forced-on-disaster parameter.

[-override-vetoes [true]] - Override All Soft Vetoes

This optional parameter overrides all switchover operation soft vetoes. If this parameter is used, the system overrides all subsystem soft vetoes that might prevent the switchover operation. Hard vetoes cannot be overridden and can still prevent the switchover operation.

Examples

When a disaster strikes one site, the metrocluster switchover command is issued on the disaster recovery site as follows:

```
cluster1::> metrocluster switchover -forced-on-disaster true
Warning: MetroCluster switchover is a Disaster Recovery operation that could cause some data loss. The cluster on the other site must either be prevented from serving data or be simply powered off (nodes and disk shelves)
The following nodes (cluster1-01 cluster1-02) will participate in the switchover operation
Do you want to continue? [y|n]: y
Queued job. Use 'metrocluster operation show' to check status of the DR operation.
```

```
cluster1::> metrocluster operation show
Operation: switchover
  State: successful
  Start time: 10/3/2013 22:11:47
  End time: 10/3/2013 22:11:53
  Errors: -
```

metrocluster check commands

Check MetroCluster configuration and display results

metrocluster check disable-periodic-check

Disable Periodic Check

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The metrocluster check disable-periodic-check command disables the periodic checking of the MetroCluster configuration.

After this command is run, the MetroCluster Check job will be prevented from periodically checking the configuration for errors.
Examples

clusA::> metrocluster check disable-periodic-check

Related references

metrocluster check enable-periodic-check on page 222

metrocluster check enable-periodic-check

Enable Periodic Check

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The metrocluster check enable-periodic-check command enables the periodic checking of the MetroCluster configuration.

After this command is run, the MetroCluster Check job will able to run in the background and periodically check the configuration for errors.

Examples

clusA::> metrocluster check enable-periodic-check

Related references

metrocluster check disable-periodic-check on page 221

metrocluster check run

Check the MetroCluster setup

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The metrocluster check run command performs checks on the MetroCluster configuration and reports configuration errors if any.

To run this command, at least one DR group needs to be configured. The command checks the following parts of the configuration:

Node Configuration:

- node-reachable: This check verifies that the node is reachable.
- metrocluster-ready: This check verifies that the node is ready for MetroCluster configuration.
- local-ha-partner: This check verifies that the HA partner node is in the same cluster.
- ha-mirroring-on: This check verifies that HA mirroring for the node is configured.
- symmetric-ha-relationship: This check verifies that the relationship between the node and its HA partner is symmetric.
- remote-dr-partner: This check verifies that the DR partner node is in the remote cluster.
- dr-mirroring-on: This check verifies that DR mirroring for the node is configured.
- symmetric-dr-relationship: This check verifies that the relationship between the node and its DR partner is symmetric.
- remote-dr-auxiliary-partner: This check verifies that the DR auxiliary partner node is in the remote cluster.
- symmetric-dr-auxiliary-relationship: This check verifies that the relationship between the node and its DR auxiliary partner is symmetric.
- storage-failover-enabled: This check verifies that storage failover is enabled.
- has-intercluster-lif: This check verifies that the node has an intercluster LIF.
- node-object-limit: This check verifies that the node object limit option for the node is turned on.

Aggregate Configuration:
- mirroring-status: This check verifies that the aggregate is mirrored.
- disk-pool-allocation: This check verifies that the disks belonging to this aggregate have been correctly allocated to the right pools.

At the end of the check the command displays a summary of the results. This summary output can be viewed again by running `metrocluster check show`. If any of the rows in this output show any warnings more details can be viewed by running the `metrocluster check show` command for that component.

### Parameters

`[-skip-dr-simulation [true|false]]` - Skip the DR Readiness Checks (privilege: advanced)

If this optional parameter is set to true, the switchover and switchback simulations are not run.

### Examples

The following example shows the execution of the command when there are no warnings:

```
clusA::> metrocluster check run

Component           Result
-------------------  ---------
 nodes              ok
 clusters           ok
 lifs               ok
 config-replication ok
 aggregates         ok

5 entries were displayed.

Command completed. Use the "metrocluster check show -instance" command or sub-commands in "metrocluster check" directory for detailed results.
```

The following example shows the execution of the command when there are some warnings:

```
clusA::> metrocluster check run

Component           Result
-------------------  ---------
 nodes              warning
 clusters           ok
 lifs               ok
 config-replication ok
 aggregates         ok

5 entries were displayed.
```

metrocluster check commands
Command completed. Use the "metrocluster check show -instance" command or sub-commands in "metrocluster check" directory for detailed results.

**metrocluster check show**

Show the results of the last instance of MetroCluster check

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**

The `metrocluster check show` command displays the results of `metrocluster check run` command.

This command displays the high-level verification results for each of the components. If there any errors for a component, running the show command for that component (for example `metrocluster check node show` or `metrocluster check aggregate show`) will display more information about the warning.

**Note:** Please note that this command does not run the checks but only displays the results of checks. To look at the latest results, run the `metrocluster check run` command and then run this command.

**Parameters**

```
[-fields <fieldname>, ...]
```

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

```
[-instance]
```

If you specify the `-instance` parameter, the command displays detailed information about all fields.

```
[-timestamp <MM/DD/YYYY HH:MM:SS>] - Time of Check
```

This is the time at which the `metrocluster check run` command was last run in this cluster and these results were produced. If this parameter is specified, only rows with this timestamp will be displayed.

```
[-component <MetroCluster Check Components>] - Name of the Component
```

This is the name of the component. If this parameter is specified, only rows with this component will be displayed.

```
[-result {ok|warning|not-run|not-applicable}] - Result of the Check
```

This is the result of the check for the component. If this parameter is specified, only rows with this result will be displayed.

```
[-additional-info <text>] - Additional Information/Recovery Steps
```

This is the additional info for the verification for this component. This field will have detailed information about the warning and recovery steps. If this parameter is specified, only rows with this additional info will be displayed.
Examples

The following example shows the execution of the command when there are no warnings:

```
clusA::> metrocluster check show
Component           Result
------------------- ---------
nodes               ok

**metrocluster check cluster commands**

The cluster directory

**metrocluster check cluster show**

Show results of MetroCluster check for the cluster components

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**

The `metrocluster check cluster show` command displays the results of cluster checks performed by the `metrocluster check run` command.

**Parameters**

```
[-fields <fieldname>, ...]
```

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

```
|--instance]
```

If you specify the `-instance` parameter, the command displays detailed information about all fields.

```
[-check {negotiated-switchover-ready|switchback-ready|job-schedules|licenses|periodic-check-enabled}] - Type of Check
```

This is the type of the check performed. If this parameter is specified, only rows with this check will be displayed.

```
[-cluster <Cluster name>] - Cluster Name
```

This is the name of the cluster the check results apply to. If this parameter is specified, only rows matching the specified cluster will be displayed.

```
[-result {ok|warning|not-run|not-applicable}] - Result of the Check
```

This is the result of the check. If this parameter is specified, only rows with this result will be displayed.

```
[-additional-info <text>] - Additional Information/Recovery Steps
```

This is additional information about the check. This field has more information and recovery steps for the warning. If this parameter is specified, only rows with this additional info will be displayed.

**Examples**

The following example shows the execution of the command in a MetroCluster configuration:

```
clusA::> metrocluster check cluster show

<table>
<thead>
<tr>
<th>Cluster</th>
<th>Check</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>clusA</td>
<td>negotiated-switchover-ready</td>
<td>ok</td>
</tr>
<tr>
<td></td>
<td>switchback-ready</td>
<td>not-applicable</td>
</tr>
</tbody>
</table>
```

**metrocluster check aggregate commands**

The aggregate directory

**metrocluster check aggregate show**

Show results of MetroCluster check for aggregates

**Availability:** This command is available to cluster administrators at the *admin* privilege level.

**Description**

The *metrocluster check aggregate show* command displays the results of aggregate checks performed by the *metrocluster check run* command.

The command verifies the following aspects of the configuration of all aggregates in MetroCluster:

- mirroring-status: This check verifies that the aggregate is mirrored.
- disk-pool-allocation: This check verifies that the disks belonging to this aggregate have been correctly allocated to the right pools.

Additional information about the warnings (if any) and recovery steps can be viewed by running the command with the `-instance` option.

**Parameters**

```
{ [-fields <fieldname>, ...]  
  If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use `-fields ?' to display the fields to specify.  
| [-instance]  
  If you specify the -instance parameter, the command displays detailed information about all fields.  
]-node <Node name> - Node Name  
  This is the name of the node for which the check was run. If this parameter is specified, only rows with this node will be displayed.  
]-aggregate <aggregate name> - Name of the Aggregate  
  This is the name of the aggregate for which the check was run. If this parameter is specified, only rows with this aggregate will be displayed.  
]-check <MetroCluster Aggregate Check> - Type of Check  
  This is the type of the check performed. If this parameter is specified, only rows with this check will be displayed.  
```

---

| job-schedules | ok  
| licenses      | ok  
| clusB         |  
| negotiated-switch-ready | ok  
| switchback-ready      | not-applicable  
| job-schedules | ok  
| licenses      | ok  

8 entries were displayed.
[<cluster name>] - Name of Cluster

This is the name of the cluster the node belongs to. If this parameter is specified, only rows with this cluster will be displayed.

[-result {ok|warning|not-run|not-applicable}] - Result of the Check

This is the result of the check. If this parameter is specified, only rows with this result will be displayed.

[-additional-info <text>, ...] - Additional Information/Recovery Steps

This is additional information about the check. This field has more information and recovery steps for the warning. If this parameter is specified, only rows with this additional info will be displayed.

Examples

The following example shows the execution of the command in a MetroCluster configuration with two nodes per cluster:

```
clusA::> metrocluster check aggregate show
Node                  Aggregate             Check                 Result
--------------------- --------------------- --------------------- ---------
clusA-01              a1_required_data_aggr
                       mirroring-status ok
disk-pool-allocation ok
clusA-02              a2_required_data_aggr
                       mirroring-status ok
disk-pool-allocation ok
clusB-01              b1_required_data_aggr
                       mirroring-status ok
disk-pool-allocation ok
clusB-02              aggr0_b2
                       mirroring-status ok
disk-pool-allocation ok
CLUSB-01              b2_required_data_aggr
                       mirroring-status ok
disk-pool-allocation ok
16 entries were displayed.
```

The following example shows the execution of the command with -instance option:

```
clusA::> metrocluster check aggregate show -instance
Node Name: clusA-01
Name of the Aggregate: a1_required_data_aggr_1
Type of Check: mirroring-status

**metrocluster check config-replication commands**

Display MetroCluster check configuration replication status

**metrocluster check config-replication show**

Display MetroCluster config-replication status information

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**
The `metrocluster check config-replication show` command displays the results of MetroCluster configuration replication.

The command verifies the following aspects of MetroCluster configuration replication:

- **Enabled:** Verifies that MetroCluster configuration replication is enabled on the cluster.
- **Running:** Verifies that MetroCluster configuration replication is running on the cluster.
- **Remote Heartbeat:** Verifies that the MetroCluster configuration replication heartbeat with the remote cluster is healthy.
- **Last Heartbeat Sent:** Prints the timestamp of the last MetroCluster configuration replication heartbeat sent to the remote cluster.
- **Last Heartbeat Received:** Prints the timestamp of the last MetroCluster configuration replication heartbeat received from the remote cluster.
- **Storage Status:** Verifies that MetroCluster configuration replication storage is healthy.
- **Storage In Use:** Prints the location of MetroCluster configuration replication storage.
- **Storage Remarks:** Prints the underlying root cause for non healthy MetroCluster configuration storage.
- **Vserver Streams:** Verifies that MetroCluster configuration replication Vserver streams are healthy.
- **Cluster Streams:** Verifies that MetroCluster configuration replication Cluster streams are healthy.

Additional information about the warnings (if any) and recovery steps can be viewed by running the command with the -instance option.

**Parameters**

[-instance]

If you specify the -instance parameter, the command displays detailed information about all fields.

**Examples**
The following example shows the output of `metrocluster check config-replication show`:

```
clusA::metrocluster check config-replication> show
  Enabled: true
  Running: true
  Remote Heartbeat: ok
  Last Heartbeat Sent: 12/12/2013 14:24:59
  Last Heartbeat Received: 12/12/2013 14:25:00
  Storage Status: ok
  Storage Remarks: ok
  Storage In Use: Cluster-wide Volume: MDV_CRS_1bc7134a5ddf11e3b63f123478563412_A
```

**metrocluster check config-replication show-aggregate-eligibility**

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**

The `metrocluster check config-replication show-aggregate-eligibility` command displays the MetroCluster configuration replication aggregate eligibility.

**Parameters**

```
[-fields <fieldname>, ...]
```

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

```
[-instance ]
```

If you specify the `-instance` parameter, the command displays detailed information about all fields.

```
[-aggregate <aggregate name>] - Aggregate
```

This is the aggregate name. If this parameter is specified, only rows with this aggregate will be displayed.

```
[-hosted-configuration-replication-volumes <volume name>, ...] - Currently Hosted Configuration Replication Volumes
```

This is the list of the configuration replication volumes hosted on this aggregate. If this parameter is specified, only rows with these configuration replication volumes will be displayed.

```
[-is-eligible-to-host-additional-volumes (true|false)] - Eligibility to Host Another Configuration Replication Volume
```

This is the eligibility of the aggregate to host additional configuration replication volumes. If this parameter is specified, only rows with this eligibility will be displayed.

```
[-comment <text>] - Comment for Eligibility Status
```

This is a comment regarding the eligibility of the aggregate to host configuration replication volumes. If this parameter is specified, only rows with this comment will be displayed.

**Examples**

The following example shows the execution of the command in a MetroCluster configuration with thirteen aggregates in the cluster:

```
clusA:~$ metrocluster check config-replication> show-aggregate-eligibility

<table>

metrocluster check config-replication show-capture-status

Display MetroCluster capture status information

Availability: This command is available to cluster administrators at the advanced privilege level.

Description

The metrocluster check config-replication show-capture-status command indicates whether or not a configuration change that would prevent a negotiated switchover is currently being captured for replication.

Examples

The following example shows the execution of the command in a MetroCluster configuration when capture is not in progress:

```
cluster1::*> metrocluster check config-replication show-capture-status
Is Capture in Progress: false
```

metrocluster check lif commands

Display LIF placement check results in MetroCluster configuration

metrocluster check lif repair-placement

Repair LIF placement for the sync-source Vserver LIFs in the destination cluster

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The metrocluster check lif repair-placement command reruns LIF placement for those LIFs displayed by the metrocluster check lif show command. This command is expected to be run after the admin manually rectifies the LIF
placement failures displayed in the `metrocluster check lif show` command output. The command is successful if the LIF placement rerun does not encounter any LIF placement failure. This is to be confirmed by subsequent running of the `metrocluster check lif show`.

**Parameters**

- **-vserver <Vserver Name>** - sync-source Vserver Name
  
  This is the name of the sync source Vserver that has LIF placement failures as reported by the `metrocluster check lif show` command. This input ensures that the command is run on the specified Vserver.

- **[-lif <lif-name>]** - Logical Interface Name
  
  This is the Logical Interface name that belongs to the sync source Vserver that has a LIF placement failure in the destination cluster as reported by the `metrocluster check lif show` command. This input ensures that the command is run on the specified LIF only.

**Examples**

The following example shows the execution of the command with a sync source Vserver and a LIF specified:

```
clusA::> metrocluster check lif repair-placement -vserver vs1.example.com -lif fcplif1
Command completed. Run the "metrocluster check lif show" command for results.
clusA::> metrocluster check lif repair-placement -vserver vs1.example.com -lif iscsilif1
Command completed. Run the "metrocluster check lif show" command for results.
```

The following example shows the execution of the command with only a sync-source Vserver specified:

```
clusA::> metrocluster check lif repair-placement -vserver vs1.example.com
Command completed. Run the "metrocluster check lif show" command for results.
clusA::>
```

**Related references**

`metrocluster check lif show` on page 233

**metrocluster check lif show**

Show results of MetroCluster check results for the data LIFs

**Availability:** This command is available to `cluster` administrators at the `admin` privilege level.

**Description**

The `metrocluster check lif show` command displays the LIF placement failures in the MetroCluster configuration. The command verifies the following aspects of the LIF placements of all the data LIFs in Metrocluster:

- lif-placed-on-dr-node: This check verifies that the LIF is placed on DR partner node.
- port-selection: This check verifies that the LIF is placed on correct port.

The LIF placement failures are mostly fabric/network connectivity issues that require manual intervention. Once the connectivity issues are resolved manually, the admin is expected to run `metrocluster check lif repair-placement` command to resolve the LIF placement issues for the sync source Vserver.

Additional information about the warnings (if any) and recovery steps can be viewed by running the command with the `-instance` option.
Parameters

`{-fields <fieldname>,...}`

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

`{-instance}`

If you specify the `-instance` parameter, the command displays detailed information about all fields.

`{-cluster <Cluster name>}` - Cluster Name

This is the name of the cluster the LIF belongs to. If this parameter is specified, only rows with this cluster will be displayed.

`{-cluster-uuid <UUID>}` - Cluster UUID

This is the uuid of the cluster the LIF belongs to.

`{-vserver <text>}` - Name of the Vserver

This is the name of the Vserver in the MetroCluster configuration

`{-lif <lif-name>}` - Name of the lif

This is the name of the LIF.

`{-check <MetroCluster LIF placement Check>}` - Description

This is the type of the check performed. If this parameter is specified, only rows with this check will be displayed.

`{-result {ok|warning|not-run|not-applicable}}` - Result of the check

This is the result of the check performed. If this parameter is specified, only rows with this result will be displayed.

`{-additional-info <text>}` - Additional information/Recovery steps

This is additional information about the check. This field has more information and recovery steps for the warning. If this parameter is specified, only rows with this additional info will be displayed.

**metrocluster check node commands**

The node directory

**metrocluster check node show**

Show results of MetroCluster check for nodes

**Availability:** This command is available to cluster administrators at the `admin` privilege level.

**Description**

The `metrocluster check node show` command displays the results of node checks performed by the `metrocluster check run` command.

The command verifies the following aspects of the configuration of all nodes in MetroCluster:

- **node-reachable:** This check verifies that the node is reachable.
- **metrocluster-ready:** This check verifies that the node is ready for MetroCluster configuration.
- **local-ha-partner:** This check verifies that the HA partner node is in the same cluster.
- **ha-mirroring-on:** This check verifies that HA mirroring for the node is configured.
- **ha-mirroring-op-state:** This check verifies that the HA mirroring operation is online.
- **symmetric-ha-relationship:** This check verifies that the relationship between the node and its HA partner is symmetric.
- **remote-dr-partner:** This check verifies that the DR partner node is in the remote cluster.
- **dr-mirroring-on:** This check verifies that DR mirroring for the node is configured.
- **dr-mirroring-op-state:** This check verifies that the DR mirroring operation is online.
- **symmetric-dr-relationship:** This check verifies that the relationship between the node and its DR partner is symmetric.
- **remote-dr-auxiliary-partner:** This check verifies that the DR auxiliary partner node is in the remote cluster.
- **symmetric-dr-auxiliary-relationship:** This check verifies that the relationship between the node and its DR auxiliary partner is symmetric.
- **storage-failover-enabled:** This check verifies that storage failover is enabled.
- **has-intercluster-lif:** This check verifies that the node has an intercluster LIF.
- **node-object-limit:** This check verifies that the node object limit option for the node is turned on.

Additional information about the warnings (if any) and recovery steps can be viewed by running the command with the `-instance` option.

**Parameters**

`[-fields <fieldname>, ...]`

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `'-fields ?'` to display the fields to specify.

`[-instance ]]`

If you specify the `-instance` parameter, the command displays detailed information about all fields.
[\-node <Node name>] - Node Name

This is the name of the node for which the check was run. If this parameter is specified, only rows with this node will be displayed.

[\-check <MetroCluster Node Check>] - Type of Check

This is the type of the check performed. If this parameter is specified, only rows with this check will be displayed.

[\-cluster <Cluster name>] - Cluster Name

This is the name of the cluster the node belongs to. If this parameter is specified, only rows with this cluster will be displayed.

[\-result {ok|warning|not-run|not-applicable}] - Result of the Check

This is the result of the check. If this parameter is specified, only rows with this result will be displayed.

[\-additional-info <text>] - Additional Information/Recovery Steps

This is additional information about the check. This field has more information and recovery steps for the warning. If this parameter is specified, only rows with this additional info will be displayed.

**metrocluster config-replication commands**

Display configuration replication information

**metrocluster config-replication cluster-storage-configuration commands**

Display configuration replication storage configuration

**metrocluster config-replication cluster-storage-configuration modify**

Modify MetroCluster storage configuration information

**Availability:** This command is available to cluster administrators at the advanced privilege level.

**Description**
The metrocluster config-replication cluster-storage-configuration modify command modifies the configuration of storage used for configuration replication.

**Parameters**

- `-disallowed-aggregates <aggregate name>, ...` - Disallowed Aggregates
  Use this parameter to set the list of storage aggregates that are not available to host storage for configuration replication.
Examples
The following example disallows two aggregates named `aggr1` and `aggr2`:

```
cluster1:~> metrocluster config-replication cluster-storage-configuration modify -disallowed-aggregates aggr1,aggr2
```

**metrocluster config-replication cluster-storage-configuration show**
Display MetroCluster storage configuration information

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

**Description**
The `metrocluster config-replication cluster-storage-configuration show` command shows details of the configuration of the storage used for configuration replication.

The information displayed is the following:

- **Disallowed Aggregates** - The list of storage aggregates that are configured as not allowed to host storage areas.
- **Auto-Repair** - Displays `true` if the automatic repair of storage areas used by configuration replication is enabled.
- **Auto-Recreate** - Displays `true` if the automatic recreation of storage volumes used by configuration replication is enabled.
- **Use Mirrored Aggregate** - Displays `true` if storage areas for configuration replication are to be hosted on a mirrored aggregate.

Examples
The following is an example of the `metrocluster config-replication cluster-storage-configuration show` command:

```
cluster1:~> metrocluster config-replication cluster-storage-configuration show
    Disallowed Aggregates: -
    Auto-Repair: true
    Auto-Recreate: true
    Use Mirrored Aggregate: true
```

**metrocluster config-replication resync-status commands**
Display MetroCluster configuration synchronization status

**metrocluster config-replication resync-status show**
Display MetroCluster Configuration Resynchronization Status

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.
Description
The `metrocluster config-replication resync-status show` command displays the state of the configuration synchronization operation between the two clusters in the MetroCluster configuration.

This command displays the following details about the local cluster and the peer cluster:

- Source: This is the source side whose configuration is being replicated to the destination side.
- Destination: This is the destination side where the configuration is being replicated to from the source side.
- State: This is the state of the synchronization operation.
- % Complete: This is completion percentage of the operation.

Examples
The following example shows the output of the command when synchronization is in progress:

```
clusterA::> metrocluster config-replication resync-status show
Source                  Destination             State       % Complete
----------------------- ----------------------- ----------- ----------
clusterA                clusterB                complete    -
clusterB                clusterA                complete    -
```

The following example shows the output of the command when synchronization from clusB to clusA is in progress:

```
clusA::> metrocluster config-replication resync-status show
Source                  Destination             State       % Complete
----------------------- ----------------------- ----------- ----------
clusterA                clusterB                complete    -
clusterB                clusterA                messaging   95
```

`metrocluster interconnect commands`
MetroCluster interconnect commands

`metrocluster interconnect adapter commands`
Manage MetroCluster interconnect adapters

`metrocluster interconnect adapter modify`
Modify MetroCluster interconnect adapter settings

Availability: This command is available to cluster administrators at the `advanced` privilege level.

Description
The `metrocluster interconnect adapter modify` command enables you to modify settings of the MetroCluster interconnect adapter.
Parameters

- **node (<nodename>|local) - Node Name**
  
  This parameter specifies the node name.

- **is-ood-enabled {true|false} - Is Out-of-Order Delivery Enabled?**
  
  This parameter specifies the out-of-order delivery setting on the adapter.

Examples

The following example enables out-of-order delivery for the port 'fcvi_device_0' on the node 'clusA-01':

```
clusA::*> metrocluster interconnect adapter modify -node clusA-01 -adapter-port-name fcvi_device_0 -is-ood-enabled true
```

**metrocluster interconnect adapter show**

Display MetroCluster interconnect adapter information

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**

The `metrocluster interconnect adapter show` command displays interconnect adapter information for the nodes in a MetroCluster configuration.

This command displays the following details about the local node and the HA partner node:

- **Node:** This field specifies the name of the node in the cluster.
- **Adapter Name:** This field specifies the name of the interconnect adapter.
- **Adapter Type:** This field specifies the type of the interconnect adapter.
- **Link Status:** This field specifies the physical link status of the interconnect adapter.
- **Is OOD Enabled:** This field specifies the out-of-order delivery status of the interconnect adapter.
- **IP Address:** This field specifies the IP address assigned to the interconnect adapter.
- **Port Number:** This field specifies the port number of the interconnect adapter.

**Parameters**

```
| [-fields <fieldname>, ...] |
| [-connectivity] |
| [-switch] |
| [-connectivity-hidden] (privilege: advanced) |
| [-instance] |
```

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

| `-connectivity` |

Displays the connectivity information from all the interconnect adapters to the connected nodes.

| `-switch` |

Displays details of switches connected to all the interconnect adapters.

| `-connectivity-hidden` (privilege: advanced) |

Displays additional connectivity information (IP address, Area ID, Port ID) from all the interconnect adapters to the connected nodes.

| `-instance` |

If you specify the `-instance` parameter, the command displays detailed information about all fields.
[-node {<nodename>|local}] - Node Name
Displays information only about the interconnect adapters that are hosted by the specified node.

[-adapter <text>] - Adapter
Displays information only about the interconnect adapters that match the specified name.

[-port-name <text>] - Port Name
Displays information only about the interconnect adapters that host the specified port name.

[-type <text>] - Adapter Type
Displays information only about the interconnect adapters that match the specified adapter type.

[-physical-status <text>] - Physical Status
Displays information only about the interconnect adapters that match the specified physical status.

[-wwn <text>] - Adapter Port World Wide Name
Displays information only about the interconnect adapters that match the specified world wide name.

[-address <text>] - IP Address
Displays information only about the interconnect adapters that match the specified IP address.

[-firmware-version <text>] - Firmware Version
Displays information only about the interconnect adapters that match the specified firmware version.

[-link-speed <text>] - Link Speed
Displays information only about the interconnect adapters that match the specified link speed.

[-link-speed-neg-type <text>] - Link Speed Negotiation Type
Displays information only about the interconnect adapters that match the specified negotiated link speed type.

[-switch-name <text>] - Switch Name
Displays information only about the interconnect adapters that are connected to the specified switch.

[-switch-model <text>] - Switch Model
Displays information only about the interconnect adapters that are connected to the switch with the specified model.

[-switch-wwn <text>] - Switch WWName
Displays information only about the interconnect adapters that are connected to the switch with the specified world wide name.

[-switch-vendor <text>] - Switch Vendor
Displays information only about the interconnect adapters that are connected to the switch with the specified vendor.

[-switch-status <text>] - Switch Status
Displays information only about the interconnect adapters that are connected to the switch with the specified operational status.

[-switch-port-number <text>] - Switch Port Number
Displays information only about the interconnect adapters that are connected to the switch with the specified port number.

[-switch-port-wwpn <text>] - Switch Port WWPN
Displays information only about the interconnect adapters that are connected to the switch with the specified word wide port name.

[-remote-adapters-name-list <text>,... ] - Remote Adapter Name List
Displays information only about the interconnect adapters that are connected to the specified remote adapters.
[-remote-adapter-wwn-list <text>, ...] - Remote Adapter WWName List
Displays information only about the interconnect adapters that are connected to the remote adapters with the specified world wide names.

[-remote-adapter-address-list <text>, ...] - Remote Adapter IP Address List
Displays information only about the interconnect adapters that are connected to the remote adapters with the specified IP addresses.

[-remote-adapter-port-id-list <Hex Integer>, ...] - Remote Adapter Port ID List
Displays information only about the interconnect adapters that are connected to the remote adapters with the specified port IDs.

[-remote-adapter-domain-id-list <integer>, ...] - Remote Adapter Domain ID List
Displays information only about the interconnect adapters that are connected to the remote adapters with the specified domain IDs.

[-remote-adapter-area-id-list <integer>, ...] - Remote Adapter Area ID List
Displays information only about the interconnect adapters that are connected to the remote adapters with the specified Area IDs.

[-remote-partner-system-id-list <integer>, ...] - Remote Partner System ID List
Displays information only about the interconnect adapters that are connected to the remote nodes with the specified System IDs.

[-remote-partner-name-list (<nodename>|local), ...] - Remote Partner Name List
Displays information only about the interconnect adapters that are connected to the specified remote nodes.

[-is-ood-enabled {true|false}] - Is Out-of-Order Delivery Enabled?
Displays information only about the interconnect adapters that match the specified out-of-order delivery setting.

### Examples

The following example shows the output of the command during normal operation (neither cluster is in switchover state):

```
clusA::> metrocluster interconnect adapter show

metrocluster interconnect mirror commands

Manage MetroCluster interconnect mirrors

metrocluster interconnect mirror show

Display MetroCluster interconnect mirror information

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The metrocluster interconnect mirror show command displays NVRAM mirror information for the nodes configured in a MetroCluster.

This command displays the following details about the local node and the HA partner node:

- Node: This field specifies the name of the node in the cluster.
- Partner Name: This field specifies the name of the partner node.
- Partner Type: This field specifies the type of the partner.
- Mirror Admin Status: This field specifies the administrative status of the NVRAM mirror between partner nodes.
- Mirror Oper Status: This field specifies the operational status of the NVRAM mirror between partner nodes.
- Adapter: This field specifies the name of the interconnect adapter used for NVRAM mirroring.
- Type: This field specifies the type of the interconnect adapter used for NVRAM mirroring.
- Status: This field specifies the physical status of the interconnect adapter used for NVRAM mirroring.

Parameters

text

- **-fields <fieldname>, ...**
  
  If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

- **-instance**
  
  If you specify the -instance parameter, the command displays detailed information about all fields.

- **-node <nodename>|local** - Node Name
  
  If this parameter is specified, mirror details of the specified node are displayed.

- **-partner-type {HA|DR|AUX}** - Partner Type
  
  If this parameter is specified, mirror details of the specified partner type are displayed.

- **-adapter <text>** - Adapter
  
  If this parameter is specified, mirror details of the specified adapter are displayed.

- **-type <text>** - Adapter Type
  
  If this parameter is specified, mirror details of the specified adapter type are displayed.

- **-status <text>** - Status
  
  If this parameter is specified, mirror details of the specified adapter with the specified status are displayed.

- **-mirror-oper-status {unknown|online|offline}** - Mirror Operational Status
  
  If this parameter is specified, only mirror details with the specified operational status are displayed.

- **-partner-name <text>** - Partner Name
  
  If this parameter is specified, mirror details of the specified partner are displayed.
[\(-\text{mirror-admin-status \{enabled\|disabled\}}\) - Mirror Administrative Status]

If this parameter is specified, only mirror details with the specified administrative status are displayed.

**Examples**

The following example shows the output of the command during normal operation (neither cluster is in switchover state):

```
clusA::> metrocluster interconnect mirror show
Mirror   Mirror
Partner Admin    Oper
Node Partner Name Type    Status   Status  Adapter Type   Status
---- ------------ ------- -------- ------- ------- ------ -----
clusA-01
clusA-02
HA   enabled online cxgb3_0 iWARP Up
clusB-01
DR enabled online fcvi_device_0
clusA-02
clusA-01
HA   enabled online cxgb3_0 iWARP Up
clusB-02
DR enabled online fcvi_device_0
clusA-02
clusA-01
HA   enabled online cxgb3_0 iWARP Up
clusB-02
DR enabled online fcvi_device_0
```

The following example shows the output of the command after MetroCluster switchover is performed:

```
clusA::> metrocluster interconnect mirror show
Mirror   Mirror
Partner Admin    Oper
Node Partner Name Type    Status   Status  Adapter Type   Status
---- ------------ ------- -------- ------- ------- ------ -----
clusA-01
clusA-02
HA   enabled online cxgb3_0 iWARP Up
clusB-01
DR disabled offline fcvi_device_0
clusA-02
clusA-01
HA   enabled online cxgb3_0 iWARP Up
clusB-02
DR disabled offline fcvi_device_0
clusA-02
clusA-01
HA   enabled online cxgb3_0 iWARP Up
clusB-02
DR disabled offline fcvi_device_0
```
**metrocluster interconnect mirror multipath commands**

Manage MetroCluster interconnect mirror multipath policy

**metrocluster interconnect mirror multipath show**

Display multipath information

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**

The `metrocluster interconnect mirror multipath show` command displays the NVRAM mirror multipath policy for the nodes configured in a MetroCluster.

This command displays the following details about the local node and the HA partner node:

- **Node:** This field specifies the name of the node in the cluster.
- **Multipath Policy:** This field specifies the multipath policy used for NVRAM mirroring.

**Parameters**

```
[-fields <fieldname>, ...]
```

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

```
[-instance]
```

If you specify the `-instance` parameter, the command displays detailed information about all fields.

```
[-node {<nodename>|local}] - Node Name
```

If this parameter is specified, mirror details of the specified node are displayed.

```
[-multipath-policy {no-mp|static-map|dynamic-map|round-robin}] - Multipath Policy
```

If this parameter is specified, nodes with the specified multipath policy are displayed.

**Examples**

The following example shows the output of the command:

```
clusA::> metrocluster interconnect mirror multipath show
Node            Multipath Policy
--------------- -----------------
clusA-1         static-map
clusA-2         static-map
```

**metrocluster node commands**

Display MetroCluster nodes

**metrocluster node show**

Display MetroCluster node configuration information

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.
Description
The `metrocluster node show` command displays configuration information for the nodes in the MetroCluster configuration.

Parameters

```
[-fields <fieldname>, ...]
```

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

```
[-partners]
```

If this option is used the MetroCluster node partnership view will be displayed.

```
[-instance]
```

If you specify the `-instance` parameter, the command displays detailed information about all fields.

```
[-dr-group-id <integer>] - DR Group ID
```

If this parameter is specified, all nodes belonging to the specified DR group are displayed.

```
[-cluster <Cluster name>] - Cluster Name
```

If this parameter is specified, all nodes belonging to the specified cluster are displayed.

```
[-node <Node name>] - Node Name
```

If this parameter is specified, the specified node is displayed.

```
[-ha-partner <Node name>] - HA Partner Name
```

If this parameter is specified, the node with the specified HA partner is displayed.

```
[-dr-cluster <Cluster name>] - DR Cluster Name
```

If this parameter is specified, all nodes belonging to the specified cluster are displayed.

```
[-dr-partner <Node name>] - DR Partner Name
```

If this parameter is specified, all nodes belonging to the specified cluster are displayed.

```
[-dr-auxiliary <Node name>] - DR Auxiliary Name
```

If this parameter is specified, the node with the specified DR auxiliary partner is displayed.

```
[-node-uuid <UUID>] - Node UUID
```

If this parameter is specified, the node with the specified Uuid is displayed.

```
[-ha-partner-uuid <UUID>] - HA Partner UUID
```

If this parameter is specified, the nodes with the specified HA partner is displayed.

```
[-dr-partner-uuid <UUID>] - DR Partner UUID
```

If this parameter is specified, the nodes with the specified DR partner is displayed.

```
[-dr-auxiliary-uuid <UUID>] - DR Auxiliary UUID
```

If this parameter is specified, the nodes with the specified DR auxiliary partner is displayed.

```
[-node-cluster-uuid <UUID>] - Node Cluster UUID
```

If this parameter is specified, all nodes belonging to the specified cluster are displayed.

```
[-ha-partner-cluster-uuid <UUID>] - HA Partner Cluster UUID
```

If this parameter is specified, all nodes whose HA partner belong to the specified cluster are displayed.

```
[-dr-partner-cluster-uuid <UUID>] - DR Partner Cluster UUID
```

If this parameter is specified, all nodes whose DR partner belong to the specified cluster are displayed.

```
[-dr-auxiliary-cluster-uuid <UUID>] - DR Auxiliary Cluster UUID
```

If this parameter is specified, all nodes whose DR auxiliary partner belong to the specified cluster are displayed.
[−node−systemid <integer>] - Node System ID
   If this parameter is specified, all nodes with the specified system ID are displayed.

[−ha−partner−systemid <integer>] - HA Partner System ID
   If this parameter is specified, all nodes with an HA partner with the specified system ID are displayed.

[−dr−partner−systemid <integer>] - DR Partner System ID
   If this parameter is specified, all nodes with a DR partner with the specified system ID are displayed.

[−dr−auxiliary−systemid <integer>] - DR Auxiliary System ID
   If this parameter is specified, all nodes with a DR auxiliary partner with the specified system ID are displayed.

[−dr−mirroring−state <text>] - State of DR Mirroring Config
   If this parameter is specified, all nodes with this field set to the specified value are displayed. This field specifies if the NVRAM mirroring to the DR partner is enabled through the `metrocluster configure` command. This field needs to be set to "enabled" for the DR mirroring to be active.

[−configuration−state <text>] - Configuration State of Node
   If this parameter is specified, all nodes with this field set to the specified value are displayed.

[−additional−configuration−info <text>] - Additional Configuration Info
   If this parameter is specified, all nodes with this field set to the specified value are displayed.

[−dr−operation−state <text>] - DR Operation State
   If this parameter is specified, all nodes with this field set to the specified value are displayed.

[−dr−operation−time <integer>] - Time to Complete Operation (secs)
   If this parameter is specified, all nodes with this field set to the specified value are displayed.

[−node−object−limit {on|off}] - Specifies if the Node Object Limits are Enforced
   If this parameter is specified, all nodes with this field set to the specified value are displayed.

[−node−ha−partner <text>] - Node and its HA Partner
   If this parameter is specified, all nodes with this field set to the specified value are displayed.

[−automatic−uso {true|false}] - Automatic USO (privilege: advanced)
   If this parameter is specified, all nodes with this field set to the specified value are displayed.

**Examples**

The following example shows the output of the command before the MetroCluster configuration is done:

```
clusA::> metrocluster node show
DR
----- ------- ------------------ -------------- --------- --------------------
   clusA clusA-01           ready to configure
          -                          -
    clusA-02           ready to configure
          -                          -
    clusA-03           ready to configure
          -                          -
    clusA-04           ready to configure
          -                          -
4 entries were displayed.
clusA::> metrocluster node show -partners
Node (HA Partner) DR Partner (DR Auxiliary)
----------------------------- -----------------------------
Cluster:                       clusA -
    clusA-01 (-) - (-)
    clusA-02 (-) - (-)
```
The following example shows the output of the command when some DR groups in the MetroCluster configuration are not yet configured:

```
clusA::> metrocluster node show
DR Group Cluster Node Configuration DR State Mirroring Mode
----- ------- ------------------ -------------- -------- --------------------
- clusA clusA-03 ready to configure
- clusA-04 ready to configure
1 clusA clusA-01 configured enabled normal
  clusA-02 configured enabled normal
clusB clusB-01 configured enabled normal
clusB-02 configured enabled normal
6 entries were displayed.

**metrocluster operation commands**

Display MetroCluster operation status

**metrocluster operation show**

Display details of the last MetroCluster operation

**Availability:** This command is available to cluster administrators at the `admin` privilege level.

**Description**
The `metrocluster operation show` command displays information about the most recent MetroCluster operation run on the local cluster.

This command will display information about all MetroCluster commands except for the commands in the `metrocluster check` directory. This command will not display any information after MetroCluster has been completely unconfigured using the `metrocluster unconfigure` command.

**Examples**
The following example shows the output of `metrocluster operation show` after running a `metrocluster configure` command was successful:

```
clusA::> metrocluster operation show
  Operation: configure
    State: successful
  Start time: 2/15/2013 18:22:46
  End time: 2/15/2013 18:25:18
  Errors: -
```

**metrocluster operation history commands**

The history directory

**metrocluster operation history show**

Display details of all MetroCluster operations

**Availability:** This command is available to cluster administrators at the `admin` privilege level.

**Description**
The `metrocluster operation history show` command displays information about all the MetroCluster operations run on the local cluster.
This command will display information about all MetroCluster commands except for the commands in the `metrocluster check` directory. This command will not display any information after MetroCluster has been completely unconfigured using the `metrocluster unconfigure` command.

### Parameters

{ 
  [-fields <fieldname>, ...]
  
  If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

  | [-instance ] |
  
  If you specify the `-instance` parameter, the command displays detailed information about all fields.

  [-operation-uuid <UUID>] - Identifier for the Operation
  
  This is the UUID of the operation. If this parameter is specified, only the operation with this UUID is displayed.

  [-cluster <Cluster name>] - Cluster Where the Command Was Run
  
  This is the name of the cluster where the command was run. If this parameter is specified, only the operations that were run in this cluster are displayed.

  [-node-name <Node name>] - Node Where the Command Was run
  
  This is the name of the node where the command was run. If this parameter is specified, only the operations that were run on this node are displayed.

  [-operation <MetroCluster Operation Name>] - Name of the Operation
  
  This is the name of the operation. If this parameter is specified, only the operations with this name are displayed.

  [-start-time <MM/DD/YYYY HH:MM:SS>] - Start Time
  
  This is the time the operation started execution. If this parameter is specified, only the operations that were started at this time are displayed.

  [-state <MetroCluster Operation state>] - State of the Operation
  
  This is the state of the operation. If this parameter is specified, only the operations that are in this state are displayed.

  [-end-time <MM/DD/YYYY HH:MM:SS>] - End Time
  
  This is the time the operation completed. If this parameter is specified, only the operations that completed at this time are displayed.

  [-error-list <text>, ...] - Error List For the Operation
  
  This is the list of errors that were encountered during an operation's execution. If this parameter is specified, only the operations that have the matching errors are displayed.

  [-job-id <integer>] - Identifier for the Job
  
  This is the job id for the operation. If this parameter is specified, only the operation that has the matching job id displayed.

### Examples

The following example shows the output of `metrocluster operation history show` after some MetroCluster operations have been performed:

```
clusA::> metrocluster operation history show
Operation        State          Start time       End time
---------------- -------------- ---------------- ------------------
```

** metrocluster vserver resync  
Resynchronize Vserver with it's partner Vserver  

**Availability:** This command is available to cluster administrators at the admin privilege level.  

**Description**  
The metrocluster vserver resync command resynchronizes the Vserver with it's partner Vserver  

**Parameters**  
-`-cluster <Cluster name>` - Cluster Name  
  Name of the cluster where the Vserver belongs  

-`-vserver <vserver>` - Vserver  
  Name of the Vserver to be resynchronized  

**Examples**  
```bash  
cluster::> metrocluster vserver resync -cluster clus1 -vserver vs1  
```

**Related references**  
metrocluster vserver show on page 255

** metrocluster vserver show  
Display MetroCluster Vserver relationships  

**Availability:** This command is available to cluster administrators at the admin privilege level.  

**Description**  
The metrocluster vserver show command displays configuration information for all pairs of Vservers in MetroCluster.  

**Parameters**  
-`[ [-fields <fieldname>, ...]`  
The command output includes the specified field or fields  

|`[-creation-time ] (privilege: advanced)`  
Shows the last configuration modification time on the Vserver  

|`[-instance ]}  
If you specify the `-instance` parameter, the command displays detailed information about all fields.  

-`[-cluster <Cluster name>]` - Cluster Name  
  Name of the cluster where the Vserver belongs  

-`[-vserver <vserver>]` - Vserver  
  Name of the Vserver  

-`[-partner-vserver <vserver>]` - Partner Vserver  
  Name of the partner Vserver  

metrocluster vserver commands 255
Configuration states include:

- **healthy**
- **unhealthy**
- **degraded** indicates that Vservers are not in sync
- **syncing** indicates that the Vserver configuration is being synchronized
- **replication-paused** indicates that the configuration replication was manually paused
- **pending-setup** indicates that partner Vserver creation is pending

**Corrective Action**

Corrective action which can be followed to successfully create the partner Vserver

**Creation Time on the source**

Last configuration modification time on the Vserver

**Is out of sync**

Indicates that the Vserver configuration replication is not in sync

**Configuration Resume Time**

Displays the resume time of the Vserver configuration replication

### Examples

The following example shows the output of the command when partner Vservers are created

```
clusA::> metrocluster vserver show
Cluster: clusA
  Vserver       Partner        Configuration
  -----------    -----------    -----------
  clusA         clusB          healthy
  vs1           vs1-mc         healthy

Cluster: clusB
  Vserver       Partner        Configuration
  -----------    -----------    -----------
  clusB         clusA          healthy

3 entries were displayed.
```

The following example shows the output of the command when the partner Vserver creation is pending

```
clusA::> metrocluster vserver show
Cluster: clusA
  Vserver       Partner        Configuration
  -----------    -----------    -----------
  clusA         clusB          healthy
  vs1           -              pending-setup

Corrective Action: Create Ipspace ips1 on the partner cluster.

2 entries were displayed.
```

## Network Commands

Manage physical and virtual network connections

The `network` commands enable you to manage the network interfaces in a cluster.

### network ping

Ping

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

**Description**
The `network ping` command displays whether a remote address is reachable and responsive, the (if specified) number of transmitted and received packets, and their round-trip time. The command requires a source node or logical interface from where the ping will be run, and a destination IP address. You can specify the source node by name, or a logical interface and its Vserver.

**Parameters**

- `-node <nodename>` - *Node*
  Use this parameter to send the ping from the node you specify.

- `-lif <lif-name>` - *Logical Interface*
  Use this parameter to send the ping from the logical interface you specify.

- `-vserver <vserver>` - *Vserver*
  Use this parameter to send the ping from the Vserver where the intended logical interface resides. The default value is the system Vserver for cluster administrators.

- `[-use-source-port {true|false}]` - *Use Source Port of Logical Interface* (privilege: advanced)
  This parameter is only applicable when the `-lif` parameter is specified. When set to true, the ping packet will be sent out via the port which is currently hosting the IP address of the logical interface. Otherwise, the ping packet will be sent out via a port based on the routing table.

- `-destination <Remote InetAddress>` - *Destination*
  Use this parameter to specify the remote internet address destination of the ping.

- `[-show-detail | -s [true]]` - *Show Detail Output*
  Use this parameter to display detailed output about the ping.

- `[-record-route | -R [true]]` - *Record Route*
  Use this parameter to display the route followed by the ping. You should set this option to *false* for pinging to succeed.

- `[-verbose | -v [true]]` - *Show All ICMP Packets*
  Use this parameter to display all ICMP packets.

- `[-packet-size <integer>]` - *Packet Size*
  Use this parameter to specify the number of data bytes to be sent in the ping packet. The default is 56 bytes, which is 64 ICMP data bytes total after 8 bytes of ICMP header data is added.
[-count <integer>] - Count
Use this parameter to specify the maximum number of ECHO_REQUESTS to be sent to the destination. The default is 20 requests. In the absence of the 'show-detail' option, ping reports that the destination is alive after receiving the first ECHO_REPLY response, independent of this value.

[-wait <integer>] - Packet Send Wait Time (secs)
Use this parameter to specify the number of seconds to wait between sending packets. The default is one second.

[-flood [true]] - Flood Ping (privilege: advanced)
Use this parameter to execute the command in flood mode. In flood mode, the command issues pings as fast as they are received, unless you specify a wait time.

[-disallow-fragmentation | -D [true]] - Disallow Packet Fragmentation
Use this parameter to prevent transport mechanisms from fragmenting ping packets in transit. Preventing fragmentation assures consistent packet size, making it easier to see transport bottlenecks.

[-wait-response <integer>] - Packet Response Wait Time (ms)
Use this parameter to specify the number of milliseconds to wait for each response packet. The default is 10000 milliseconds (10 seconds).

Examples
This example shows a ping from node xena to the destination server 10.98.16.164 with the server responding that it is up and running.

```
cluster1:/> network ping -node xena -destination 10.98.16.164
(network ping)
10.98.16.164 is alive
```

network ping6
Ping an IPv6 address

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The network ping6 command uses the ICMPv6 protocol's mandatory ICMP6_ECHO_REQUEST datagram to elicit an ICMP6_ECHO_REPLY from a host or gateway. ICMP6_ECHO_REQUEST datagrams ("pings") have an IPv6 header, and ICMPv6 header formatted as documented in RFC2463.

Parameters

{-node <nodename> - Node Name
Use this parameter to originate ping6 from the specified node.

|-lif <lif-name> - Logical Interface
Use this parameter to originate ping6 from the specified logical interface.

-vserver <vserver name> - Vserver Name
Use this parameter to originate ping6 from the specified Vserver. The default value is the system Vserver for cluster administrators.

-destination <Remote InetAddress> - Destination
Use this parameter to specify the IPv6 address of the destination node.
[ -buffer-size | -b <integer>] - Socket Buffer Size
Use this parameter to set the socket buffer size.

[ -count | -c <integer>] - Max Requests to Send/Receive
Use this parameter to specify the maximum number of requests and replies. The default value is 20.

[ -reverse-lookup | -H [true]] - Reverse-lookup of IPv6 addresses
Use this parameter to specify reverse-lookup of IPv6 addresses. Unless this parameter is specified, ping6 command does not attempt reverse lookup.

[ -interval | -i <integer>] - Wait between Packets (secs)
Use this parameter to specify the delay time between packets in seconds. The default value is 1 second. This parameter is incompatible with the flood parameter.

[ -preload | -l <integer>] - Send Packets as Fast as Possible (privilege: advanced)
Use this parameter if preload is required. If specified, ping6 sends that many packets as fast as possible before falling into its normal mode of behaviour.

[ -use-source-port (true|false)] - Use Source Port of Logical Interface (privilege: advanced)
This parameter is only applicable when the -lif parameter is specified. When set to true, the ping packet will be sent out via the port which is currently hosting the IP address of the logical interface. Otherwise, the ping packet will be sent out via a port based on the routing table.

[ -pattern | -p <text>] - Up to 16 'pad' Specified for Out Packet
Use this parameter to fill the -16 'pad' bytes in the sent packet. This is useful for diagnosing data dependent problems in a network. For example, -pattern ff causes the sent packet to be filled with all ones.

[ -packet-size <integer>] - Packet Size
Use this parameter to specify the number of data bytes to be sent. The default is 56, which translates to 64 ICMP data bytes when combined with the 8 bytes of ICMP header data.

[ -verbose | -v [true]] - Show All ICMP Packets
Use this parameter to get verbose output. Verbose output displays both source address and destination addresses. Received ICMP packets other than ECHO_RESPONSE are listed. This parameter can be used only in conjunction with the show-detail parameter.

[ -fqdn-query | -w [true]] - (DEPRECATED)-FQDN Query
Note: This parameter is deprecated and may be removed in a future version of Data ONTAP.
Use this parameter to generate ICMPv6 Node Information FQDN query, rather than echo-request.

[ -fqdn-query-03-draft | -W [true]] - (DEPRECATED)-FQDN Query but with 03 Draft
Note: This parameter is deprecated and may be removed in a future version of Data ONTAP.
Use this parameter to generate FQDN query with old packet format based on 03 draft. This option is available for backward compatibility.

[ -show-detail | -s [true]] - Show Detail Output
Use this parameter to display detailed output about the ping.

[ -flood | -f [true]] - Flood Ping (privilege: advanced)
Use this parameter to output packets as fast as they come back or one hundred times per second, whichever is more. For every ECHO_REQUEST sent a period "." is printed, while for every ECHO_REPLY received a backspace is printed. This provides a rapid display of how many packets are being dropped. This can be very hard on a network and should be used with caution.

Examples
This example shows a ping6 from node 'node1' to the destination server ipv6.google.com with the server responding that it is up and running.

network test-path

Test path performance between two nodes

**Availability:** This command is available to cluster administrators at the advanced privilege level.

**Description**

The `network test-path` command runs a performance test between two nodes. The command requires a source node, destination node, destination cluster, and application, or session type. All tests are run using intracluster or intercluster LIFs, depending on whether the test is between two nodes in the same cluster, or between nodes in peered clusters.

The test itself is different from most bandwidth test tools. It creates a "session" consisting of TCP connections between all possible paths between the nodes being tested. This is how internal Data ONTAP applications communicate between nodes. This means the test is using multiple paths, and thus the bandwidth reported might exceed the capacity of a single 10 Gb path.

**Parameters**

- `--source-node <nodename>|local` - Node Initiating Session
  
  Use this parameter to specify the node that initiates the test. Source-node parameter must be a member of the cluster in which the command is run.

- `--destination-cluster <cluster name>` - Cluster Containing Passive Node
  
  Use this parameter to specify the destination cluster; the local cluster, or a peered cluster.

- `--destination-node <text>` - Remote Node in Destination Cluster
  
  Use this parameter to specify the destination node in the destination cluster.

- `--session-type {AsyncMirrorLocal|AsyncMirrorRemote|RemoteDataTransfer}` - Type of Session to Test
  
  The session type parameter is used to mimic the application settings used. A session consists of multiple TCP connections.
  
  - AsyncMirrorLocal: settings used by SnapMirror between nodes in the same cluster
  - AsyncMirrorRemote: settings used by SnapMirror between nodes in different clusters
  - RemoteDataTransfer: settings used by Data ONTAP for remote data access between nodes in the same cluster

  The default session-type is AsyncMirrorRemote.

**Examples**

The following example runs a test between two nodes in the same cluster:

```
cluster1::*> network test-path --source-node node1 --destination-cluster cluster1 --destination-node node2
```

network test-link on page 353

network traceroute

Traceroute

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description

The network traceroute command performs a network probe from a node to a specified IP address. The command requires a source node or logical interface and a destination IP address. You can specify the source node by name, or specify a logical interface and its Vserver. The traceroute is performed between the source and destination.

Parameters

{-node <nodename> - Node
   Use this parameter to originate the traceroute from the node you specify.

|-lif <lif-name> - Logical Interface
   Use this parameter to originate the traceroute from the interface group you specify.

-vserver <vserver> - LIF Owner
   Use this parameter to originate the traceroute from the Vserver where the intended logical interface resides. The default value is the system Vserver for cluster administrators.

-destination <Remote InetAddress> - Destination
   Use this parameter to specify the remote internet address destination of the traceroute.

[-maxttl | -m <integer>] - Maximum Number of Hops
   Use this parameter to specify the maximum number of hops (time-to-live) setting used by outgoing probe packets. The default is 30 hops.

[-numeric | -n [true]] - Print Hop Numerically
   Use this parameter to print the hop addresses only numerically rather than symbolically and numerically.

[-port <integer>] - Base UDP Port Number
   Use this parameter to specify the base UDP port number used in probes. The default is port 33434.

[-packet-size <integer>] - Packet Size
   Use this parameter to specify the size of probe packets, in bytes.

[-nqueries | -q <integer>] - Number of Queries
   Use this parameter to specify the number of probes per hop. The default is 3 probes.

[-verbose | -v [true]] - Verbose Output
   Use this parameter to display all received ICMP packets, rather than just TIME_EXCEEEDED and UNREACHABLE packets.
network traceroute6

traceroute6

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The network traceroute6 command performs a network probe from a node to a specified IPv6 address. The command requires a source node or logical interface, Vserver from where traceroute6 will originate and a destination IPv6 address. traceroute6 is performed between the source and destination.

Parameters

{-node <nodename> - Node
  Use this parameter to originate traceroute6 from the node you specify. This parameter is available only to cluster administrators.

|-lif <lif-name>- Logical Interface
  Use this parameter to originate traceroute6 from the logical interface you specify.

-vserver <vserver name>- LIF Owner
  Use this parameter to originate traceroute6 from the Vserver you specify. The default value is the system Vserver for cluster administrators.

[-debug-mode | -d [true]] - Debug Mode
  Use this parameter to enable socket level debugging. The default value is false.

{[-icmp6 | -I [true]] - ICMP6 ECHO instead of UDP
  Use this parameter to specify the use of ICMP6 ECHO instead of UDP datagrams for the probes. The default value is false.

|[-udp | -U [true]]] - UDP
  Use this parameter to specify the use of UDP datagrams for the probes. The default value is true.

[-numeric | -n [true]] - Print Hops Numerically
  Use this parameter to print the hop addresses only numerically rather than symbolically and numerically. The default value is false.
[-verbose | -v [true]] - Verbose Output
Use this parameter to display all received ICMP packets, rather than just TIME_EXCEEDED and UNREACHABLE packets. The default value is false.

[-first-hop | -f <integer>] - Number of Hops to Skip in Trace
Use this parameter to specify the number of hops to skip in trace. The default value is 1.

[-gateway | -g <Remote InetAddress>] - Intermediate Gateway
Use this parameter to specify the intermediate gateway.

[-hop-limit | -m <integer>] - Maximum Number of Hops
Use this parameter to specify the maximum hoplimit, upto 255. The default value is 64 hops.

[-port | -p <integer>] - Base UDP Port Number
Use this parameter to specify the base UDP port number used in probes. The default value is port 33434.

[-nqueries | -q <integer>] - Number of Queries
Use this parameter to specify the number of probes per hop. The default value is 3 probes.

[-wait-time | -w <integer>] - Wait Between Packets (secs)
Use this parameter to specify the delay time between probes in seconds. The default value is 5 seconds.

-destination <Remote InetAddress> - Destination
Use this parameter to specify the remote IPv6 address destination of traceroute6.

[-packet-size <integer>] - Packet Size
Use this parameter to specify the size of probe packets, in bytes. The default value is 16 bytes for ICMP6 ECHO and 12 bytes for UDP datagrams.

Examples
The following example shows traceroute6 from node node1 to the destination fd20:8b1e:b255:4071:d255:1fcd:a8cd:b9e8.

```
cluster1::> network traceroute6 -node node1 -vserver vs1
        -destination 3ffe:b00:c18:1::10
traceroute6 to 3ffe:b00:c18:1::10 (3ffe:b00:c18:1::10)
          from 2001:0db8:0000:f101::2, 64 hops max, 12 byte packets
1  2001:0db8:0000:f101::1  4.249 ms  2.021 ms  0.864 ms
2  3ffe:2000:0:400::1  0.831 ms  0.579 ms
3  3ffe:2000:0:1::132  227.693 ms  227.596 ms  227.439 ms
4  3ffe:c00:8023:2b:2.229.0208 ms  228.267 ms  231.891 ms
5  3ffe:2e00:e::3  227.929 ms  228.696 ms  228.558 ms
6  3ffe:b00:c18:1::10  227.702 ms  227.806 ms  227.439 ms
```

network cloud commands
Manage cloud-based features
network cloud routing-table commands

Manage external routing tables

network cloud routing-table create

Create a new external routing table

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
The network cloud routing-table create command creates a new external routing table.

Parameters
- route-table-id <text> - Route Table ID
  This parameter is used to provide the name of the external routing table to be created.

Examples
The following example creates an external routing table "eni-123456":

```
cluster1::> network cloud routing-table create -route-table-id eni-123456
```

network cloud routing-table delete

Delete an existing external routing table

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
The network cloud routing-table delete deletes an existing external routing table.

Parameters
- route-table-id <text> - Route Table ID
  This parameter is used to provide the name of an existing external routing table to be deleted.

Examples
The following example deletes the external routing table "eni-123456":

```
cluster1::> network cloud routing-table delete -route-table-id eni-123456
```

network arp commands

The arp directory

network arp create

Create static ARP entry

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.
**Description**
The `network arp create` command creates a static ARP entry for a given Vserver. Statically created ARP entries will be stored permanently in the Vserver context and will be used by the network stack.

**Parameters**

-vserver <vserver name> - Vserver Name

Use this parameter to specify the name of the Vserver on which the ARP entry is created.

-remotehost <IP Address> - Remote IP Address

Use this parameter to specify the IP address to be added as an ARP entry.

-mac <MAC Address> - MAC Address

Use this parameter to specify the MAC address (Ethernet address) for the host specified with -remotehost. Specify the MAC address as six hex bytes separated by colons.

**Examples**
The following example creates a static ARP entry on Vserver vs1 for the remote host with the IP address 10.63.0.2 having MAC address 40:55:39:25:27:c1

```
cluster1::> network arp create -vserver vs1 -remotehost 10.63.0.2 -mac 40:55:39:25:27:c1
```

**network arp delete**
Delete static ARP entry

**Availability:** This command is available to `cluster` and `Vserver` administrators at the `admin` privilege level.

**Description**
The `network arp delete` command deletes static ARP entries from the Vserver and from the network stack.

**Parameters**

-vserver <vserver name> - Vserver Name

Use this parameter to specify the name of the Vserver from which the ARP entry is deleted.

-remotehost <IP Address> - Remote IP Address

Use this parameter to specify the IP address of the ARP entry being deleted.

**Examples**
The following example deletes the ARP entry for IP address 10.63.0.2 from the Vserver vs1.

```
cluster1::> network arp delete -vserver vs1 -remotehost 10.63.0.2
```

**network arp show**
Display static ARP entries

**Availability:** This command is available to `cluster` and `Vserver` administrators at the `admin` privilege level.

**Description**
The `network arp show` command displays static ARP entries present in a given Vserver. This command will not display dynamically learnt ARP entries in the network stack. Use the `network arp active-entry show` command to display dynamically learned ARP entries in the network stack.
Parameters

{[-fields <fieldname>,...]

Use this parameter to display only certain fields of the ARP table.

[[-instance]]

Use this parameter to display all the fields of the ARP table.

[-vserver <vserver name>] - Vserver Name

Use this parameter to display ARP entries that are specific to a given Vserver.

[-remotehost <IP Address>] - Remote IP Address

Use this parameter to display ARP entries for the specified IP address.

[-mac <MAC Address>] - MAC Address

Use this parameter to display ARP entry for the specified MAC address.

[-ipspace <IPspace>] - IPspace

Use this parameter to specify the IPspace associated with the Vserver.

Examples

The following example displays static ARP entries from the Vserver vs1.

```
cluster1::> network arp show -vserver vs1
Vserver     Remote Host       MAC Address
----------- ----------------- -----------------
vs1                10.238.0.2        40:55:39:25:27:c1
```

network arp active-entry show on page 267

network arp active-entry commands

Manage active ARP entries

network arp active-entry delete

Delete active ARP entry

Availability: This command is available to cluster administrators at the advanced privilege level.

Description

The network arp active-entry delete command deletes ARP entry from the network stack of node. Using this command, you can delete only dynamically learned ARP entries. To delete statically configured ARP entries use the network arp delete command.

Parameters

- `node {<nodename>|local}` - Node
  
  Use this parameter to specify the name of the node in which the ARP entry is deleted.

- `vserver <vserver>` - Vserver Name

  Use this parameter to specify the name of the Vserver in which the ARP entry is deleted.

- `subnet-group <IP Address/Mask>` - Subnet Group Name

  Use this parameter to specify the name of the routing group in which the ARP entry is deleted.
-remotehost <text> - Remote IP Address
  Use this parameter to specify the IP address to be deleted from the active ARP entries.

-port <text> - Port
  Use this parameter to specify the name of the Port to be deleted from the active ARP entries. This is an optional parameter. If Port is not specified then command will be applied to all the matching Ports

Examples
The following example deletes the ARP entry for IP address 169.254.42.9 from the Vserver vs1 and from the subnet group 169.254.0.0/16 and from port lo.

cluster1::*> network arp active-entry delete -vserver vs1 -subnet-group 169.254.0.0/16 -remotehost 169.254.42.9 -port lo

network arp delete on page 265

network arp active-entry show
Display active ARP entries

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
The network arp active-entry show command displays ARP entries present in the network stack of the node. The entries includes both dynamically learned ARP entries and user configured static ARP entries.

Parameters

\{ [-fields <fieldname>, ...] \}
  Use this parameter to display only certain fields of the active ARP table.

| [-instance ] |
  Use this parameter to display all the fields of the active ARP table.

[-node {<nodename>|local}] - Node
  Use this parameter to display active ARP entries that are specific to a given node.

[-vserver <vserver>] - Vserver Name
  Use this parameter to display active ARP entries that are specific to a given Vserver.

[-subnet-group <IP Address/Mask>] - Subnet Group Name
  Use this parameter to display active ARP entries that are specific to a given subnet group.

[-remotehost <text>] - Remote IP Address
  Use this parameter to display active ARP entries for the specified IP address

[-port <text>] - Port
  Use this parameter to display active ARP entries for the specified Port name

[-mac <text>] - MAC Address
  Use this parameter to display active ARP entry for the specified MAC address

[-ipspace <IPspace>] - IPspace
  Use this parameter to specify the IPspace associated with the Vserver
Examples
The following example displays active ARP entries from the Vserver vs1.

```
cluster1:~*> network arp active-entry show -vserver vs1
Node: node-01
Vserver: vs1
Subnet Group: 169.254.0.0/16
Remote IP Address  MAC Address       Port
----------------- ----------------- -------
169.254.106.95    0:55:39:27:d1:c1  lo
```

network connections commands
The connections directory

network connections active commands
The active directory

network connections active show
Show the active connections in this cluster

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The `network connections active show` command displays information about active network connections.

Note: The results of this command set are refreshed independently every 30 seconds and might not reflect the immediate state of the system.

Parameters

```
{ [-fields <fieldname>, ...]
    If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

[ [-print-ip-addresses ]
    Print IP addresses for remote hosts -- do not attempt to resolve the addresses to a hostname.

[ [-instance ]
    If you specify the -instance parameter, the command displays detailed information about all fields.

[ -node (<nodename> | local)] - Node
    Selects the connections that match this parameter value.

[ -cid <cid>] - Connection ID
    Selects the connections that match this parameter value.

[ -vserver <vserver>] - Vserver
    Selects the connections that match this parameter value.

[ -lif-name <lif-name>] - Logical Interface Name
    Selects the connections that match this parameter value.
```
[-local-address <IP Address>] - Local IP address
Selects the connections that match this parameter value.

[-local-port <integer>] - Local Port
Selects the connections that match this parameter value.

[-remote-ip <InetAddress>] - Remote IP Address
Selects the connections that match this parameter value.

[-remote-host <Remote IP>] - Remote Host
Selects the connections that match this parameter value.

[-remote-port <integer>] - Remote Port
Selects the connections that match this parameter value.

[-proto (UDP|TCP)] - Protocol
Selects the connections that match this parameter value. Possible values are tcp (TCP), udp (UDP), and NA (not applicable).

[-lifid <integer>] - Logical Interface ID
Selects the connections that match this parameter value.

[-service <protocol service>] - Protocol Service
Selects the connections that match this parameter value. Possible values include: nfs, iscsi, and loopback.

[-lru {yes|no}] - Least Recently Used
Selects the connections that match this parameter value.

[-blocks-lb {true|false}] - Connection Blocks Load Balance Migrate
Selects the logical interfaces that are blocked (true) or not blocked (false) from migrating due to an active client connection.

Examples
The following example displays information about active network connections for the node named node0:

```
cluster1::> network connections active show node -node0

Vserver Interface        Remote
Name    Name:Local Port  IP Address:Port   Protocol/Service
------- ---------------- ----------------- ----------------
node0   cluslif1:7070    192.0.2.253:48621 UDP/rclopcp
node0   cluslif1:7070    192.0.2.253:48622 UDP/rclopcp
node0   cluslif2:7070    192.0.2.250:48644 UDP/rclopcp
node0   cluslif1:7070    192.0.2.250:48646 UDP/rclopcp
node0   cluslif1:7070    192.0.2.248:48622 UDP/rclopcp
node0   cluslif2:7070    192.0.2.245:48621 UDP/rclopcp
node0   cluslif1:7070    192.0.2.245:48622 UDP/rclopcp
node0   cluslif1:7070    192.0.2.250:48646 UDP/rclopcp
node0   cluslif2:7070    192.0.2.250:48644 UDP/rclopcp
node0   cluslif2:7070    192.0.2.251:48644 UDP/rclopcp
node0   cluslif2:7070    192.0.2.251:48646 UDP/rclopcp
node0   cluslif1:7070    192.0.2.253:48621 UDP/rclopcp
node0   cluslif1:7070    192.0.2.253:48622 UDP/rclopcp

[...]
```

At privilege levels above “admin”, the command displays an extra column:

```
cluster1::*> network connections active show node -node0

Vserver Interface        Remote                             LB
Name    Name:Local Port  IP Address:Port   Protocol/Service Migrate
------- ---------------- ----------------- ---------------- -------
node0   cluslif1:7070    192.0.2.253:48621 UDP/rclopcp      false
node0   cluslif1:7070    192.0.2.253:48622 UDP/rclopcp      false
```

network connections commands
network connections active show-clients

Show a count of the active connections by client

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The network connections active show-clients command displays information about client connections, including the client's IP address and the number of client connections.

Note: The results of this command set are refreshed independently every 30 seconds and might not reflect the immediate state of the system.

Parameters

[-fields <fieldname>, ...]  
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

[-instance ]
If you specify the -instance parameter, the command displays detailed information about all fields.

[-node <nodename>|local] - Node
Use this parameter to display information only about the connections on the node you specify.

[-vserver <vserver>] - Vserver
This parameter is used by the system to break down the output per vserver.

[-remote-address <Remote IP>] - Remote IP Address
Use this parameter to display information only about the connections that use the remote IP address you specify.

[-count <integer>] - Client Count
Use this parameter to only clients with the number of active client connections you specify.

Examples
The following example displays information about active client connections:

```
cluster1::> network connections active show-clients
     Node  Vserver Name  Client IP Address  Count
    ------  -----------  -----------------  ------
 node0   vs1       192.0.2.253     1
          vs2       192.0.2.252     2
          vs3       192.0.2.251     5
 node1   vs1       192.0.2.250     1
          vs2       192.0.2.252     3
          vs2      customer.example.com     4
```
network connections active show-lifs

Show a count of the active connections by logical interface

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The network connections active show-lifs command displays the number of active connections on each logical interface, organized by node and Vserver.

Note: The results of this command set are refreshed independently every 30 seconds and might not reflect the immediate state of the system.

Parameters
[-fields <fieldname>,...]
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

[-instance]
If you specify the -instance parameter, the command displays detailed information about all fields.

[-node {<nodename>|local]} - Node
Use this parameter to display information only about the connections on the node you specify.

[-vserver <vserver>] - Vserver
Use this parameter to display information only about the connections that are using the node or Vserver you specify.

[-lif-name <lif-name>] - Logical Interface Name
Use this parameter to display information only about the connections that are using the logical interface you specify.

[-count <integer>] - Client Count
Use this parameter to display only logical interfaces with the number of active client connections you specify.

[-blocked-count <integer>] - (DEPRECATED)-Load Balancing Blocking Count
Note: This parameter has been deprecated and may be removed in a future version of Data ONTAP.
Use this parameter to display information only about data logical interfaces blocked from migrating and the connection that is blocking it.

Examples
The following example displays information about the servers and logical interfaces being used by all active connections:

<table>
<thead>
<tr>
<th>Node</th>
<th>Vserver Name</th>
<th>Interface Name</th>
<th>Count</th>
</tr>
</thead>
<tbody>
<tr>

network connections active show-protocols

Show a count of the active connections by protocol

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

**Description**

The `network connections active show-protocols` command displays the number of active connections per protocol, organized by node.

**Note:** The results of this command set are refreshed independently every 30 seconds and might not reflect the immediate state of the system.

**Parameters**

`[-fields <fieldname>, ...]`

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

`[-instance ]`

If you specify the `-instance` parameter, the command displays detailed information about all fields.

`[-node {<nodename>|local}] - Node`

Use this parameter to display information only about the connections on the node you specify.

`[-vserver <vserver>] - Vserver`

This parameter is used by the system to break down the output per vserver.

`[-proto {UDP|TCP}] - Protocol`

Use this parameter to display information only about the connections that use the network protocol you specify. Possible values include tcp (TCP), udp (UDP), and NA (not applicable).

`[-count <integer>] - Client Count`

Use this parameter to display only protocols with the number of active client connections you specify.
### Examples

The following example displays information about all network protocols being used by active connections:

```
cluster1::> network connections active show-protocols
Node   Vserver Name   Protocol   Count
-------  --------------  ---------  ------
node0
  vs1             UDP            19
  vs1             TCP            11
  vs2             UDP            17
node1
  vs1             UDP            14
  vs2             TCP            10
```

### network connections active show-services

Show a count of the active connections by service

**Availability:** This command is available to cluster and Vserver administrators at the admin privilege level.

**Description**

The `network connections active show-services` command displays the number of active connections by protocol service, organized by node.

**Note:** The results of this command set are refreshed independently every 30 seconds and might not reflect the immediate state of the system.

**Parameters**

```
[-fields <fieldname>, ...]
```

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

```
[-instance]
```

If you specify the `-instance` parameter, the command displays detailed information about all fields.

```
[-node {<nodename>|local}]
```

- **Node**
  
  Use this parameter to display information only about the connections on the node you specify.

```
[-vserver <vserver>]
```

- **Vserver**
  
  This parameter is used by the system to break down the output per vserver.

```
[-service <protocol service>]
```

- **Protocol Service**
  
  Use this parameter to display information only about the connections that use the protocol service you specify. Possible values include: nfs, iscsi, and loopback.

```
[-count <integer>]
```

- **Client Count**
  
  Use this parameter to display information only about protocol services with the number of active client connections you specify.

### Examples

The following example displays information about all protocol services being used by active connections:

```
cluster1::> network connections active show-services
Node   Vserver Name   Service   Count
-------  --------------  ---------  ------
node0
  vs1             mount           3
  vs1             nfs             14
  vs1             nlm_v4          4
  vs1             cifs_srv        3
```
network connections listening commands

The listening directory

network connections listening show

Show the listening connections in this cluster

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description

The network connections listening show command displays information about network connections that are in an open and listening state.

Parameters

`[-fields <fieldname>, ...]`

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

`[-instance]`

If you specify the `-instance` parameter, the command displays detailed information about all fields.

`[-node <nodename> | local]` - Node

Selects the listening connections that match this parameter value.

`[-mgmt-cid <integer>]` - Management Connection ID

Selects the listening connections that match this parameter value.

`[-vserver <vserver>]` - Vserver

Selects the listening connections that match this parameter value.

`[-cid <integer>]` - System Connection ID

Selects the listening connections that match this parameter value.

`[-lif-name <lif-name>]` - Logical Interface Name

Selects the listening connections that match this parameter value.

`[-local-address <IP Address>]` - Local IP Address

Selects the listening connections that match this parameter value.

`[-local-port <integer>]` - Local Port

Selects the listening connections that match this parameter value.

`[-remote-ip <InetAddress>]` - Remote IP Address

Selects the listening connections that match this parameter value.

`[-remote-host <Remote IP>]` - Remote Host

Selects the listening connections that match this parameter value.

`[-remote-port <integer>]` - Remote Port

Selects the listening connections that match this parameter value.
[-proto {UDP|TCP}] - Protocol

Selects the listening connections that match this parameter value. Possible values include tcp (TCP), udp (UDP), and NA (not applicable).

[-lifid <integer>] - Logical Interface ID

Selects the listening connections that match this parameter value.

[-service <protocol service>] - Protocol Service

Selects the listening connections that match this parameter value. Possible values include: nfs, iscsi, and loopback.

[-lru {yes|no}] - Least Recently Used

Selects the listening connections that match this parameter value.

### Examples

The following example displays information about all listening network connections:

```bash
cluster1::> network connections listening show
Vserver Name Interface Name:Local Port Protocol/Service
---------- -------------------------- -----------------
node0      cluslif1:7700            UDP/rclopcp
node0      cluslif2:7700            UDP/rclopcp
node1      cluslif1:7700            UDP/rclopcp
node1      cluslif2:7700            UDP/rclopcp
node2      cluslif1:7700            UDP/rclopcp
node2      cluslif2:7700            UDP/rclopcp
node3      cluslif1:7700            UDP/rclopcp
node3      cluslif2:7700            UDP/rclopcp
8 entries were displayed.
```

The following example displays detailed information about listening network connections for the node named node0:

```bash
cluster1::> network connections listening show -node node0
Node: node0
Management Connection Id: 0
System Connection Id: 0
Vserver: vs0
Logical Interface Name: datalif1
  Local IP address: 192.0.2.130
  Local Port: 111
  Remote IP address: 
  Remote Port: 0
  Protocol: UDP
Logical Interface Id: 1029
Protocol Service: port_map
least recently used: yes
Node: node0
Management Connection Id: 1
System Connection Id: 0
Server: vs0
Logical Interface Name: datalif2
  Local IP address: 192.0.2.131
  Local Port: 111
  Remote IP address: 
  Remote Port: 0
  Protocol: UDP
Logical Interface Id: 1030
Protocol Service: port_map
least recently used: yes
```

### network fcp commands

The fcp directory

Commands used for managing FCP target adapters.
network fcp adapter commands

The adapter directory

Commands used for managing FCP adapters.

network fcp adapter modify

Modify the fcp adapter settings

Availability: This command is available to cluster administrators at the admin privilege level.

Description
Modifies the FCP target adapter information.

The adapter argument is in the form Xy or Xy_z where X and z are integers and y is a letter. An example is 4a or 4a_1.

You cannot bring an adapter offline until all logical interfaces connected to that adapter are offline. Use the network interface modify command to take your logical interfaces offline.

The speed option sets the Fibre Channel link speed of an adapter. You can set adapters that support:

- 10Gb/s to 10 or auto
- 8Gb/s to 2, 4, 8 or auto
- 4Gb/s to 2, 4 or auto
- 2Gb/s to 2 or auto

By default, the link speed option is set to auto for auto negotiation. Setting the link speed to a specific value disables auto negotiation. Under certain conditions, a speed mismatch can prevent the adapter from coming online.

Note: The system reports the actual link speed with the "Data Link Rate (Gbit)" field in the output of network fcp adapter show -instance.

Parameters

-node {<nodename>|local} - Node
  Specifies the node of the target adapter.

-adapter <text> - Adapter
  Specifies the target adapter.

-status-admin {down|up} - Administrative Status
  Specifies the desired (administrative) status of the adapter. To view the actual operational status, run network fcp adapter show -fields status-oper.

-speed {1|2|4|8|10|16|32|auto} - Configured Speed
  Specifies the adapter configuration speed in Gigabytes.

Examples

cluster1::> network fcp adapter modify -node node1 -adapter 0d -speed 2

Related references

network fcp adapter show on page 277
network interface modify on page 287
network fcp adapter show

Display FCP adapters

Availability: This command is available to cluster administrators at the admin privilege level.

Description
Displays FCP target adapter information. You can also use this information to determine if adapters are active and online.
The adapter argument is in the form Xy or Xy_z where X and z are integers and y is a letter. An example is 4a or 4a_1.

Parameters

[-fields <fieldname>, ...]
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use -fields ? to display the fields to specify.

[-instance]
If you specify the -instance parameter, the command displays detailed information about all fields.

[-node {<nodename> | local}] - Node
The name for the node on which the adapter is present.

[-adapter <text>] - Adapter
The name of the adapter.

[-description <text>] - Description
A high level description of the adapter.

[-physical-protocol {fibre-channel | ethernet}] - Physical Protocol
The physical layer protocol for the adapter.

[-max-speed {1 | 2 | 4 | 8 | 10 | 16 | 32 | auto}] - Maximum Speed
The maximum possible speed for the adapter.

[-status-admin {down | up}] - Administrative Status
The administrative status of the adapter.

[-status-oper <text>] - Operational Status
The operational status of the adapter.

[-status-extended <text>] - Extended Status
An extended status contains more detailed information than an operational status.

[-portaddr <Hex Integer>] - Host Port Address
This address refers to the address assigned to the adapter by the fabric.

[-firmware-rev <text>] - Firmware Revision
The revision of the firmware that is running on the ASIC.

[-data-link-rate <integer>] - Data Link Rate (Gbit)
The established data link rate.

[-fabric-established {true | false}] - Fabric Established
True indicates that the adapter has logged into the SAN fabric and a connection is established.

[-fabric-name <text>] - Fabric Name
The WWN of the fabric to which the adapter is connected.

[-conn-established {loop | ptp}] - Connection Established
The type of connection established.
[-media-type \{loop|ptp|auto\}] - Mediatype
The setting for the connection.

[-speed \{1|2|4|8|10|16|32|auto\}] - Configured Speed
The speed at which the adapter is configured to run on. If the speed is negotiated, then the value is auto.

[-fc-wwnn <text>] - Adapter WWNN
The World Wide Node Name for the node.

[-fc-wwpn <text>] - Adapter WWPN
The World Wide Port Name for the adapter.

[-switch-port <text>] - Switch Port
The name of the fabric switch port connected to the adapter.

[-sfp-formfactor <text>] - Form Factor Of Transceiver
The form factor of the Transceiver.

[-sfp-vendor-name <text>] - Vendor Name Of Transceiver
The vendor name of the Transceiver.

[-sfp-part-number <text>] - Part Number Of Transceiver
The part number of the Transceiver.

[-sfp-rev <text>] - Revision Of Transceiver
The revision number of the Transceiver.

[-sfp-serial-number <text>] - Serial Number Of Transceiver
The serial number of the Transceiver.

[-sfp-fc-speed-capabilities <text>] - FC Capabilities Of Transceiver
The speed capabilities of the Transceiver.

[-sfp-vendor-oui <text>] - Vendor OUI Of Transceiver
The OUI of the vendor of the Transceiver.

[-sfp-wavelength <integer>] - Wavelength In Nanometers
The wavelength in nano-meters of the Transceiver.

[-sfp-date-code <text>] - Date Code Of Transceiver
The date code present in the Transceiver.

[-is-sfp-optical-transceiver-valid \{true|false\}] - Validity Of Transceiver
Identifies if the SFP optical transceiver on the specified adapter is valid or not.

[-sfp-connector <text>] - Connector Used
The type of connector used in the Transceiver.

[-sfp-encoding <text>] - Encoding Used
The physical encoding type used by the Transceiver.

[-is-sfp-diagnostics-internally-calibrated \{true|false\}] - Is Internally Calibrated
Identifies if the Transceiver diagnostics have been internally calibrated.

[-sfp-rx-power <text>] - Received Optical Power
The received optical power of the Transceiver.

[-is-sfp-rx-power-in-range \{true|false\}] - Is Received Power In Range
Indicates if the Transceiver receive power for the specified adapter is in range.
**-sfp-tx-power <text>** - SPF Transmitted Optical Power

The transmitted optical power of the Transceiver.

**-is-sfp-tx-power-in-range {true|false}** - Is Xmit Power In Range

Indicates if the transmit power of the Transceiver is in range.

### Examples

```
cluster1::> fcp adapter show
Connection | Host
------------ ------- ----------- ------------
Node        | Adapter Established Port Address
------------ ------- ----------- ------------
sti6280-021 | 0a ptp 30012c
```

The example above displays information regarding FCP adapters within cluster1.

```
cluster1::> fcp adapter show -instance -node sti6280-021 -adapter 0a

Node: sti6280-021
Adapter: 0a
Description: Fibre Channel Target Adapter 0a (QLogic 2532 (2562), rev. 2, 8G)
Physical Protocol: fibre-channel
Maximum Speed: 8
Administrative Status: up
Operational Status: online
Extended Status: ADAPTER UP
Host Port Address: 30012c
Firmware Revision: 5.8.0
Data Link Rate (Gbit): 4
Fabric Established: true
Fabric Name: 20:14:54:7f:ee:54:b9:01
Connection Established: ptp
Mediatype: ptp
Configured Speed: auto
Adapter WWNN: 50:0a:09:80:8f:7f:8b:1c
Adapter WWPN: 50:0a:09:81:8f:7f:8b:1c
Switch Port: RTP-AG01-410B51:1/41
Form Factor Of Transceiver: SFP
Vendor Name Of Transceiver: OPNEXT, INC
Part Number Of Transceiver: TRS2000EN-SC01
Revision Of Transceiver: 0000
Serial Number Of Transceiver: T10H64793
FC Capabilities Of Transceiver: 10 (Gbit/sec)
Vendor OUI Of Transceiver: 0:11:64
Wavelength In Nanometers: 850
Date Code Of Transceiver: 10:08:17
Validity Of Transceiver: true
Connector Used: LC
Encoding Used: 64B66B
Is Internally Calibrated: true
Received Optical Power: 441.3 (uWatts)
Received Power In Range: true
SPF Transmitted Optical Power: 600.4 (uWatts)
Is Xmit Power In Range: true
```

### network device-discovery commands

The device-discovery directory

**network device-discovery show**

Display device discovery information

**Availability:** This command is available to `cluster` administrators at the `admin` privilege level.
Description
The network device-discovery show command displays information about discovered devices. This information may be useful
in determining the network topology or investigating connectivity issues. By default, the command displays the following
information:

- Local interface
- Discovered device
- Discovered interface
- Discovered platform

Parameters

[-fields <fieldname>, ...]
Include the specified field or fields in the command output. Use ‘-fields ?’ to display the valid fields.

[-instance ]
Use this parameter to display detailed information about all fields.

[-node <nodename>] - Node
Displays the discovery ports that match the node name.

[-protocol {cdp|lldp}] - Protocol
Displays the devices that are discovered by the given protocol.

[-port <text>] - Port
Displays the discovery ports that match the physical network port. For example, e0a will display devices
discovered on port e0a.

[-discovered-device <text>] - Discovered Device
Displays the discovered devices that match the discovered device name.

[-interface <text>] - Discovered Device Interface
Displays the discovered devices that match this interface port name. The format is dependent on the reporting
device. For example: FastEthernet0/12

[-device-ip <IP Address>, ...] - Discovered Device IP Addresses
Displays the discovered devices that match the IP address(es). At present, only IPv4 addresses are included. It
is recommended to use wildcards around the desired value.

[-platform <text>] - Discovered Device Platform
Displays the discovery ports that contain the platform of discovered devices. For example: N5K-C5010P-BF

[-version <text>] - Discovered Device Version
Displays the discovery ports that contain the version of discovered devices.

[-hold-time-remaining <integer>] - Discovered Device's Remaining Hold Time
Displays the discovered devices that match the remaining packet hold time in seconds. If an advertisement
from the device isn't received before this time reaches zero, the entry will expire and be removed from the list.
For example, "<120" will display discovered devices which will expire within the next 120 seconds.

[-capabilities {router|trans-bridge|source-route-bridge|switch|host|igmp|repeater|phone}, ...] - Discovered Device Capabilities
Displays the discovered devices that match the capability or capabilities. Possible values:

- "router" - Router
- "trans-bridge" - Trans Bridge
- "source-route-bridge" - Source Route Bridge
- "switch" - Switch
- "host" - Host
- "igmp" - IGMP
- "repeater" - Repeater
- "phone" - Phone

### Examples

```
cluster1::> network device-discovery show

```

### network interface commands

Manage logical interfaces

#### network interface create

Create a logical interface

**Availability:** This command is available to `cluster` administrators at the `admin` privilege level.

**Description**

The `network interface create` command creates a logical interface (LIF).

**Note:** A logical interface is an IP address associated with a physical network port. For logical interfaces using NAS data protocols, the interface can fail over or be migrated to a different physical port in the event of component failures, thereby continuing to provide network access despite the component failure. Logical interfaces using SAN data protocols do not support migration or failover.

**Note:** On some cloud platforms, this operation might perform changes to the external route tables.

**Parameters**

```
-vserver <vserver> - Vserver Name
```

Use this parameter to specify the Vserver on which the LIF is created.
-**lif** <**lif-name**> - Logical Interface Name

Use this parameter to specify the name of the LIF that is created. For iSCSI and FC LIFs, the name cannot be more than 254 characters.

-**role** {cluster|data|node-mgmt|intercluster|cluster-mgmt} - Role

Use this parameter to specify the role of the LIF. LIFs can have one of five roles:

- Cluster LIFs, which provide communication among the nodes in a cluster
- Intercluster LIFs, which provide communication among peered clusters
- Data LIFs, which provide data access to NAS and SAN clients
- Node-management LIFs, which provide access to cluster management functionality
- Cluster-management LIFs, which provide access to cluster management functionality

LIFs with the cluster-management role behave as LIFs with the node-management role except that cluster-management LIFs can failover between nodes.

-**data-protocol** {nfs|cifs|iscsi|fcp|fcache|none}, ... - Data Protocol

Use this parameter to specify the list of data protocols that can be configured on the LIF. The supported protocols are NFS, CIFS, FlexCache, iSCSI, and FCP. NFS, CIFS, and FlexCache are available by default when you create a LIF. If you specify "none", the LIF does not support any data protocols. Also, none, iscsi, or fcp cannot be combined with any other protocols.

**Note:** The data-protocol field must be specified when the LIF is created and cannot be modified later.

-**home-node** <nodename> - Home Node

Use this parameter to specify the LIF’s home node. The home node is the node to which the LIF returns when the `network interface revert` command is run on the LIF.

-**home-port** {<netport>|<ifgrp>} - Home Port

Use this parameter to specify the LIF’s home port or interface group. The home port is the port or interface group to which the LIF returns when the `network interface revert` command is run on the LIF.

-**address** <IP Address> - Network Address

Use this parameter to specify the LIF’s IP address.

**Note:** A cluster LIF cannot be on the same subnet as a management or data LIF.

{ -**netmask** <IP Address> - Netmask

Use this parameter to specify the LIF’s netmask.

| -**netmask-length** <integer> - Bits in the Netmask

Use this parameter to specify the length (in bits) of the LIF’s netmask.

{ -**auto** {true|false} - IPv4 Link Local

Use this parameter to specify whether IPv4 link local addressing is enabled for this LIF.

| [ [-**subnet-name** <subnet name>]] - Subnet Name

Use this parameter to allocate the interface address from a subnet. If needed, a default route will be created for this subnet.

[-**status-admin** {up|down}] - Administrative Status

Use this parameter to specify whether the initial administrative status of the LIF is up or down. The default setting is up. The administrative status can differ from the operational status For example, if you specify the status as up but a network problem prevents the interface from functioning, the operational status remains as down.
[-failover-policy {system-defined|local-only|sfo-partner-only|disabled|broadcast-domain-wide}] - Failover Policy

Use this parameter to specify the failover policy for the LIF.

- system-defined - The system determines appropriate failover targets for the LIF. The default behavior is that failover targets are chosen from the LIF’s current hosting node and also from one other non-partner node when possible.
- local-only - The LIF fails over to a port on the local or home node of the LIF.
- sfo-partner-only - The LIF fails over to port on the home node or SFO partner only.
- broadcast-domain-wide - The LIF fails over to a port in the same broadcast domain as the home port.
- disabled - Failover is disabled for the LIF.

The failover policy for cluster logical interfaces is local-only and cannot be changed. The default failover policy for data logical interfaces is system-defined. This value can be changed.

**Note:** Logical interfaces for SAN protocols do not support failover. Thus, such interfaces will always show this parameter as disabled.

[-firewall-policy <policy>] - Firewall Policy

Use this parameter to specify the firewall policy for the LIF. A LIF can use a default firewall policy that corresponds to its role (management, cluster, intercluster, or data) or a custom firewall policy created by an administrator. View and modify existing firewall policies using the `system services firewall policy show` and `system services firewall policy modify` commands, respectively.

[-auto-revert {true|false}] - Auto Revert

Use this parameter to specify whether a data LIF is automatically reverted to its home node under certain circumstances. These circumstances include startup, when the status of the management database changes to either master or secondary, or when the network connection is made. The default setting is `false`. If you set the value of this parameter to `true`, load balancing migration capability of the data LIF is disabled (the `allow-lb-migrate` parameter is set to `false`).

**Note:** Logical interfaces for SAN traffic do not support auto-revert. Thus, this parameter is always `false` on such interfaces.

[-dns-zone {<zone-name>|none}] - Fully Qualified DNS Zone Name

Use this parameter to specify a unique, fully qualified domain name of a DNS zone to which this data LIF is added. You can associate a data LIF with a single DNS zone. All data LIFs included in a zone must be on the same Vserver. If a LIF is not added to a DNS zone the data LIF is created with the value `none`.

[-listen-for-dns-query {true|false}] - DNS Query Listen Enable

Use this parameter to specify if the LIF has to listen for DNS queries. The default value for this parameter is true.

[-allow-lb-migrate {true|false}] - (DEPRECATED)-Load Balancing Migrate Allowed (privilege: advanced)

**Note:** This parameter has been deprecated and may be removed in a future version of Data ONTAP.

Use this parameter to specify whether load balancing migration is activated for this data LIF. The default value of this parameter is `false`. If you set the value of this parameter to `true`, automatic revert capability for this data LIF is disabled (the `auto-revert` parameter is set to `false`). Also, data LIFs that migrate as a result of load balancing adhere to network interface failover rules.

**Note:** During times when a LIF is hosting active NFSv4, CIFS, or NRV connections, load balancing based LIF migrations between nodes will be temporarily disabled.
[-lb-weight {load|0..100}] - Load Balanced Weight (privilege: advanced)

Use this parameter to specify a load balancing weight for a data LIF. A valid numeric load balancing weight is any integer between 0 and 100. When you specify the same load balancing weight for all data LIFs in a DNS zone, client requests are uniformly distributed, similar to round-robin DNS. A data LIF with a low load balancing weight is made available for client requests less frequently than one that has a high load balancing weight. "load" is the default value of this parameter. If set to "load", node utilization statistics are used to dynamically assign the load balancing weight.

[-failover-group <failover-group>] - Failover Group Name

Use this parameter to specify the name of the failover group to associate with the LIF. Manage failover groups by using the network interface failover-groups command. Each broadcast domain has a default failover group which is created by the system automatically and has the same name as the broadcast domain. The failover group associated with the broadcast domain includes all ports in the broadcast domain. A logical interface's failover group is set to the failover group of the home port's broadcast domain by default, but this value can be modified.

Note: Logical interfaces for SAN protocols do not support failover. Thus, this parameter cannot be specified for such interfaces.

[-comment <text>] - Comment

Use this parameter to specify the comment to associate with the LIF.

[-force-subnet-association [true]] - Force the LIF's Subnet Association

This command will fail if the IP address falls within the address range of a named subnet. Set this to true to acquire the address from the named subnet and assign the subnet to the LIF.

[-is-dns-update-enabled [true|false]] - Is Dynamic DNS Update Enabled?

If this parameter is set to true, then dynamic DNS update is sent to the DNS server for the particular LIF entry if dynamic DNS updates are enabled for the corresponding Vserver. This field is set to true by default for both IPv4 and IPv6 LIFs. DNS Update is not supported on LIFs not configured with either the NFS or CIFS protocol.

Examples

The following example creates an IPv4 LIF named datalif1 and an IPv6 LIF named datalif2 on a Vserver named vs0. Their home node is node0 and home port is e0c. The failover policy broadcast-domain-wide is assigned to both LIFs. The firewall policy is data and the LIFs are automatically reverted to their home node at startup and under other circumstances. The datalif1 has the IP address 192.0.2.130 and netmask 255.255.255.128, and datalif2 has the IP address 3ffe:1::aaaa and netmask length of 64.

```
cluster1::> network interface create -vserver vs0 -lif datalif1 -role data -home-node node0 -home-port e0c -address 192.0.2.130 -netmask 255.255.255.128 -failover-policy broadcast-domain-wide -firewall-policy data -auto-revert true
cluster1::> network interface create -vserver vs0 -lif datalif2 -role data -home-node node0 -home-port e0c -address 3ffe:1::aaaa -netmask-length 64 -failover-policy broadcast-domain-wide -firewall-policy data -auto-revert true
```

network interface delete

Delete a logical interface

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The network interface delete command deletes a logical interface from a Vserver.

**Note:** If you are using SAN protocols and the LIF you want to delete is in a port set, you must remove the LIF from the port set before you can delete the LIF. To determine if a LIF is in a port set, use the `lun portset show` command. To remove the LIF from the port set, use the `lun portset remove` command.

**Note:** On some cloud platforms, this operation might perform changes to the external route tables.

Parameters
- `-vserver <vserver>` - Vserver Name
  Use this parameter to specify the Vserver on which the logical interface to be deleted is located.
- `-lif <lif-name>` - Logical Interface Name
  Use this parameter to specify the logical interface to delete.

Examples
The following example deletes a logical interface named cluslif3 that is located on a Vserver named vs0.

```
cluster1::> network interface delete -vserver vs0 -lif cluslif3
```

- `lun portset remove` on page 207

network interface migrate

Migrate a logical interface to a different port

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The network interface migrate command migrates a logical interface to a port or interface group on the node you specify.

**Note:** Manual migration of a logical interface can take up to 15 seconds to complete. Also, when you migrate a cluster logical interface, you must do so from the local node. Logical interface migration is a best-effort command, and can only be completed if the destination node and port are operational

**Note:** Logical interfaces for SAN protocols do not support migration. Attempts to do so will result in an error.

**Note:** On some cloud platforms, this operation might perform changes to the external route tables.

Parameters
- `-vserver <vserver>` - Vserver Name
  Use this parameter to specify the Vserver that owns the logical interface that is to be migrated.
-lif <lif-name> - Logical Interface Name
Use this parameter to specify the logical interface that is to be migrated.

[source-node <nodename>] - (DEPRECATED)-Source Node
Note: This parameter is deprecated and may be removed in a future release of Data ONTAP.
Use this parameter to specify the node from which the logical interface is to be migrated.

-destination-node <nodename> - Destination Node
Use this parameter to specify the node to which the logical interface is to be migrated.

-destination-port (<netport>|<ifgrp>) - Destination Port
Use this parameter to specify the port or interface group to which the logical interface is to be migrated.

-force [true] - Force Migrate Data LIF Flag (privilege: advanced)
Use this parameter to force the migration operation.

Examples
The following example migrates a logical interface named datalif1 on a Vserver named vs0 to port e0c on a node named node2:

```
cluster1::> network interface migrate -vserver vs0 -lif datalif1 -source-node vs0 -dest-node node2
```

network interface migrate-all
Migrate all data logical interfaces away from the specified node

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The network interface migrate-all command migrates all data logical interfaces from the node you specify.

Note: Manual migration of a logical interface can take up to 15 seconds to complete. Logical interface migration is a best-effort command and can only be completed if the destination node and port are operational. Logical interface migration requires that the logical interface be pre-configured with valid failover rules to facilitate failover to a remote node.

Note: Logical interfaces for SAN protocols do not support migration. Attempts to do so will result in an error.

Note: On some cloud platforms, this operation might perform changes to the external route tables.

Parameters
-node <nodename> - Node
Use this parameter to specify the node from which all logical interfaces are migrated. Each data logical interface is migrated to another node in the cluster, assuming that the logical interface is configured with failover rules that specify an operational node and port.

-port (<netport>|<ifgrp>) - Port
Use this parameter to specify the port from which all logical interfaces are migrated. This option cannot be used with asynchronous migrations. If this parameter is not specified, then logical interfaces will be migrated away from all ports on the specified node.

Examples
The following example migrates all data logical interfaces from the current (local) node.
network interface modify

Modify a logical interface

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The network interface modify command modifies attributes of a logical interface (LIF).

Note: You cannot modify some properties of an iSCSI or FCP LIF, such as -home-node or -home-port, if the LIF is in a port set. To modify these properties, first remove the LIF from the port set. To determine if a LIF is in a port set, use the lun portset show command. To remove the LIF from the port set, use the lun portset remove command.

Note: On some cloud platforms, this operation might perform changes to the external route tables.

Parameters
-vserver <vserver> - Vserver Name
Use this parameter to specify the Vserver on which the LIF to be modified is located.

-lif <lif-name> - Logical Interface Name
Use this parameter to specify the name of the LIF that is to be modified

[-home-node <nodename>] - Home Node
Use this parameter to modify the LIF's home node. The home node is the node to which the LIF returns when the network interface revert command is run on that LIF.

[-home-port {<netport>|<ifgrp>}] - Home Port
Use this parameter to modify the LIF's home port. The home port is the port or interface group to which the LIF returns when the network interface revert command is run on that LIF.

    Note: If you change this parameter for a cluster or management LIF, you must reboot the storage system to force the change to take effect.

[-address <IP Address>] - Network Address
Use this parameter to modify the LIF's IP address.

    Note: A cluster LIF cannot be on the same subnet as a data or management LIF.

{ [-netmask <IP Address>] - Netmask
Use this parameter to modify the LIF's netmask.

| [-netmask-length <integer>] - Bits in the Netmask
Use this parameter to modify the length (in bits) of the LIF's netmask.

[-subnet-name <subnet name>] - Subnet Name
Use this parameter to allocate the interface address from a subnet. Modifying this parameter will cause a new IP address to be allocated and assigned to the interface.

[-status-admin {up|down}] - Administrative Status
Use this parameter to modify the administrative status of the LIF. The administrative status can differ from the operational status. For example, if you specify the status as up but a network problem prevents the interface from functioning, the operational status remains as down.
[-failover-policy {system-defined|local-only|sfo-partner-only|disabled|broadcast-domain-wide}] - Failover Policy
Use this parameter to modify the failover policy for the LIF.

- system-defined - The system determines appropriate failover targets for the LIF. The default behavior is that failover targets are chosen from the LIF's current hosting node and also from one other non-partner node when possible.
- local-only - The LIF fails over to a port on the local or home node of the LIF.
- sfo-partner-only - The LIF fails over to a port on the home node or SFO partner only.
- broadcast-domain-wide - The LIF fails over to a port in the same broadcast domain as the home port.
- disabled - Failover is disabled for the LIF.

**Note:** The failover policy for cluster logical interfaces is local-only and cannot be changed. The default failover policy for data logical interfaces is system-defined. This value can be changed.

**Note:** Logical interfaces for SAN protocols do not support failover. Thus, such interfaces always show this parameter as disabled.

[-firewall-policy <policy>] - Firewall Policy
Use this parameter to set the firewall policy for the LIF. A LIF can use a default firewall policy that corresponds to its role (management, cluster, or data) or a custom firewall policy created by an administrator. When using a custom policy, the interface will fallback on its role's default policy for unspecified services.

View existing firewall policies with the "system services firewall policy show" command. Modify existing firewall policies with the "system services firewall policy modify" command.

[-auto-revert {true|false}] - Auto Revert
Use this parameter to modify whether a data LIF is reverted automatically to its home node under certain circumstances. These circumstances would include startup, when the status of the management database changes to either master or secondary, and when the network connection is made. The default setting is false. If you set the value of this parameter to true, the load balancing migration capability of the data LIF is disabled (the -allow-lb-migrate parameter is set to false).

**Note:** Logical interfaces for SAN traffic do not support auto-revert. Thus, this parameter is always false on such interfaces.

[-dns-zone {<zone-name>|none}] - Fully Qualified DNS Zone Name
Use this parameter to modify the unique, fully qualified domain name of the DNS zone to which this data LIF belongs. You can associate a data LIF with a single DNS zone. All data LIFs included in a zone must be on the same Vserver. If you do not specify a value for this parameter, the data LIF is created with the value none.

[-listen-for-dns-query {true|false}] - DNS Query Listen Enable
Use this parameter to specify if the LIF has to listen for DNS queries. The default value for this parameter is true.

[-allow-lb-migrate {true|false}] - (DEPRECATED)-Load Balancing Migrate Allowed (privilege: advanced)

**Note:** This parameter has been deprecated and may be removed in a future version of Data ONTAP.
Use this parameter to modify whether or not load balancing migration is enabled for this data LIF. The default value of this parameter is false. If you set the value of this parameter to true, the automatic revert capability of the data LIF is disabled (the -auto-revert parameter is set to false). Also, data LIFs that migrate as a result of load balancing adhere to network interface failover rules.

**Note:** During times when a LIF is hosting active NFSv4, CIFS, or NRV connections, load balancing based LIF migrations between nodes will be temporarily disabled.
- `lb-weight {load|0..100}` - Load Balanced Weight (privilege: advanced)
  Use this parameter to modify the load balancing weight of the data LIF. A valid load balancing weight is any integer between 1 and 100. If you specify the same load balancing weight for all data LIFs in a DNS zone, client requests are uniformly distributed, similar to round-robin DNS. A data LIF with a low load balancing weight is made available for client requests less frequently than one that has a high load balancing weight.

- `failover-group <failover-group>` - Failover Group Name
  Use this parameter to modify the name of the failover group to associate with the network interface. Manage failover groups using the `network interface failover-groups` command. Each broadcast domain has a default failover group which is created by the system automatically and has the same name as the broadcast domain. The failover group associated with the broadcast domain includes all ports in the broadcast domain. A logical interface's failover group is set to the failover group of the home port's broadcast domain by default, but this value can be modified.

  **Note:** Logical interfaces for SAN protocols do not support failover. Thus, this parameter cannot be specified for such interfaces.

- `comment <text>` - Comment
  Use this parameter to modify the comment associated with the LIF.

- `force-subnet-association [true]` - Force the LIF's Subnet Association
  This command will fail if the IP address falls within the address range of a named subnet. Set this to true to acquire the address from the named subnet and assign the subnet to the LIF.

- `is-dns-update-enabled {true|false}` - Is Dynamic DNS Update Enabled?
  If this parameter is set to true, then dynamic DNS update is sent to the DNS server for the particular LIF entry if dynamic DNS updates are enabled for the corresponding Vserver. This field is set to true by default for both IPv4 and IPv6 LIFs. DNS Update is not supported on LIFs not configured with either the NFS or CIFS protocol.

### Examples

The following example modifies a LIF named datalif1 on a logical server named vs0. The LIF's netmask is modified to 255.255.255.128.

```
cluster1:/> network interface modify -vserver vs0 -lif datalif1 -netmask 255.255.255.128
```

### network interface rename

Rename a logical interface

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**

Use the `network interface rename` command to change the name of an existing logical interface.
Parameters
- `vserver <vserver>` - Vserver Name
  Use this parameter to specify the Vserver on which the logical interface to rename is located.

- `lif <lif-name>` - Logical Interface Name
  Use this parameter to specify the name of the logical interface to rename.

- `newname <text>` - LIF
  Use this parameter to specify the new name of the logical interface. For iSCSI and FC LIFs, the name cannot be more than 254 characters.

Examples
The following example renames a cluster logical interface named cluslif1 to cluslif4 on a Vserver named vs0.

```
cluster1::> network interface rename -vserver vs0 -lif cluslif1 -newname cluslif4
```

network interface revert
Revert a logical interface to its home port

**Availability:** This command is available to cluster administrators at the `admin` privilege level.

**Description**
The `network interface revert` command reverts a logical interface that is not currently on its home port to its home port, assuming that the home node and port are both operational. A logical interface's home port is specified when the logical interface is created. Determine a logical interface's home port by using the `network interface show` command.

**Note:** When you revert a cluster logical interface, you must do so from the local node.

**Note:** On some cloud platforms, this operation might perform changes to the external route tables.

Parameters
- `vserver <vserver>` - Vserver Name
  Use this parameter to specify the Vserver on which the logical interface to be reverted is located.

- `lif <lif-name>` - Logical Interface Name
  Use this parameter to specify the logical interface that is to be reverted.

  **Note:** Logical interfaces for SAN protocols are always home. Thus, this command has no effect on such interfaces. The same applies to logical interfaces for NAS protocols that are already home.

Examples
The following example returns any logical interfaces that are not currently on their home ports to their home ports.

```
cluster1::> network interface revert -vserver * -lif *
```

network interface show

Display logical interfaces

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The network interface show command displays information about logical interfaces.

Running the command with the -failover parameter displays information relevant to logical interface failover rules.

Running the command with the -by-ipspace parameter displays information relevant to logical interfaces on a specific IPspace.

See the examples for more information.

You can specify additional parameters to display only information that matches those parameters. For example, to display information only about logical interfaces whose operational status is down, run the command with the -status-oper down parameter.

Parameters

\[-fields <fieldname>,...\]
If you specify the -fields <fieldname>,... parameter, the command displays only the fields that you specify.

\[-by-ipspace\]
Use this parameter to display logical-interfaces sorted by IPspace and Vserver.

\[-dns-zones\]
Use this parameter to display logical-interfaces and whether the interface is associated with a Domain Name System (DNS) load balancing zone.

\[-failover\]
Use this parameter to display logical-interface failover information.

\[-instance\]}
Use this parameter to display all the fields for the specified logical-interfaces.

\[-vserver <vserver>\] - Vserver Name
Use this parameter to display information only about logical interfaces on the Vserver you specify.
Use this parameter plus the -lif parameter to display detailed information only about the logical interface you specify.

\[-lif <lif-name>\] - Logical Interface Name
Use this parameter to display information only about logical interfaces that match the name you specify.
Use this parameter with the -vserver parameter to display detailed information only about the logical interface you specify.

\[-role \{cluster|data|node-mgmt|intercluster|cluster-mgmt\}\] - Role
Use this parameter to display information only about logical interfaces that are associated with network ports that have the role you specify.

\[-data-protocol \{nfs|cifs|iscsi|fcp|fcache|none\},...\] - Data Protocol
Use this parameter to display information only about logical interfaces that have the enabled data protocols you specify.

\[-home-node <nodename>\] - Home Node
Use this parameter to display information only about logical interfaces that have the home node you specify.
[home-port {<netport>|<ifgrp>}]- Home Port
Use this parameter to display information only about logical interfaces that have the home port or interface group you specify.

curr-node <nodename> - Current Node
Use this parameter to display information only about logical interfaces that are currently located on the node you specify.

curr-port {<netport>|<ifgrp>}- Current Port
Use this parameter to display information only about logical interfaces that are currently located on the port or interface group you specify.

status-oper {up|down} - Operational Status
Use this parameter to display information only about logical interfaces that have the operational status you specify.

status-extended <text> - Extended Status
Use this parameter to display information only about logical interfaces that match the extended status that you specify. This applies only to FCP logical interfaces.

numeric-id <integer> - Numeric ID (privilege: advanced)
Use this parameter to display information only about logical interfaces with the numeric ID (or range of IDs) you specify. The numeric ID is an integer that identifies the logical interface in the cluster.

is-home {true|false} - Is Home
Use this parameter to display information only about logical interfaces that are (true) or are not (false) currently located on their home node and port.

address <IP Address> - Network Address
Use this parameter to display information only about logical interfaces that match the IP address or address range you specify.

netmask <IP Address> - Netmask
Use this parameter to display information only about logical interfaces that have the netmask you specify.

netmask-length <integer> - Bits in the Netmask
Use this parameter to display information only about logical interfaces with a netmask that has the number of bits you specify.

subnet-name <subnet name> - Subnet Name
Use this parameter to display the logical interfaces that matches the subnet name.

status-admin {up|down} - Administrative Status
Use this parameter to display information only about logical interfaces that have the administrative status you specify.

failover-policy {system-defined|local-only|sfo-partner-only|disabled|broadcast-domain-wide} - Failover Policy
Use this parameter to display information only about logical interfaces that use the failover policy you specify.

firewall-policy <policy> - Firewall Policy
Use this parameter to display information only about logical interfaces that use the firewall policies you specify.

auto-revert {true|false} - Auto Revert
Use this parameter to display information only about logical interfaces that have auto-revert setting you specify.
Sticky (true|false) - Sticky Flag (privilege: advanced)
Use this parameter to display information only about logical interfaces that are "sticky". A sticky logical interface is one that has been manually migrated to another node and is not subject to auto-revert settings. A sticky logical interface remains at the migrated location until it is manually reverted or until it fails over to another node.

DNS Zone (<zone-name>|none) - Fully Qualified DNS Zone Name
Use this parameter to display information only about logical interfaces in the specified DNS zone.

Listen for DNS Query (true|false) - DNS Query Listen Enable
Use this parameter to display information only about logical interfaces that have the DNS query listen value you specify.

Allow LB Migrate (true|false) - (DEPRECATED)-Load Balancing Migrate Allowed (privilege: advanced)
Note: This parameter has been deprecated and may be removed in a future version of Data ONTAP.
Use this parameter to display information only about logical interfaces for which load balancing migration is activated (true) or not activated (false).

Load Weight (load|0..100) - Load Balanced Weight (privilege: advanced)
Use this parameter to display information only about logical interfaces that have the load balancing weight you specify.

Failover Group <failover-group> - Failover Group Name
Use this parameter to display information only about logical interfaces that are in the failover group you specify. Logical interfaces in the same failover group are capable of failing over to the same set of ports.

WWPN <text> - FCP WWPN
Use this parameter to display information only about logical interfaces that have the Fibre Channel Protocol port identifier (World Wide Port Name) you specify.

Address Family (ipv4|ipv6|ipv6z) - Address family
Use this parameter to view the address family that is in use on the interface. Only IPv4 and IPv6 non-zoned addresses can be configured. Configuration of IPv6z addresses is not allowed.

Comment <text> - Comment
Use this parameter to display information only about logical interfaces that have the comment you specify.

IPSantspace <IPspace> - IPspace of LIF
Use this parameter to display information only about logical interfaces on the IPspace you specify.

Is DNS Update Enabled (true|false) - Is Dynamic DNS Update Enabled?
Use this parameter to display information only about logical interfaces that have (true) or do not have (false) dynamic DNS updates enabled for them.

Examples
The following example displays general information about all logical interfaces.

```
cluster1::> network interface show
Logical    Status     Network            Current       Current Is
Interface  Admin/Oper Address/Mask       Node          Port    Home
----------- ---------- ------------------ ------------- ------- ----
cluster1
cluster_mgmt up/up      192.0.2.1/192 node0 e0M   true
node0_mgmt1 up/up      192.0.2.2/192 node0 e0M   true
node1_mgmt1 up/up      192.0.2.3/192 node1 e0M   true
Cluster
node0_clus1 up/up      192.0.2.66/192 node0 e0a   true
node0_clus2 up/up      192.0.2.66/192 node0 e0a   true
```

```

**network interface start-cluster-check**

Start the cluster check function

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

**Description**

The `network interface start-cluster-check` command initiates an accessibility check from every logical interface to every aggregate. Automatic checks run periodically, but this command manually initiates a check immediately.

This command produces no direct output. Any errors encountered during the check are reported in the event log. See the `event log show` command for more information.

**Examples**

This example shows an execution of this command, with all parameters and output.

```
cluster1::> network interface start-cluster-check
```

*event log show* on page 100

network interface capacity commands

The capacity directory

network interface capacity show

Display the number of IP data LIFs capable of being configured on the cluster.

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**
The `network interface capacity show` command displays the number of IP LIFs of role *data* supported on the cluster, as well as the number of IP LIFs of role *data* currently configured on the cluster.

**Note:** The number of IP LIFs of role *data* that are supported on a node depends on the hardware platform and the Cluster's Data ONTAP version. If one or more nodes in the cluster cannot support additional LIFs, then none of the nodes in the cluster can support additional LIFs.

**Examples**
The following displays the IP data LIF capacity.

```
cluster1:/> network interface capacity show
IP Data LIF      IP Data LIF
Supported Limit            Count
-----------------  ---------------
1024              256
```

network interface capacity details commands

The details directory

network interface capacity details show

Display details about the IP data LIFs capable of being configured on each node.

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

**Description**
The `network interface capacity details show` command displays the number of IP LIFs of role *data* that can be configured on each node, the number of IP data LIFs of role *data* that are supported on each node, and the number of IP data LIFs of role *data* that are configured to be homed on each node.

**Note:** The number of IP LIFs of role *data* that are supported on a node depends on the hardware platform and the Cluster's Data ONTAP version. If one or more nodes in the cluster cannot support additional LIFs, then none of the nodes in the cluster can support additional LIFs.

**Parameters**

```
[-fields <fieldname>, ...]
```

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.
If you specify the `-instance` parameter, the command displays detailed information about all fields.

```
[-instance]
```

Use this parameter to specify the node for which to obtain data LIF capacity.

```
[-node {<nodename> | local}] - Node Name
```

This parameter specifies the number of IP LIFs of role data that can be configured on the node at the currently running Data ONTAP version. To view the version of a node, use the `cluster image show` command.

```
[-capacity-for-node <integer>] - Number of IP data LIFs that can be configured on the node
```

This parameter specifies the number of IP LIFs of role data that are supported on the node at the current effective cluster version (ECV). To view the version of a node, use the `cluster image show` command.

```
[-limit-for-node <integer>] - Number of IP data LIFs that are supported on the node
```

This parameter specifies the number of IP LIFs of role data currently configured to be homed on the node. To view LIFs homed on this node, use the `network interface show -home-node` command.

```
[-count-for-node <integer>] - Number of IP data LIFs that are assigned to the node
```

Examples

The following displays the IP data LIF capacity.

```
cluster1::> network interface capacity details show
 IP Data LIF   IP Data LIF   IP Data LIF
Node   Capacity   Supported Limit   Count
 node1  512         512              128
 node2  512         512              128
```

network interface check commands

The check directory

network interface check failover commands

The failover directory

network interface check failover show

Discover if any LIFs might become inaccessible during a node outage, due to over-provisioning

Availability: This command is available to `cluster` administrators at the `admin` privilege level.

Description

This command identifies logical interfaces (LIFs) at risk of becoming inaccessible if their hosting nodes were to experience an outage. The source-nodes parameter is the only required input.

The tuple `<destination-nodes, vserv-name, lif-name>` is sufficient to uniquely identify a record in the returned listing. All fields other than source-nodes can be filtered on in the usual fashion. There are some examples of this filtering below.
Parameters

\{[-fields <fieldname>, ...]
If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

\{[-instance ]\}
If you specify the `-instance` parameter, the command displays detailed information about all fields.

[-destination-nodes <nodename>, ...] - Set Of Nodes Over Capacity
Use this parameter to display the nodes an at-risk LIF or LIFs could fail over to.

[-vserver-name <vserver>] - Vserver Name
Use this parameter to display only LIFs on the Vserver you specify.

[-lif-name <lif-name>] - LIF Name
Use this parameter to display at-risk information only about the LIF or LIFs whose name you specify.

-[source-nodes <nodename>, ...] - Nodes Going Down
List of nodes to test. At-risk LIFs currently hosted on these nodes will be identified. The list should contain no more than half the nodes in the cluster.

[-over-amount <integer>] - Amount Capacity Exceeded
Use this parameter to select only at-risk LIFs associated with a set of destination nodes whose amount over capacity matches the number you specify.

Note that the number of LIFs considered to be at risk may be higher than the actual amount over capacity a given set of nodes is. Once a given set of nodes is determined to be potentially over capacity, all LIFs whose set of failover target nodes is an exact match are marked as at risk. The amount over capacity is an upper bound on the number LIFs which could become unhosted if LIFs were to fail over in a random order, each to a target randomly selected from that LIF's configured failover targets.

[-failover-group <failover-group>] - Failover Group Name
Use this parameter to display information only about at-risk LIFs whose failover-group you specify.

[-failover-policy \{system-defined|local-only|sfo-partner-only|disabled|broadcast-domain-wide\}] - Failover Policy
Use this parameter to display information only about at-risk LIFs whose failover-policy you specify.

Examples

The following example shows all the at-risk LIFs for a specific two-node outage in a six-node cluster.

```
cluster1::> network interface check failover show -source-nodes node1,node5
Destination Nodes: node2, node3, node4, node6
Amount Over Capacity: 2
  Vserver   Logical Interface   Failover Group   Failover Policy
  -----------   ---------------   ----------------   ---------------------
  vs0         data1             Default          broadcast-domain-wide
  data2       Default          broadcast-domain-wide
  data3       Default          broadcast-domain-wide
  vs1         data1             Custom_Name      broadcast-domain-wide
  Destination Nodes: node2
  Amount Over Capacity: 1
  Vserver   Logical Interface   Failover Group   Failover Policy
  -----------   ---------------   ----------------   ---------------------
  vs0         data6             Default          sfo-partner-only
  vs1         data7             Default          sfo-partner-only
```

The following example shows the same two-node outage scenario, but now with some filtering applied to the results.

```
cluster1::> network interface check failover show -source-nodes node1,node5 -over-amount 1
Destination Nodes: node2
Amount Over Capacity: 1
  Vserver   Logical Interface   Failover Group   Failover Policy
  -----------   ---------------   ----------------   ---------------------
  vs0         data6             Default          sfo-partner-only
  vs1         data7             Default          sfo-partner-only
```
network interface dns-lb-stats commands

The dns-lb-stats directory

network interface dns-lb-stats show

Show the DNS load-balancer stats for this node

Availability: This command is available to cluster and Vserver administrators at the advanced privilege level.

Description
The network interface dns-lb-stats show command displays the statistics for DNS load-balancing lookups for the zones belonging to the specified Vserver. These statistics represent the data for the Vserver on the local node. The following counts can be seen in the statistics output:

• success-count : Number of successful lookups.
• authoritative-count : Number of authoritative answers sent.
• nonauthoritative-count : Number of non authoritative answers sent.
• rr-set-missing-count : Number of times the RR set was missing.
• domain-missing-count : Number of times the domain was not be found.
• failure-count : Number of failed lookups.
• dropped-count : Number of lookups dropped.

Parameters
{ [-fields <fieldname>, ...]
    If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.
}[ [-instance ]
    If you specify the -instance parameter, the command displays detailed information about all fields.
[ -vserver <vserver> ] - Vserver
    Use this parameter to display DNS load-balancer statistics only for the specified Vservers.
[ -zone <text> ] - DNS Zone
    Use this parameter to display DNS load-balancer statistics only for the specified DNS zones.
[ -success-count <integer> ] - Successful Lookup Count
    Use this parameter to display DNS load-balancer statistics only for the specified number of successful lookups.
[[-authoritative-count <integer>] - Authoritative Answer Count
   Use this parameter to display DNS load-balancer statistics only for the specified number of authoritative answers sent.

[[-nonauthoritative-count <integer>] - Non Authoritative Answer Count
   Use this parameter to display DNS load-balancer statistics only for the specified number of non-authoritative answers sent.

[[-rr-set-missing-count <integer>] - RR Set Missing Count
   Use this parameter to display DNS load-balancer statistics only for the specified number of times the RR set was missing.

[[-domain-missing-count <integer>] - Name Missing Count
   Use this parameter to display DNS load-balancer statistics only for the specified number of times the domain was not found.

[[-failure-count <integer>] - Failed Lookup Count
   Use this parameter to display DNS load-balancer statistics only for the specified number of failed lookups.

[[-dropped-count <integer>] - Dropped Count
   Use this parameter to display DNS load-balancer statistics only for the specified number of dropped lookups.

Examples
The following example displays stats for the zone "x.com".

<table>
<thead>
<tr>
<th>Vserver</th>
<th>DNS Zone</th>
<th>SUCCESS</th>
<th>AUTH</th>
<th>NOAUTH</th>
<th>NORR</th>
<th>NODOM</th>
<th>FAILED</th>
<th>DROP</th>
</tr>
</thead>
<tbody>
<tr>
<td>vs2</td>
<td>x.com</td>
<td>5</td>
<td>5</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

network interface lif-weights commands

The lif-weights directory

network interface lif-weights show

Show the load-balancer LIF weights

Availability: This command is available to cluster and Vserver administrators at the advanced privilege level.

Description
The network interface lif-weights show command displays the weights assigned to each LIF in a DNS load-balancing zone in a Vserver.

Parameters

[[-fields <fieldname>, ...]
   If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

[[-instance]]
   If you specify the -instance parameter, the command displays detailed information about all fields.

[-vserver <vserver>] - Vserver
   Use this parameter to display information only for the specified Vservers.
- DNS Zone
  Use this parameter to display information only for the specified DNS zones.

- Network Address
  Use this parameter to display information only for the specified IP addresses.

- Load Balancer Weight
  Use this parameter to display information only for the specified load balancer weights

Examples
The following example displays LIF weights for vserver "vs1".

```
cluster1::> network interface lif-weights show -vserver vs1
Vserver  DNS Zone            Address        Weight
---------  ------------------  ------------  -------
    vs1    a.com               4.4.4.4       12.4206
    vs1    x.com               1.1.1.1       12.4206
    vs1    x.com               10.72.46.236  12.4206
3 entries were displayed.
```

network interface failover-groups commands
Manage logical interface failover group configuration

network interface failover-groups add-targets
Add failover targets to a failover group

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The network interface failover-groups add-targets command enables you to add a list of failover targets such as network ports, interface groups, or VLANs to an existing logical interface failover group.

Parameters
- vserver <vserver> - Vserver Name
  Use this parameter to specify the name of the Vservers from which this failover group is accessible.

- failover-group <text> - Failover Group Name
  Use this parameter to specify the failover group that you want to extend.

- targets <<node>:<port>>, ... - Failover Targets
  Use this parameter to specify the failover targets such as network ports, interface groups, or VLANs you wish to add to the failover group.

Examples
This example shows the failover group "clyde" being extended to include additional failover targets.

```
cluster1::> network interface failover-group add-targets -vserver vs1 -failover-group clyde -
targets xenal:e0c, xenal:e0d-100, xena2:a0a
```
network interface failover-groups create

Create a new failover group

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The network interface failover-groups create command creates a grouping of failover targets for logical interfaces on one or more nodes. Use this command to add a new network port or interface group to an existing failover group.

Note: Interfaces for SAN protocols do not support failover. Such interfaces are not valid failover targets.

Parameters
-vserver <vserver> - Vserver Name
Use this parameter to specify the name of the Vservers from which this failover group is accessible.

-failover-group <text> - Failover Group Name
Use this parameter to specify the name of the logical interface failover group that you want to create.

-targets <<node>:<port>>, ... - Failover Targets
Use this parameter to specify the list of failover targets (network ports, interface groups, or VLANs on a node) belonging to this failover group.

Examples
The following example shows how to create a failover group named failover-group_2 containing ports e1e and e2e on node Xena.

```
cluster1::> network interface failover-groups create -vserver vs0 -failover-group failover-group_2 -targets xena:e1e,xena:e2e
```

network interface failover-groups delete

Delete a failover group

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The network interface failover-groups delete command deletes a logical interface failover group.

Parameters
-vserver <vserver> - Vserver Name
Use this parameter to specify the name of the Vservers from which this failover group is accessible.

-failover-group <text> - Failover Group Name
Use this parameter to specify the name of the logical interface failover group to be deleted.

Examples
The following example shows how to delete a failover group named failover-group_2.

```
cluster1::> network interface failover-groups delete -vserver vs1 -failover-group failover-group_2
```
network interface failover-groups modify

Modify a failover group

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The network interface failover-groups modify command enables you to modify the list of network ports, interface groups, or VLANs belonging to an existing logical interface failover group. The specified list will overwrite the existing list of network ports, interface groups, and VLANs currently belonging to the logical interface failover group.

Parameters
-vserver <vserver> - Vserver Name
Use this parameter to specify the name of the Vserver(s) from which this failover group is accessible.

-failover-group <text> - Failover Group Name
Use this parameter to specify the failover group that you want to modify.

[-targets <<node>:<port>>, ...] - Failover Targets
Use this parameter to specify the network ports, interface groups, or VLANs you wish to now belong to the failover group.

Examples
This example shows the failover group "clyde" being modified to now contain the specified network ports.

```
cluster1::> network interface failover-group modify -vserver vs1 -failover-group clyde -targets xena1:e0c, xena1:e0d-100, xena2:a0a
```

network interface failover-groups remove-targets

Remove failover targets from a failover group

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The network interface failover-groups remove-targets command enables you to specify a list of failover targets such as network ports, interface groups, or VLANs to be removed from an existing logical interface failover group.

Parameters
-vserver <vserver> - Vserver Name
Use this parameter to specify the name of the Vserver(s) from which this failover group is accessible.

-failover-group <text> - Failover Group Name
Use this parameter to specify the failover group that you want to remove failover targets from.

-targets <<node>:<port>>, ... - Failover Targets
Use this parameter to specify the failover targets such as network ports, interface groups, or VLANs you wish to remove from the failover group.

Examples
This example shows the failover targets xena1:e0c and xena1:e0d-100 being removed from the failover group "clyde".
network interface failover-groups rename

Rename a logical interface failover Group

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The network interface failover-groups rename command enables you to rename an existing logical interface failover group.

Parameters
-vserver <vserver> - Vserver Name
Use this parameter to specify the name of the Vservers from which this failover group is accessible.

-failover-group <text> - Failover Group Name
Use this parameter to specify the failover group that you want to rename.

-new-failover-group-name <text> - New name
Use this parameter to specify the new name of the failover group.

Examples
This example shows the failover group "clusterwide" being renamed "clyde".

cluster1::> network interface failover-group rename -failover -vserver vs1 -failover-group clusterwide -new-failover-group-name clyde

network interface failover-groups show

Display logical interface failover groups

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The network interface failover-groups show command displays information about logical interface failover groups.

Parameters
{-fields <fieldname>, ...}
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

{-instance}
If you specify the -instance parameter, the command displays detailed information about all fields.

-vserver <vserver> - Vserver Name
Use this parameter to display information only about the logical interface failover groups that have the target Vserver you specify.

-failover-group <text> - Failover Group Name
Use this parameter to display information only about the logical interface failover groups you specify.
[-targets <<node>:<port>>, ...] - Failover Targets

Use this parameter to display information only about the logical interface failover groups that have the failover target (physical port, interface group, or VLAN) you specify.

[-broadcast-domain <broadcast domain name>] - Broadcast Domain

Use this parameter to display information only about the logical interface failover groups that have the broadcast domain you specify.

Examples

The following example displays information about all logical interface failover groups on a two node cluster.

```
cluster1::> network interface failover-groups show

Failover Targets
Vserver          Group            Targets
---------------- ---------------- --------------------------------------------
Cluster          Cluster           node1:e1a, node1:e2a, node2:e1a, node2:e2a,
Cluster          Default           node1:e0M, node1:e0a, node1:e0b, node1:e0c,
                                 node1:e0d, node2:e0M, node2:e0a, node2:e0b,
                                 node2:e0c, node2:e0d
```

network ipspace commands

Manage IP Spaces

Network IPspace commands.

network ipspace create

Create a new IPspace

Availability: This command is available to cluster administrators at the admin privilege level.

Description

IPspaces are distinct IP address spaces in which Storage Virtual Machines (SVMs) reside. The "Cluster" IPspace and "Default" IPspace are created by default. You can create more custom IPspaces when you need your SVMs to have overlapping IP addresses, or you need more control over networking configurations for cluster peering. Please reference the "Network Management Guide" for the limit of how many custom IPspaces are supported on your system.

Parameters

-ipspace <IPspace> - IPspace name

The name of the IPspace to be created.

- The name must contain only the following characters: A-Z, a-z, 0-9, ".", "-" or "_".
- The first character of each label, delimited by ",", must be one of the following characters: A-Z or a-z.
- The last character of each label, delimited by ",", must be one of the following characters: A-Z, a-z or 0-9.
- The maximum supported length is 47 characters.
- The system reserves the following names: "all", "local" and "localhost".
The system provides the following IPspaces: "Cluster" and "Default".

Examples
The following example creates IPspace "ips1".

```
cluster1::> network ipspace create -name ips1
```

network ipspace delete
Delete an IPspace

Availability: This command is available to cluster administrators at the admin privilege level.

Description
Delete an IPspace that contains no ports or Vservers.

Parameters
- **-ipspace <IPspace>** - IPspace name
  
  The name of the IPspace to be deleted. If the IPspace is associated with one or more logical-interfaces, you must delete them before you can delete the IPspace.

Examples
The following example deletes the IPspace "ips1".

```
cluster1::> network ipspace delete -ipspace ips1
```

network ipspace rename
Rename an IPspace

Availability: This command is available to cluster administrators at the admin privilege level.

Description
Rename an IPspace.

Parameters
- **-ipspace <IPspace>** - IPspace name
  
  The name of the IPspace to be renamed.

- **-new-name <IPspace>** - New Name
  
  The new name for the IPspace.

  - The name must contain only the following characters: A-Z, a-z, 0-9, ",", ",", "_" or "_".
  
  - The first character of each label, delimited by ",", must be one of the following characters: A-Z or a-z.
  
  - The last character of each label, delimited by ",", must be one of the following characters: A-Z, a-z or 0-9.
  
  - The maximum supported length is 47 characters.

  - The system reserves the following names: "all", "cluster", "local" and "localhost".
Examples
The following example renames IPspace "ips1" to "ips2".

```
cluster1::> network ipspace rename -ipspace ips1 -new-name ips2
```

**network ipspace show**

Display IPspace information

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**
Display network IPspaces.

**Parameters**

```{-fields <fieldname>,...}
```

Specify the fields to be displayed for each IPspace.

| [-instance ]
```

Display all parameters of the IPspace objects.

```{-ipspace <IPspace> } - IPspace name
```

Display the names of the IPspaces.

```{-ports <node>:<port>,...} - Ports
```

The list of network ports assigned to each IPspace.

```{-broadcast-domains <broadcast domain name>,...} - Broadcast Domains
```

The list of broadcast domains that belong to the IPspace.

```{-vservers <vserver name>,...} - Vservers
```

The list of Vservers assigned to each IPspace.

---

**Examples**

The following example displays general information about IPspaces.

```
cluster1::> network ipspace show
IPspace             Vserver List                  Broadcast Domains
------------------- ----------------------------- ----------------------------
Cluster             Cluster                       -
Default             cluster1, vs1, vs2             br1, br2, br3
2 entries were displayed.
```

**network ndp commands**

Manage Neighbor Discovery Protocol

Network Discovery Protocol commands.
network ndp neighbor commands

Manage neighbor entries
Neighbor Discovery Protocol (NDP) neighbor commands.

network ndp neighbor create

Create a static NDP neighbor entry

Availability: This command is available to cluster and Vserver administrators at the advanced privilege level.

Description
The `network ndp neighbor create` command creates a static Neighbor Discovery Protocol (NDP) neighbor entry within a Vserver.

Parameters

- **-vserver `<vserver name>` - Vserver Name**
  Use this parameter to specify the Vserver on which the NDP neighbor is to be created.

- **-neighbor `<IP Address>` - Neighbor Address**
  Use this parameter to specify the neighbor's IPv6 address.

- **-mac-address `<MAC Address>` - MAC Address**
  Use this parameter to specify the neighbor's MAC address.

Examples
The following example creates a NDP neighbor entry within Vserver vs0.

```
cluster1::*> network ndp neighbor create -vserver vs0 -neighbor 20:20::20 -mac-address 10:10:10:0:0:1
```

network ndp neighbor delete

Delete a static NDP neighbor entry

Availability: This command is available to cluster and Vserver administrators at the advanced privilege level.

Description
The `network ndp neighbor delete` command deletes a static Neighbor Discovery Protocol (NDP) neighbor from a Vserver.

Parameters

- **-vserver `<vserver name>` - Vserver Name**
  Use this parameter to specify the Vserver on which the NDP neighbor is to be deleted.

- **-neighbor `<IP Address>` - Neighbor Address**
  Use this parameter to specify the neighbor's IPv6 address.

Examples
The following example deletes a NDP neighbor entry within Vserver vs0.

```
cluster1::*> network ndp neighbor delete -vserver vs0 -neighbor 20:20::20
```
network ndp neighbor show

Display static NDP neighbor entries

Availability: This command is available to cluster and Vserver administrators at the advanced privilege level.

Description
The network ndp neighbor show command displays a group of static Neighbor Discovery Protocol (NDP) neighbors within one or more Vservers. You can view static NDP neighbors within specified Vservers, neighbors with specified IPv6 address, and neighbors with specified MAC address.

Parameters

{-fields <fieldname>, ...}
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

{-instance}
If you specify the -instance parameter, the command displays detailed information about all fields.

[-vserver <vserver name>] - Vserver Name
Displays the static NDP neighbors that have the specified Vserver as their origin.

[-neighbor <IP Address>] - Neighbor Address
Displays the static NDP neighbors that have the specified IPv6 address.

[-mac-address <MAC Address>] - MAC Address
Displays the static NDP neighbors that have the specified MAC address.

Examples
The following example displays all of the static NDP neighbors configured on Vserver vs0.

```
cluster1::*> network ndp neighbor show -vserver vs0
  Vserver  Neighbor                 MAC Address
  --------- ------------------------ -------------------
  vs0      10:10::10                04:04:04:04:04:04
            20:20::20                01:01:01:01:01:01
2 entries were displayed.
```

network ndp neighbor active-entry commands

Manage neighbor active entries
NDP active neighbor commands.

network ndp neighbor active-entry delete

Delete active neighbor entry

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
The network ndp neighbor active-entry delete command deletes a Network Discovery Protocol (NDP) neighbor entry on the specified port from a given Vserver's subnet group.
Parameters

- **node \(<\text{nodename}\)> | local** - Node
  Use this parameter to specify the node on which the neighbor entry is to be deleted.

- **vserver \(<\text{vserver}\)>** - Vserver Name
  Use this parameter to specify the Vserver on which the neighbor entry is to be deleted.

- **subnet-group <IP Address/Mask>** - Subnet Group
  Use this parameter to specify the subnet group from which the neighbor entry is to be deleted.

- **neighbor <IP Address>** - Neighbor
  Use this parameter to specify the IPv6 address of the neighbor entry which is to be deleted.

- **port \(<\text{netport}\>|\ <\text{ifgrp}\)>** - Port
  Use this parameter to specify the port on which the neighbor entry is to be deleted.

Examples

The following example deletes a neighbor entry from Vserver ips1.

```
cluster1::*> network ndp neighbor active-entry delete -vserver ips1 -node local -subnet-group ::/0 -neighbor fe80:4::5:73ff:fea0:107 -port e0d
```

network ndp neighbor active-entry show

Display active neighbor entries

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

**Description**
The `network ndp neighbor active-entry show` command displays Network Discovery Protocol (NDP) neighbor cache entries on one or more nodes. You can view ndp neighbors within specified nodes and within specified Vservers.

**Parameters**

```
[-fields <fieldname>, ...]
```

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

```
[-verbose]
```

Displays the expire time, state, is-router, and probe count fields.

```
[-instance]
```

If you specify the `-instance` parameter, the command displays detailed information about all fields.

```
[-node \(<\text{nodename}\)> | local] - Node
```

Displays the NDP neighbors from the specified node.

```
[-vserver \(<\text{vserver}\)>] - Vserver Name
```

Displays the NDP neighbors from the specified Vserver.

```
[-subnet-group <IP Address/Mask>] - Subnet Group
```

Displays the NDP neighbors in the specified subnet group.

```
[-neighbor <IP Address>] - Neighbor
```

Displays the NDP neighbors that have the specified IPv6 address.

```
[-port \(<\text{netport}\>|\ <\text{ifgrp}\)>] - Port
```

Displays the NDP neighbors on the specified port.
[-mac-address \textless MAC Address\textgreater] - MAC Address
Displays the NDP neighbors have the specified MAC address.

[-expire-time \{\langle integer\rangle d|\langle integer\rangle h|\langle integer\rangle m|\langle integer\rangle s|\text{never}|\text{expired}\}] - Expire Time
Displays the NDP neighbors have the specified expire time.

[-state \{\text{nostate}|\text{incomplete}|\text{reachable}|\text{stale}|\text{delay}|\text{probe}|\text{unknown}\}] - State
Displays the NDP neighbors in the specified state.

[-is-router \{true|false\}] - Is Router
Displays the NDP neighbor which is a router.

[-probe-count \langle integer\rangle] - Probe Count
Displays the NDP neighbors with the specified probe count. Probe count is the number of times that this
neighbor's MAC address has been queried.

[-is-static \{true|false\}] - Is Static
Displays the NDP neighbors which are statically configured.

\textbf{Examples}

The following example displays NDP neighbors on Vserver ips1.

\begin{verbatim}
cluster1::*> network ndp neighbor active-entry show -vserver ips1
Node: node1
Vserver: ips1
Subnet Group: ::/0
Neighbor                      MAC Address          Port
------------------------------ -------------------- --------
fe80:4::5:73ff:fea0:107        00:05:73:a0:01:07    e0d
fe80:4::226:98ff:fe0c:b6c1     00:26:98:0c:b6:c1    e0d
3 entries were displayed.
\end{verbatim}

\textbf{network ndp default-router commands}

Manage default router entries
NDP default router commands.

\textbf{network ndp default-router delete-all}
Delete default routers on a given IPspace

\textbf{Availability:} This command is available to cluster administrators at the advanced privilege level.

\textbf{Description}
The \texttt{network ndp default-router delete-all} command deletes default router lists from the specified IPspace.

\textbf{Parameters}

-ipspace \langle IPspace\rangle - IPspace Name
Use this parameter to specify the IPspace where the default routers are to be deleted.

\textbf{Examples}
The following example deletes default routers from IPspace ips1.

\begin{verbatim}
cluster1::*> network ndp default-router delete-all -ipspace ips1
\end{verbatim}
network ndp default-router show

Display default routers

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
The network ndp default-router show command displays Neighbor Discovery Protocol (NDP) default routers learned on a specified port.

Parameters

([-fields <fieldname>, ...]
  If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

[-instance]]
  If you specify the -instance parameter, the command displays detailed information about all fields.

[-node {<nodename> | local}] - Node
  Displays the NDP default routers from the specified node.

[-ipspace <IPspace>] - IPspace name
  Displays the NDP default routers from the specified IPspace.

[-port {<netport> | <ifgrp>}] - Port
  Displays the NDP default routers from the specified port.

[-router-addr <IP Address>] - Router Address
  Displays the default routers that have the specified IPv6 addresses.

[-flag {none | managed-address-DHCPv6 | other-DHCPv6}] - Flag
  Displays the default routers that have the specified flag. The flag indicates whether addresses are available via DHCPv6 or other configuration information is available via DHCPv6.

[-expire-time {{<integer>d}|<integer>h|<integer>m|<integer>s} | never | expired}] - Expire Time
  Displays the default routers that have the specified expire time.

Examples
The following example displays NDP default routers on local port e0f.

```
cluster1:/> network ndp default-router show -port e0f -node local
```

Node: node1
IPspace: Default
<table>
<thead>
<tr>
<th>Port</th>
<th>Router Address</th>
<th>Flag</th>
<th>Expire Time</th>
</tr>
</thead>
<tbody>
<tr>
<td>e0f</td>
<td>fe80::5:73ff:fe0a:107</td>
<td>none</td>
<td>0d0h23m9s</td>
</tr>
</tbody>
</table>

network ndp prefix commands

Manage prefix entries

NDP prefix commands.
network ndp prefix delete-all

Delete IPv6 prefixes on a given IPspace

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
The network ndp prefix delete-all command deletes all prefixes learned from the specified IPspace.

Parameters
- `<ipspace>` - IPspace Name
  Use this parameter to specify the IPspace where the IPv6 prefixes are to be deleted.

Examples
The following example deletes all IPv6 prefixes within IPspace ips1.

```
cluster1::*> network ndp prefix delete-all -ipspace ips1
```

network ndp prefix show

Display IPv6 prefixes

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
The network ndp prefix show command displays IPv6 prefixes on one or more nodes.

Parameters
- `<fields <fieldname>, ...>`
  If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use -fields ? to display the fields to specify.

- `-verbose`
  Displays the valid-lifetime, preferred-lifetime, origin and advertising-router fields.

- `-instance []`
  If you specify the -instance parameter, the command displays detailed information about all fields.

- `<node [<nodename] | local>]` - Node
  Displays the IPv6 prefixes from the specified node.

- `<ipspace <IPspace>]` - IPspace name
  Displays the IPv6 prefixes from the specified IPspace.

- `<port [<netport] | <ifgrp>]>` - Port
  Displays the IPv6 prefixes on the specified port.

- `<prefix <IP Address/Mask>]` - Prefix
  Displays the IPv6 prefixes with the specified prefix value.

- `<flag [none|on-link|autonomous|on-link-autonomous]>` - Flag
  Displays the IPv6 prefixes with the specified flag. The flag indicates whether a prefix is on-link and whether it can be used in autonomous address configuration.
[-valid-lifetime {<unsigned integer>|infinity}] - Valid Lifetime
Displays the IPv6 prefixes having the specified valid lifetime in seconds.

[-preferred-lifetime {<unsigned integer>|infinity}] - Preferred Lifetime
Displays the IPv6 prefixes having the specified preferred lifetime in seconds.

[-expire-time {[<integer>d][<integer>h][<integer>m][<integer>s]|never|expired}] - Expire Time
Displays the IPv6 prefixes having the specified expire time.

[-origin {router-advertise|renumber-request|static|kernel|unknown}] - Origin of the Prefix
Displays the IPv6 prefixes with the specified origin.

[-advertising-router <IP Address>,...] - Router that Advertised the Prefix
Displays the IPv6 prefixes which are propagated by the specified router list.

Examples
The following example displays IPv6 prefixes on port e0f.

```
cluster1:*> network ndp prefix show -port e0f -node local
```

<table>
<thead>
<tr>
<th>Node: node1</th>
<th>IPspace: Default</th>

</tbody>
</table>

network options commands
The options directory

network options cluster-health-notifications commands
The cluster-health-notifications directory

network options cluster-health-notifications modify
cluster health notification options

Availability: This command is available to cluster administrators at the admin privilege level.

Description
This command enables or disables cluster health notifications on the specified node.

Parameters
- `-node <nodename>` - Node
  This parameter specifies the node for which the cluster health notification status will be modified.

[-enabled {true|false}] - Cluster Health Notifications Enabled
Setting this parameter to true enables cluster health notification. Setting it to false disables cluster health notification.

Examples
The following example modifies the cluster health notification status for a node:
network options cluster-health-notifications show

Display cluster health notification options

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The network options cluster-health-notifications show command displays whether the node's cluster health notifications are enabled.

Parameters

- `-fields <fieldname>, ...`
  If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

- `[-instance]`
  If you specify the `-instance` parameter, the command displays detailed information about all fields.

- `[-node <nodename>] - Node`
  This parameter specifies the node for which the cluster health notification status will be displayed.

- `-enabled {true|false}] - Cluster Health Notifications Enabled`
  Selects the entries that match this parameter value.

Examples
The following example displays the cluster health notification status for a node:

```bash
cluster1::> network options cluster-health-notifications show -node node1
Node: node1
Cluster Health Notifications Enabled: true
```

network options ipv6 commands

The ipv6 directory

network options ipv6 modify

Modify IPv6 options

Availability: This command is available to cluster administrators at the admin privilege level.

Description
This command sets the state of IPv6 options for the cluster.

Parameters

- `-enabled {true|false}] - IPv6 Enabled`
  Setting this parameter to `true` enables IPv6 for the cluster. IPv6 cannot be disabled once it is enabled for the cluster. Call technical support for guidance regarding disabling IPv6.
- `is-ra-processing-enabled {true|false}` - Router Advertisement (RA) Processing Enabled

  Setting this parameter to `true` enables cluster to process IPv6 router advertisements. Setting it to `false` disables router advertisement processing by the cluster.

  **Examples**

  The following example enables IPv6 for the cluster:
  
  cluster1::> network options ipv6 modify -enabled true

  The following example enables IPv6 Router Advertisement processing for the cluster:
  
  cluster1::> network options ipv6 modify -is-ra-processing-enabled true

  The following example disables IPv6 Router Advertisement processing for the cluster:
  
  cluster1::> network options ipv6 modify -is-ra-processing-enabled false

**network options ipv6 show**

Display IPv6 options

**Availability:** This command is available to `cluster` administrators at the `admin` privilege level.

**Description**

This command displays the current state of IPv6 options for the cluster.

**Examples**

cluster1::> network options ipv6 show

IPv6 Enabled: false
Router Advertisement (RA) Processing Enabled: false

**network options load-balancing commands**

The network options load-balancing directory

**network options load-balancing modify**

Modify load balancing algorithm

**Availability:** This command is available to `cluster` administrators at the `advanced` privilege level.

**Description**

This command sets the state of geometric mean algorithm for load balancing

**Parameters**

- `[-enable {true|false}]` - Geometric Mean Algorithm for load balancing

  Setting this parameter to `true` enables the geometric mean algorithm for load balancing. Setting it to `false` disables the geometric mean algorithm for the cluster.
network options load-balancing show

Display load balancing algorithm

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
This command displays the use of geometric mean load balancing algorithm.

Examples
cluster1::> network options load-balancing show
Geometric Mean Algorithm for load balancing: false

network options port-health-monitor commands

Manage port health monitor

network options port-health-monitor disable-monitors

Disable one or more port health monitors

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
This command disables the given port health monitors for the given IPspaces in the cluster.

Parameters

- \(-ip\space<IPspace>\) - IPspace Name
  
  The name of the IPspace for which the specified port health monitors are disabled.

- \(-health-monitors \{l2-reachability|link-flapping|crc-errors\},...\) - List of Port Health Monitors to Disable
  
  The port health monitors to disable.

Examples

The following example disables the "l2_reachability" health monitor for the "Default" IPspace.

Note: The status of the "link_flapping" monitor is unaffected by the command.
network options port-health-monitor enable-monitors

Enable one or more port health monitors

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
This command enables the given port health monitors for the given IPspaces in the cluster.

Parameters
-ipspace <IPspace> - IPspace Name
  The name of the IPspace for which the specified port health monitors are enabled.

-health-monitors {l2-reachability|link-flapping|crc-errors}, ... - List of Port Health Monitors to Enable
  The port health monitors to enable. Upon enabling the l2_reachability health monitor, it runs in an "unpromoted" state. While in this state, the monitor does not mark any ports as unhealthy due to the l2_reachability health check. The monitor is promoted in the "Cluster" IPspace when the "Cluster" broadcast domain is found to have passed the l2_reachability health check. An EMS event called "vifmgr.hm.promoted" event is generated when the health monitor is promoted for the IPspace.

Examples
The following example enables the "l2_reachability" health monitor for the "Default" IPspace:

Note: The status of the "link_flapping" monitor is unaffected by the command.
network options port-health-monitor modify

Modify port health monitors configuration

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
This command modifies the enabled port health monitors for the given IPspaces in the cluster.

Parameters
-ipspace <IPspace> - IPspace Name
The name of the IPspace for which enabled port health monitors are modified.

[-health-monitors {l2-reachability|link-flapping|crc-errors},...] - List of Enabled Port Health Monitors
All of the port health monitors that you want to enable. This command enables any port health monitors in this list that are currently disabled, and it disables any currently enabled monitors that are not in this list. Upon enabling the l2_reachability health monitor, it runs in an "unpromoted" state. While in this state, the monitor does not mark any ports as unhealthy due to the l2_reachability health check. The monitor is promoted in the "Cluster" IPspace when the "Cluster" broadcast domain is found to have passed the l2_reachability health check. An EMS event called "vifmgr.hm.promoted" event is generated when the health monitor is promoted for the IPspace.

Examples
The following example modifies the port health monitor configuration of the "Default" IPspace such that only the "link_flapping" port health monitor is enabled for all IPspaces in the cluster.

Note: Only the specified monitor is enabled after the modify command is issued.

```bash
cluster1:*> network options port-health-monitor show
IPspace Enabled Port Health Monitors
------------- ----------------------------------------
Cluster l2_reachability, link_flapping
Default l2_reachability, link_flapping
2 entries were displayed.

cluster1:*> network options port-health-monitor modify -ipspace Default -health-monitors link_flapping

cluster1:*> network options port-health-monitor show
IPspace Enabled Port Health Monitors
------------- ----------------------------------------
Cluster l2_reachability, link_flapping
Default link_flapping
2 entries were displayed.
```
network options port-health-monitor show

Display port health monitors configuration

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
This command displays the enabled port health monitors for the IPspaces in the cluster.

Parameters

{-fields <fieldname>, ...}
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

{-instance }
If you specify the -instance parameter, the command displays detailed information about all fields.

{-ipspace <IPspace> } - IPspace Name
Displays the port health monitors that are enabled only for the given IPspace name.

{-health-monitors {l2-reachability|link-flapping|crc-errors}, ...} - List of Enabled Port Health Monitors
Displays the IPspaces that have the given monitors enabled.

Examples
The following example lists all port health monitors that are enabled for all IPspaces in the cluster.

```
cluster1::*> network options port-health-monitor show
IPspace          Enabled Port Health Monitors
----------------- --------------------
Cluster           l2_reachability,
                 link_flapping
Default           l2_reachability,
                 link_flapping
2 entries were displayed.
```

network options send-soa commands

Manage Send Start of Authority settings

network options send-soa modify

Modify Send SOA settings

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
This command sets the status of sending statement of authority record in the DNS response.

Parameters

{-enable {true|false}} - Enable sending SOA
Setting this parameter to true enables sending the statement of authority (SOA) record in the DNS response. Setting it to false disables sending the statement of authority (SOA) record in the DNS response for the cluster.
Examples

The following example will enable the sending of statement of authority (SOA) in the DNS response.
cluster1::> network options send-soa modify -enable true

The following example will disable the sending of statement of authority (SOA) in the DNS response.
cluster1::> network options send-soa modify -enable false

network options send-soa show
Display Send SOA settings

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
This command displays whether sending the statement of authority record (SOA) in the DNS response is enabled or not.

Examples

cluster1::> network options send-soa show
Enable sending SOA: true

network options switchless-cluster commands
Manage switchless cluster options

network options switchless-cluster modify
Modify switchless cluster network options

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
This command sets whether the cluster network is in switchless or switched mode. A switchless cluster is physically formed by connecting two nodes back-to-back, without a switch between them.

Parameters
[-enabled {true|false}] - Enable Switchless Cluster

This parameter specifies whether the switchless cluster is enabled or not. Setting this parameter to true enables the switchless cluster.

Examples

The following example enables the switchless cluster:
cluster1::*> network options switchless-cluster modify -enabled true
network options switchless-cluster show

Display switchless cluster network options

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
The network options switchless-cluster show command displays the attributes of a switchless cluster.

Examples
The following example displays the attributes of the switchless cluster:

cluster1::*> network options switchless-cluster show
Enable Switchless Cluster: true

network port commands

Manage physical network ports

network port delete

Delete a network port

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
The network port delete command deletes a network port that is no longer physically present on the storage system.

Parameters
-node {<nodename> | local} - Node
This specifies the node on which the port is located.

-port {<netport> | <ifgrp>} - Port
This specifies the port to delete.

Examples
The following example deletes port e0c from a node named node0. The command works only when the port does not physically exist on the storage system.

cluster1::> network port delete -node node0 -port e0c

network port modify

Modify network port attributes

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The network port modify command enables you to change the maximum transmission unit (MTU) setting, autonegotiation setting, administrative duplex mode, and administrative speed of a specified network port.
The MTU of ports that belong to broadcast-domains must be updated through the `broadcast-domain modify` command.

Modification of a port's IPspace will only work before a node is added to a cluster, when the cluster version is below Data ONTAP 8.3, or when the node is offline. To change the IPspace of a port once the node is in a Data ONTAP 8.3 cluster, the port should be added to a broadcast-domain that belongs to that IPspace.

**Parameters**

- `-node <nodename>|local` - Node
  Use this parameter to specify the node on which the port is located.

- `-port <netport>|<ifgrp>` - Port
  Use this parameter to specify the port that you want to modify.

- `-mtu <integer>` - MTU
  The port's MTU setting. The default setting for ports in the "Cluster" IPspace is 9000 bytes. All other ports use a default value of 1500 bytes.

- `-autonegotiate-admin {true|false}` - Auto-Negotiation Administrative
  Whether the port uses Ethernet autonegotiation to determine the highest speed and duplex mode that the port and its endpoint can support. The default setting when you create a port is `true`.

- `-duplex-admin {auto|half|full}` - Duplex Mode Administrative
  The administrative setting for the port's duplex mode. This is the duplex mode that you prefer the port to use. Depending on network limitations, the operational value can be different from the administrative setting. The default setting when you create a port is `full`.

- `-speed-admin {auto|10|100|1000|10000|40000}` - Speed Administrative
  The administrative speed setting, in megabits per second. This is the speed setting that you prefer the port to use. Depending on network limitations, the operational value can be lower than the administrative setting.

- `-flowcontrol-admin {none|receive|send|full}` - Flow Control Administrative
  The administrative flow control setting of the port. This is the flow control setting that you prefer the port to use. Depending on network and port limitations, the operational value can be different from the administrative setting.

- `-up-admin {true|false}` - Up Administrative (privilege: advanced)
  The administrative state of the port. If set to `true`, the port is used if it is operational. If set to `false`, the port is configured down.

- `-ipspace <IPspace>` - IPspace Name
  Use this parameter to specify the IPspace the network port is assigned to. Modification of a port's IPspace will only work before a node is added to a cluster, when the cluster version is below Data ONTAP 8.3, or when the node is offline. To change the IPspace of a port once the node is in a Data ONTAP 8.3 cluster, the port should be added to a broadcast-domain that belongs to that IPspace. If there is an inconsistency between the broadcast-domain and IPspace, this parameter can be set to bring the IPspace into alignment with the broadcast-domain.

- `-ignore-health-status {true|false}` - Ignore Port Health Status (privilege: advanced)
  Use this parameter to specify that the system ignore network port health status of the specified port for the purpose of hosting a logical interface.

**Examples**

The following example modifies port e0a on a node named node0 not to use auto-negotiation, to preferably use half duplex mode, and to preferably run at 100 Mbps.

```
cluster1::> network port modify -node node0 -port e0a -autonegotiate-admin false -duplex-admin half -speed-admin 100
```
network port show

Display network port attributes

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description

The network port show command displays information about network ports. The command output indicates any inactive links, and lists the reason for the inactive status.

Some parameters can have "administrative" and "operational" values. The administrative setting is the preferred value for that parameter, which is set when the port is created or modified. The operational value is the actual current value of that parameter. For example, if the network is underperforming due to network problems, the operational speed value can be lower than the administrative setting.

If the operational duplex mode and speed of a port cannot be determined (for instance, if the link is down), that port's status is listed as undef, meaning undefined.

Parameters

{-fields <fieldname>, ...}

If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use -fields ? to display the fields to specify.

[-health]

Use this parameter to display detailed health information for the specified network ports.

[-instance]

If you specify the -instance parameter, the command displays detailed information about all fields.

[-node <nodename>|local] - Node

Selects the network ports that match this parameter value. Use this parameter with the -port parameter to select a port.

[-port <netport>|<ifgrp>] - Port

Selects the network ports that match this parameter value. If you do not use this parameter, the command displays information about all network ports.

[-link off|up|down] - Link

Selects the network ports that match this parameter value.

[-mtu <integer>] - MTU

Selects the network ports that match this parameter value.

[-autonegotiate-admin {true|false}] - Auto-Negotiation Administrative

Selects the network ports that match this parameter value.

[-autonegotiate-oper {true|false}] - Auto-Negotiation Operational

Selects the network ports that match this parameter value.

[-duplex-admin {auto|half|full}] - Duplex Mode Administrative

Selects the network ports that match this parameter value.

[-duplex-oper {auto|half|full}] - Duplex Mode Operational

Selects the network ports that match this parameter value.

[-speed-admin {auto|10|100|1000|10000|40000}] - Speed Administrative

Selects the network ports that match this parameter value.
[-speed-oper {auto|10|100|1000|10000|40000}] - Speed Operational
  Selects the network ports that match this parameter value.

[-flowcontrol-admin {none|receive|send|full}] - Flow Control Administrative
  Selects the network ports that match this parameter value.

[-flowcontrol-oper {none|receive|send|full}] - Flow Control Operational
  Selects the network ports that match this parameter value.

[-mac <MAC Address>] - MAC Address
  Selects the network ports that match this parameter value.

[-up-admin {true|false}] - Up Administrative (privilege: advanced)
  Selects the network ports that match this parameter value.

[-type {physical|if-group|vlan}] - Port Type
  Selects the network ports that match this parameter value.

[-ifgrp-node <nodename>] - Interface Group Parent Node
  Selects the network ports that match this parameter value.

[-ifgrp-port (<netport>|<ifgrp>)] - Interface Group Parent Port
  Selects the network ports that match this parameter value.

[-ifgrp-distr-func (mac|ip|sequential|port)] - Distribution Function
  Selects the network ports that match this parameter value.

[-ifgrp-mode {multimode|multimode_lacp|singlemode}] - Create Policy
  Selects the network ports that match this parameter value.

[-vlan-node <nodename>] - Parent VLAN Node
  Selects the network ports that match this parameter value.

[-vlan-port (<netport>|<ifgrp>)] - Parent VLAN Port
  Selects the network ports that match this parameter value.

[-vlan-tag <integer>] - VLAN Tag
  Selects the network ports that match this parameter value.

[-remote-device-id <text>] - Remote Device ID
  Selects the network ports that match this parameter value.

[-ipspace <IPspace>] - IPspace Name
  Use this parameter to display information only about the ports that match the IPspace you specify.

[-broadcast-domain <broadcast domain name>] - Broadcast Domain
  Use this parameter to display information only about the ports that match the broadcast-domain you specify.

[-mtu-admin <integer>] - MTU Administrative
  Selects the network ports that match this parameter value.

[-health-status {healthy|degraded}] - Port Health Status
  Use this parameter to display information only about the ports that match the health-status you specify.

[-ignore-health-status {true|false}] - Ignore Port Health Status
  Use this parameter to display information only about the ports that match the ignore-health-status you specify.

[-health-degraded-reasons {l2-reachability|link-flapping|crc-errors},... ] - Port Health Degraded Reasons
  Use this parameter to display information only about the ports that match the degraded-reason you specify.
Examples

The following example displays information about all network ports.

```
cluster1::> network port show
Node: node1

<table>
<thead>
<tr>

network port show-address-filter-info

Print the port's address filter information

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The `network port show-address-filter-info` command displays information about the port's address filter.

Parameters

```
{-fields <fieldname>,...}
```

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.
If you specify the \texttt{-instance} parameter, the command displays detailed information about all fields.

\textbf{[-node <nodename>] - Node}

Use this parameter to specify the node.

\textbf{[-port \{<netport>|<ifgrp>\}] - Port}

Use this parameter to specify the port. For example, e0c.

\textbf{[-num-total <integer>] - Total Number Of Entries}

Use this parameter to specify the total number of entries.

\textbf{[-num-used <integer>] - Number Of Used Entries}

Use this parameter to specify the number of used entries.

\textbf{[-used-entries <text>, ...] - The Used Entries}

Use this parameter to list the used entries.

\section*{Examples}

The following example displays information of the given port's address filter on the specified node of the cluster.

\begin{verbatim}
cluster1:*> network port show-address-filter-info show -node node1 -port e0c
Node: node1
Total Number       Number of
Port      of Address    Used Address     Used Address
Name  Filter Entries  Filter Entries       Filter Entries
----  --------------  --------------   ------------------
e0c             1328               3     U 0 a0 98 40 e 6
                        M 1 80 c2 0 0 e
                        M 1 0 5e 0 0 fb
\end{verbatim}

\section*{Manage broadcast domains}

Manage broadcast domains

Network port broadcast-domain commands. A broadcast domain object is used to define a layer 2 broadcast domain network configuration. It is used to group the ports which belong to the same layer 2 network.

\textbf{network port broadcast-domain add-ports}

Add ports to a layer 2 broadcast domain

\textbf{Availability:} This command is available to \textit{cluster} administrators at the \textit{admin} privilege level.

\textbf{Description}

Add ports to a broadcast domain.

\textbf{Note:} The IPSpace of the ports added will be updated to the IPSpace of the broadcast-domain. The ports will be added to the failover-group of the broadcast-domain. The MTU of the ports will be updated to the MTU of the broadcast-domain.

\textbf{Parameters}

\textbf{--ipspace <IPspace> - IPspace Name}

The IPSpace of the broadcast domain.

\textbf{--broadcast-domain <broadcast domain name> - Layer 2 Broadcast Domain}

The broadcast domain for this port assignment.
-ports <<node>:<port>>, ... - List of ports

The ports to be added to this broadcast domain.

### Examples
The following example adds the port "e0d" on node "cluster1-1" and port "e0d" on node "cluster1-2" to broadcast domain "mgmt" in IPspace "Default".

```
cluster1::> network port broadcast-domain> add-ports -ipspace Default -broadcast-domain mgmt -ports cluster1-1:e0d, cluster1-2:e0d
```

### network port broadcast-domain create
Create a new layer 2 broadcast domain

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**
Create a new broadcast domain.

**Note:** The IPSpace of the ports added will be updated to the IPspace of the broadcast-domain. A failover-group will be generated containing the ports of the broadcast-domain. The MTU of all of the ports in the broadcast-domain will be updated to the MTU specified for the broadcast-domain.

**Parameters**

- `-ipspace <IPspace>` - IPspace Name
  The IPspace to which the new broadcast domain belongs.

- `-broadcast-domain <broadcast domain name>` - Layer 2 Broadcast Domain
  The name of the broadcast domain to be created. The name of the broadcast domain needs to be unique within the IPspace.

- `-mtu <integer>` - Configured MTU
  MTU of the broadcast domain.

- `-ports <<node>:<port>>, ...` - Ports
  The network ports to be added to the broadcast domain. Ports need to be added to the broadcast domain before interfaces can be hosted on the port. By default, no port will be added to the broadcast domain.

### Examples
The following example creates broadcast domain "mgmt" in IPspace "Default" with an MTU of 1500 and network ports e0c from node "gx1" and node "gx2".

```
cluster1::> network port broadcast-domain create -ipspace Default -broadcast-domain mgmt -mtu 1500 -ports gx1:e0c,gx2:e0c
```

### network port broadcast-domain delete
Delete a layer 2 broadcast domain

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**
Delete a broadcast domain that contains no ports.
Parameters

- **ipspace** `<IPspace>` - IPspace Name
  The IPspace to which the broadcast domain belongs

- **broadcast-domain** `<broadcast domain name>` - Layer 2 Broadcast Domain
  The name of the broadcast domain to be deleted.

Examples

The following example deletes the broadcast domain "mgmt" in IPspace "Default".

```
cluster1::network port broadcast-domain> delete -ipspace Default -broadcast-domain mgmt
```

**network port broadcast-domain merge**

Merges two layer 2 broadcast domains

**Availability:** This command is available to cluster administrators at the `admin` privilege level.

**Description**

Merges a broadcast domain into an existing broadcast domain.

Parameters

- **ipspace** `<IPspace>` - IPspace Name
  The IPspace of the broadcast domain.

- **broadcast-domain** `<broadcast domain name>` - Layer 2 Broadcast Domain
  The merging broadcast domain.

- **into-broadcast-domain** `<broadcast domain name>` - Merge with This Layer 2 Broadcast Domain
  The target broadcast domain for the merge operation.

Examples

The following example merges broadcast domain "bd-mgmt" in IPspace "Default" to broadcast domain "bd-data".

```
cluster1::network port broadcast-domain> merge -ipspace Default -broadcast-domain bd-mgmt -into-broadcast-domain bd-data
```

**network port broadcast-domain modify**

Modify a layer 2 broadcast domain

**Availability:** This command is available to cluster administrators at the `admin` privilege level.

**Description**

Modify a broadcast domain.

Parameters

- **ipspace** `<IPspace>` - IPspace Name
  The IPspace to which the broadcast domain belongs.

- **broadcast-domain** `<broadcast domain name>` - Layer 2 Broadcast Domain
  The name of the broadcast domain.
[-mtu <integer>] • Configured MTU
  
  MTU of the broadcast domain.

Examples
  
The following example modifies the mtu attribute of broadcast domain "mgmt" in IPspace "Default" to 1500

    cluster1::network port broadcast-domain*> modify -ipspace Default -broadcast-domain mgmt -mtu 1500

network port broadcast-domain remove-ports

  Remove ports from a layer 2 broadcast domain

Availability: This command is available to cluster administrators at the admin privilege level.

Description
  
  Remove port assignments from a broadcast domain.

Parameters
  
  -ipspace <IPspace> - IPspace Name
    
    The IPspace of the broadcast domain.
  
  -broadcast-domain <broadcast domain name> - Layer 2 Broadcast Domain
    
    The broadcast domain of the ports.
  
  -ports <<node>:<port>>, ... - List of ports
    
    The ports to removed from the broadcast-domain.

Examples
  
The following example removes port "e0d" on node "cluster1-1" and port "e0d" on node "cluster1-2" from broadcast domain "mgmt" in IPspace "Default".

    cluster1::network port broadcast-domain> remove-ports -ipspace Default -broadcast-domain mgmt -ports cluster1-1:e0d, cluster1-2:e0d

network port broadcast-domain rename

  Rename a layer 2 broadcast domain

Availability: This command is available to cluster administrators at the admin privilege level.

Description
  
  Rename a broadcast domain.

Parameters
  
  -ipspace <IPspace> - IPspace Name
    
    The IPspace to which the broadcast domain belongs.
  
  -broadcast-domain <broadcast domain name> - Layer 2 Broadcast Domain
    
    The name of the broadcast domain.
  
  -new-name <text> - New Name
    
    The new name of the broadcast domain.
Examples
The following example renames the broadcast domain named "mgmt" to "mgmt2" in IPspace "Default".

```
  cluster1::network port broadcast-domain> rename -ipspace Default -broadcast-domain mgmt -new-name mgmt2
```

**network port broadcast-domain show**

Display layer 2 broadcast domain information

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**
Display broadcast domain information.

**Parameters**

```
\{ [-fields <fieldname>, ...] \\
  If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified 
  field or fields. You can use '-fields ?' to display the fields to specify.

  [-instance] \\
  If you specify the -instance parameter, the command displays detailed information about all fields.

  [-ipspace <IPspace>] - IPspace Name \\
  Selects the broadcast domains that match the IPspace name.

  [-broadcast-domain <broadcast domain name>] - Layer 2 Broadcast Domain \\
  Selects the broadcast domains that match the broadcast domain name.

  [-mtu <integer>] - Configured MTU \\
  Selects the broadcast domains that match the MTU value. This field is the MTU that was configured by the 
  user, which might be different from the operational MTU.

  [-ports <<node>:<port>>, ...] - Ports \\
  Selects the broadcast domains that contain the network ports. For example, node1:e0a will display broadcast 
  domains that contain node1:e0a network port.

  [-port-update-status {complete|in-progress|error|overridden-while-offline}, ...] - Port Update 
  Status \\
  Selects the broadcast domains that contain the network port status. For example, specifying "error" will 
  display broadcast domains that contain "Error" network port status.

  [-port-update-status-details <text>, ...] - Status Detail Description \\
  Selects the broadcast domains that contain the network port status detail text.

  [-port-update-status-combined {complete|in-progress|error|overridden-while-offline}] - 
  Combined Port Update Status \\
  Selects the broadcast domains that contain the combined network port status. For example, specifying "error" 
  will display broadcast domains that contain a combined network port status of "Error".

  [-failover-groups <failover-group>, ...] - Failover Groups \\
  Selects the broadcast domains that contain the failover groups.

  [-subnet-names <subnet name>, ...] - Subnet Names \\
  Selects the broadcast domains that contain the subnet name or names.
```
Examples
The following example displays general information about broadcast domains.

```
cluster1::> network port broadcast-domain show
IPspace Broadcast
Name   Domain Name   MTU  Port List                     Status Details
------- ----------- ------  ----------------------------- --------------
Cluster Cluster       9000
                node1:e0a                     complete
                node1:e0b                     complete
Default Default       1500
                node1:e0c                     complete
                node1:e0d                     complete
2 entries were displayed.
```

**network port broadcast-domain split**

Splits a layer 2 broadcast domain into two layer 2 broadcast domains.

**Availability:** This command is available to cluster administrators at the `admin` privilege level.

**Description**
Splits ports from a broadcast domain into a new broadcast domain.

The following restrictions apply to this command:

- If the ports are in a failover group, all ports in the failover group must be provided. Use `network interface failover-groups show` to see which ports are in failover groups.

- If the ports have LIFs associated with them, the LIFs cannot be part of a subnet’s ranges and the LIF’s `curr-port` and `home-port` must both be provided. Use `network interface show -fields subnet-name, home-node, home-port, curr-node, curr-port` to see which ports have LIFs associated with them and whether the LIFs are part of a subnet’s ranges. Use `network subnet remove-ranges` with the LIF’s IP address and `-force-update-lif-associations` set to `true` to remove the LIF’s association with a subnet.

**Parameters**

- `-ipspace <IPspace>` - IPspace Name
  The IPspace of the broadcast domain.

- `-broadcast-domain <broadcast domain name>` - Layer 2 Broadcast Domain
  The broadcast domain to split.

- `-new-broadcast-domain <broadcast domain name>` - New Layer 2 Broadcast Domain Name
  The new broadcast domain.

- `-ports <<node>:<port>>, ...` - List of Ports
  The ports to be split from this broadcast domain.

**Examples**

The following example splits port "e0d" on node "cluster1-1" and port "e0d" on node "cluster1-2" from broadcast domain "bd-mgmt" in IPspace "Default" to broadcast domain "bd-data".

```
cluster1::> network port broadcast-domain split -ipspace Default -broadcast-domain bd-mgmt -new-broadcast-domain bd-data -ports cluster1-1:e0d, cluster1-2:e0d
```
network port ifgrp add-port

Add a port to an interface group

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**
The `network port ifgrp add-port` command adds a network port to a port interface group. The port interface group must already exist. You can create a port interface group by using the `network port ifgrp create` command.

The following restrictions apply to port interface groups:

- A port that is already a member of a port interface group cannot be added to another port interface group.
- Cluster ports and management ports cannot be in a port interface group.
- A port to which a logical interface is already bound cannot be added to a port interface group.
- A port that already has an assigned failover role cannot be added to a port interface group.
- A VLAN port cannot be added to a port interface group.
- A port which attaches to a VLAN cannot be added to a port interface group.
- An interface group port cannot be added to a port interface group.
- A port that is assigned to a broadcast domain cannot be added to a port interface group.
- All ports in a port interface group must be physically located on the same node.

**Parameters**

- `-node <nodename> | local` - Node
  The node on which the port interface group is located.

- `-ifgrp <netport> | <ifgrp>` - Interface Group Name
  The port interface group to which a port is to be added.

- `-port <netport>` - Specifies the name of port.
  The network port that is to be added to the port interface group.

**Examples**
The following example adds port e0c to port interface group a1a on a node named node1:

```
cluster1:/> network port ifgrp add-port -node node1 -ifgrp a1a -port e0c
```

**Related references**

- `network port ifgrp create` on page 333
network port ifgrp create

Create a port interface group

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The network port ifgrp create command creates a port interface group. See the documentation for the network port ifgrp add-port command for a list of restrictions on creating port interface groups.

Parameters
- node {<nodename>|local} - Node
  The node on which the port interface group will be created.
- ifgrp {<netport>|<ifgrp>} - Interface Group Name
  The name of the port interface group that will be created. Port interface groups must be named using the syntax "a<number><letter>", where <number> is an integer in the range [0-999] without leading zeros and <letter> is a lowercase letter. For example, "a0a", "a0b", "a1c", and "a2a" are all valid port interface group names.
- distr-func {mac|ip|sequential|port} - Distribution Function
  The distribution function of the port interface group that will be created. Valid values are:
  • mac - Network traffic is distributed based on MAC addresses
  • ip - Network traffic is distributed based on IP addresses
  • sequential - Network traffic is distributed in round-robin fashion from the list of configured, available ports
  • port - Network traffic is distributed based on the transport layer (TCP/UDP) ports
- mode {multimode|multimode_lacp|singlemode} - Create Policy
  The create policy for the interface group that will be created. Valid values are:
  • multimode - Bundle multiple member ports of the interface group to act as a single trunked port
  • multimode_lacp - Bundle multiple member ports of the interface group using Link Aggregation Control Protocol
  • singlemode - Provide port redundancy using member ports of the interface group for failover

Examples
The following example creates a port interface group named a0a on node node0 with a distribution function of ip:

```bash
cluster1:~> network port ifgrp create -node node0 -ifgrp a0a -distr-func ip -mode multimode
```

network port ifgrp add-port on page 332

network port ifgrp delete

Destroy a port interface group

Availability: This command is available to cluster administrators at the admin privilege level.
Description
The network port ifgrp delete command destroys a port interface group. Before deleting a port interface group, remove all ports from it with the network port ifgrp remove-port command.

Note: When you delete an interface group port, it is automatically removed from failover rules and groups to which it belongs.

Parameters
-node {<nodename>|local} - Node
   The node on which the port interface group is located.

-ifgrp {<netport>|<ifgrp>} - Interface Group Name
   The port interface group that will be deleted.

Examples
The following example deletes port interface group a0b from a node named node0.

cluster1::> network port ifgrp delete -node node0 -ifgrp a0b

Related references
network port ifgrp remove-port on page 334

network port ifgrp remove-port
Remove a port from an interface group

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The network port ifgrp remove-port command removes a network port from a port interface group.

Parameters
-node {<nodename>|local} - Node
   The node on which the port interface group is located.

-ifgrp {<netport>|<ifgrp>} - Interface Group Name
   The port interface group from which a port will be removed.

-port <netport> - Specifies the name of port.
   The network port that will be removed from the port interface group.

Examples
The following example removes port e0d from port interface group a1a on a node named node1:

cluster1::> network port ifgrp remove-port -node node1 -ifgrp a1a -port e0d

network port ifgrp show
Display port interface groups

Availability: This command is available to cluster administrators at the admin privilege level.
Description
The `network port ifgrp show` command displays information about port interface groups. By default, it displays information about all port interface groups on all nodes in the cluster.

Parameters

```
{ [-fields <fieldname>, ...]
    If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `'-fields ?'` to display the fields to specify.

  [ -instance ]
    If you specify the `-instance` parameter, the command displays detailed information about all fields.

  [-node <nodename> | local] - Node
    Selects the port interface groups that match this parameter value. Use this parameter with the `-ifgrp` parameter to select information about a specific port interface group.

  [-ifgrp <netport> | <ifgrp>] - Interface Group Name
    Selects the port interface groups that match this parameter value. Use this parameter with the `-node` parameter, to select information about a specific port interface group.

  [-distr-func {mac|ip|sequential|port}] - Distribution Function
    Selects the port interface groups that match this parameter value.

  [-mode {multimode|multimode_lacp|singlemode}] - Create Policy
    Selects the port interface groups that match this parameter value.

  [-mac <MAC Address>] - MAC Address
    Selects the port interface groups that match this parameter value.

  [-activeports {full|partial|none}] - Port Participation
    Selects the port interface groups that match this parameter value. The value "partial" indicates that some but not all of the port interface group's ports are active. the value "full" indicates that all of the port interface group's ports are active.

  [-ports <netport> | <ifgrp>], ...] - Network Ports
    Selects the port interface groups that match this parameter value.

  [-up-ports <netport> | <ifgrp>], ...] - Up Ports
    Selects the port interface groups that match this parameter value. Displays only the ports that are up.

  [-down-ports <netport> | <ifgrp>], ...] - Down Ports
    Selects the port interface groups that match this parameter value. Displays only the ports that are down.
```

Examples

The following example displays information about all port interface groups.

```
cluster1::> network port ifgrp show
            Port     Distribution                Active
            Node    ifgrp    Function     MAC Address    Ports   Ports
            ------  -------  ------------ -------------- ------- ---------------
node0     a0a      ip           b8:f8:7a:20:00 partial e0c
node1     a1a      ip           07:26:60:02:00 full   e0d
```

network port vlan commands

The network port vlan directory
network port vlan create

Create a virtual LAN (VLAN)

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The `network port vlan create` command attaches a VLAN to a network port on a specified node.

Parameters
- **-node** `{<nodename>|local}` - Node
  The node to which the VLAN is to be attached.
  
  **Note:** You cannot attach a VLAN to a cluster port.

- `{ -vlan-name <netport>|<ifgrp> }` - VLAN Name
  The name of the VLAN that is to be attached. This name should be a combination of the name of the port or interface group and the VLAN ID, with a hyphen between, such as "e1c-80".

- `{ -port <netport>|<ifgrp> }` - Associated Network Port
  The network port to which the VLAN is to be attached.

- `{ -vlan-id <integer> }` - Network Switch VLAN Identifier
  The ID tag of the created VLAN.

Examples
This example shows how to create VLAN e1c-80 attached to network port e1c on node1.

```
cluster1::> network port vlan create -node node1 -vlan-name e1c-80
```

network port vlan delete

Delete a virtual LAN (VLAN)

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The `network port vlan delete` command deletes a VLAN from a network port.

Note: When you delete a VLAN port, it is automatically removed from all failover rules and groups that use it.

Parameters
- **-node** `{<nodename>|local}` - Node
  The node from which the VLAN is to be deleted.

- `{ -vlan-name <netport>|<ifgrp> }` - VLAN Name
  The name of the VLAN that is to be deleted

- `{ -port <netport>|<ifgrp> }` - Associated Network Port
  The network port to which the VLAN is to be attached.

- `{ -vlan-id <integer> }` - Network Switch VLAN Identifier
  The ID tag of the deleted VLAN.
Examples
This example shows how to delete VLAN e1c-80 from network port e1c on node1.

    cluster1::> network port vlan delete -node node1 -vlan-name e1c-80

network port vlan show

Display virtual LANs (VLANs)

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The network port vlan show command displays information about network ports that are attached to VLANs. The command output indicates any inactive links and lists the reason for the inactive status.

If the operational duplex mode and speed cannot be determined (for instance, if the link is down), they are listed as undef, meaning undefined.

Parameters
[Int-fields <fieldname>, ...]

If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

[-instance]

If you specify the -instance parameter, the command displays detailed information about all fields.

[-node <nodename]|local] - Node

Selects the VLAN network ports that match this parameter value.

{ [-vlan-name <netport>|<ifgrp>] - VLAN Name

Selects the VLAN network ports that match this parameter value.

[[-port <netport>|<ifgrp>] - Associated Network Port

Selects the VLAN network ports that match this parameter value. If neither this parameter nor -name are used, the command displays information about all network ports.

[-vlan-id <integer>] - Network Switch VLAN Identifier

Selects the VLAN network ports that match this parameter value.

[-mac <MAC Address>] - MAC address

Selects the VLAN network ports that match this parameter value.

Examples

```
cluster1::> network port vlan show
Network Network
Node  VLAN Name Port  VLAN ID   MAC Address
------- ------- ------- -------  ------------------
node1  elb-70  elb    70       00:15:17:76:7b:69
```

network qos-marking commands

The qos-marking directory
network qos-marking modify

Modify the QoS marking values

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The network qos-marking modify command modifies the QoS marking values for different protocols, for each IPspace.

Parameters
- -ipspace <IPspace> - IPspace name
  Use this parameter to specify the IPspace for which the QoS marking entry is to be modified.
- -protocol <text> - Protocol
  Use this parameter to specify the protocol for which the QoS marking entry is to be modified. The possible values are NFS, CIFS, iSCSI, SnapMirror, NDMP, FTP, HTTP-admin, HTTP-filesrv, SSH, Telnet, and SNMP.
- -dscp <integer> - DSCP Marking Value
  Use this parameter to specify the DSCP value. The possible values are 0 to 63.
- -is-enabled {true|false} - Is QoS Marking Enabled
  Use this parameter to enable or disable the QoS marking for the specified protocol and IPspace.

Examples
The following example modifies the QoS marking entry for the NFS protocol in the Default IPspace:

```
cluster1::> network qos-marking modify -ipspace Default -protocol NFS -dscp 10 -is-enabled true
```

network qos-marking show

Display the QoS marking values

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The network qos-marking show command displays the QoS marking values for different protocols, for each IPspace.

Parameters
- [-fields <fieldname>,...]
  Use this parameter to display only certain fields of the QoS marking table.
- [-instance ]
  Use this parameter to display all the fields of the QoS marking table.
- -ipspace <IPspace> - IPspace name
  Use this parameter to display the QoS marking entries for the specified IPspace.
- -protocol <text> - Protocol
  Use this parameter to display the QoS marking entries for the specified protocol. The possible values are NFS, CIFS, iSCSI, SnapMirror, NDMP, FTP, HTTP-admin, HTTP-filesrv, SSH, Telnet, and SNMP.
- -dscp <integer> - DSCP Marking Value
  Use this parameter to display the QoS marking entries matching the specified DSCP value. The possible values are 0 to 63.
[-is-enabled (true|false)] - Is QoS Marking Enabled

Use this parameter to display the QoS marking entries matching the specified flag.

### Examples

The following example displays the QoS marking entries for the Default IPspace.

```
cluster1::> network qos-marking show -ipspace Default
IPspace       Protocol    DSCP  Enabled?
-------------- ------------ ---  ------
Default       CIFS         10    false
               FTP          48    false
               HTTP-admin  48    false
               HTTP-filesrv 10    false
               NDMP         10    false
               NFS          10    true
               SNMP         48    false
               SSH          48    false
               SnapMirror  10    false
               Telnet       48    false
               iSCSI        10    false
```

11 entries were displayed.

---

**network route commands**

Manage routing tables

Network route commands.

**network route create**

Create a static route

**Availability:** This command is available to cluster and Vserver administrators at the admin privilege level.

**Description**

The `network route create` command creates a static route within a Vserver.

**Parameters**

- `-vserver <vserver>` - Vserver Name
  
  Use this parameter to specify the Vserver on which the route is to be created.

- `-destination <IP Address/Mask>` - Destination/Mask
  
  Use this parameter to specify the IP address and subnet mask of the route's destination. The format for this value is: address, slash (/), mask. 0.0.0.0/0 is a valid destination value to create default IPv4 route. And ::/0 is a valid destination value to create default IPv6 route

- `-gateway <IP Address>` - Gateway
  
  Use this parameter to specify the IP address of the gateway server leading to the route's destination.

- `[-metric <integer>]` - Metric
  
  Use this parameter to specify the metric of the route.

### Examples

The following example creates default routes within Vserver vs0 for IPv4 and IPv6.
### network route delete

Delete a static route

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

**Description**
The `network route delete` command deletes a static route from a *Vserver*.

**Parameters**
- `-vserver <vserver>` - *Vserver Name*
  
  Use this parameter to specify the *Vserver* on which the route is to be deleted.

- `-destination <IP Address/Mask>` - *Destination/ Mask*
  
  Use this parameter to specify the IP address and subnet mask of the route's destination. The format for this value is: address, slash (`/`), mask. For example, `0.0.0.0/0` is a correctly formatted value for the `-destination` parameter.

- `-gateway <IP Address>` - *Gateway*
  
  Use this parameter to specify the gateway on which the route is to be deleted.

**Examples**
The following example deletes a route within *Vserver* vs0 for destination `0.0.0.0/0`.

```bash
cluster1::> network route delete -vserver vs0 -destination 0.0.0.0/0
```

### network route show

Display static routes

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

**Description**
The `network route show` command displays a group of static routes within one or more *Vservers*. You can view routes within specified *Vservers*, routes with specified destinations, and routes with specified gateways.

**Parameters**

- `{ [-fields <fieldname>, ...]}
  
  Use this parameter to display only certain fields of the routing tables.

- `[-instance]`
  
  Use this parameter to display all fields of the routing tables.

- `-vserver <vserver>` - *Vserver Name*
  
  Use this parameter to display only routes that have the specified *Vserver* as their origin.

- `-destination <IP Address/Mask>` - *Destination/ Mask*
  
  Use this parameter to display only routes that have the specified IP address and subnet mask as their destination. The format for this value is: address, slash (`/`), mask. The example below has `0.0.0.0/0` as a valid value for the `-destination` parameter.
[-gateway <IP Address>] - Gateway
Use this parameter to display only routes that have the specified IP address as their gateway.

[-metric <integer>] - Metric
Use this parameter to display only routes that have the specified metric.

[-ipspace <IPspace>] - IPspace Name
Use this parameter to optionally specify the IPspace associated with the Vserver. This parameter can be used in conjunction with the Vserver parameter in order to configure the same route across multiple Vservers within an IPspace.

[-address-family {ipv4|ipv6|ipv6z}] - Address family of the route
Use this parameter to display only the routes that have the specified address-family.

Examples
The following example displays information about all routing groups.

```
cluster1::> network route show
(network route show)
Server  Destination     Gateway      Metric
-------  --------------- -------------- -----
node1    0.0.0.0/0      10.61.208.1  20
node2    0.0.0.0/0      10.61.208.1  20
vs0      0.0.0.0/0      10.61.208.1  20
3 entries were displayed.
```

**network route show-lifs**

Show the Logical Interfaces for each route entry

*Availability:* This command is available to cluster and Vserver administrators at the admin privilege level.

**Description**
The network route show-lifs command displays the association of static routes and Logical Interfaces (LIFs) within one or more Vservers. You can view routes within specified Vservers, routes with specified destinations, and routes with specified gateways.

**Parameters**

{ [-fields <fieldname>, ...]  
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use -fields ? to display the fields to specify.

[[-instance]]  
If you specify the -instance parameter, the command displays detailed information about all fields.

[-vserver <vserver>] - Vserver Name
Use this parameter to display only routes that have the specified Vserver as their origin.

[-destination <IP Address/Mask>] - Destination/Mask
Use this parameter to display only routes that have the specified IP address and subnet mask as their destination. The format for this value is: address, slash (/), mask. For example, 0.0.0.0/0 is a valid value for the -destination parameter.

[-gateway <IP Address>] - Gateway
Use this parameter to display only routes that have the specified IP address as their gateway.
Logical Interfaces

Use this parameter to display only the routes that are associated with the specified Logical Interfaces (LIFs).

Address Family

Use this parameter to display only the routes that belong to specified address family.

network route active-entry commands

Active routes
Dynamic network route commands.

network route active-entry show

Display active routes

Availability: This command is available to cluster and Vserver administrators at the advanced privilege level.

Description

The network route active-entry show command displays installed routes on one or more nodes. You can view routes within specified nodes, within specified Vservers, routes in specified subnet groups, and routes with specified destinations.

Parameters

[-fields <fieldname>, ...
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use `-fields ?' to display the fields to specify.

[-verbose]
Use this parameter to display the reference count, use, interface, and Path MTU fields.

[-instance]
If you specify the -instance parameter, the command displays detailed information about all fields.

[-vserver <vserver>]- Vserver Name
Displays the routes that have the specified Vserver as their origin.

[-node <nodename> | local]- Node
Displays the routes from the specified node.

[-address-type {ipv4|ipv6|ipv6z}]- Address Family
Displays the routes that have the specified IP address type.

[-subnet-group <IP Address/Mask>]- Subnet Group
Displays the group of routes that belong to the specified subnet. Routes within the specified subnet group are used first before the default set. The "default" subnet group is a system-provided set of default routes.

[-destination <text>]- Destination
Displays the routes that have the specified IP address or subnet as their destination. The format for the subnet is: <address>/<mask>. IPv6 address includes the scope value after percentage ("%"). 0.0.0.0/0, 169.254.4.60, ff02::%e0a/32 and fe80::250:56ff:fea6:db7c%e0b are valid values for this parameter.

[-interface <text>]- Interface Name
Displays the routes that use the specified interface to transmit packets to the destination. A valid interface has the format of {<netport>|<ifgrp>}, such as "e0a", "e0a-1" and "a0a", or it can be a loopback interface, such as "lo" and "losk".

[-gateway <text>]- Gateway
Displays the routes that have the specified gateway. The gateway can be an IP address, such as "10.10.2.1" and "fe80::1%lo", MAC address, such as "0:5:73:a0:1:7" or refer to a local link, such as "link#3".
[-metric <integer>] - Metric
Displays the routes that have the specified metric.

[-flags <text>] - Flags
Displays the routes that have the specified flags. The type string for "-flags" needs to be one or more of the following {U|G|H|R|D|S|1|2|L|C} in the order shown.

• U - Usable
• G - Gateway
• H - Host
• R - Reject
• D - Dynamic
• S - Static
• 1 - Protocol1
• 2 - Protocol2
• L - Llinfo
• C - Clone
Multiple values can be specified (for example: UHL).

[-reference-count <integer>] - Reference Count
Displays the routes that have the specified reference count in the system.

[-lookup-count <integer>] - Lookup Count
Displays the routes that have the specified use count (the count of lookups for the route).

[-path-mtu <integer>] - Path MTU
Displays the routes that have the specified path maximum transmission unit.

Examples
The following example displays active routes on all nodes in Vserver vs0 with subnet-group 10.10.10.0/24.

```bash
cluster1:*> network route active-entry show -vserver vs0 -subnet-group 10.10.10.0/24
(network route active-entry show)
```

<p>| Vserver: vs0 |
| Node: node1 |
| Subnet Group: 10.10.10.0/24 |</p>
<table>
<thead>
<tr>
<th>Destination</th>
<th>Gateway</th>
<th>Interface</th>
<th>Metric</th>
<th>Flags</th>
</tr>
</thead>
<tbody>
<tr>

network route show on page 340
network routing-groups commands

The network routing-groups directory

network routing-groups create

(DEPRECATED)-Create a routing group

Availability: This command is available to cluster administrators at the admin privilege level.

Description

Note: This command has been deprecated and may be removed from a future version of Data ONTAP. Use the "network route" command set to configure routes instead.

The network routing-groups create command creates a group of static routes. After you have created a routing group, you can add routes to the group by using the network routing-groups route create command.

Parameters

-vserver <vserver> - Vserver Name
  Specifies the node or Vserver on which the routing group will be created.

-routing-group <text> - Routing Group
  Specifies the name of the routing group that you want to create.

-subnet <IP Address/Mask> - Address/Mask
  Specifies the IP address and subnet mask of the routing group's destination. The format for this value is: address, slash ("/"), mask. The example below has 192.0.2.165/24 as a valid value for the -subnet parameter.

-role {cluster|data|node-mgmt|intercluster|cluster-mgmt} - Role
  Defines the role of the routing group. The routing group can be a cluster, data, node management, intercluster, or cluster management routing group. There is no default.

[-metric <integer>] - Metric
  Specifies a hop count for the routing group that you are creating. The default is 20.

Examples

The following example creates a routing group for data from the Vserver node1 with an IP address of 192.0.2.165/24 to a destination server with the IP address of 192.0.2.166.

```
cluster1::network routing-groups> create -vserver node1 -routing-group 192.0.2.166 -subnet 192.0.2.165/24 -role data -metric 20
```

Availability: This command is available to cluster administrators at the admin privilege level.
Description

Note: This command has been deprecated and may be removed from a future version of Data ONTAP. Use the "network route" command set to configure routes instead.

The `network routing-groups delete` command deletes a specified group of static routes.

Note: Before you run this command, you must delete any logical interfaces that are using this routing group. Use the `network interface delete` command to delete any logical interfaces using this group.

Parameters

`-vserver <vserver>` - Vserver Name
Specifies the node or Vserver from which the routing group will be deleted

`-routing-group <text>` - Routing Group
Specifies the name of the routing group that you want to delete.

Examples

The following example deletes a routing group from the Vserver node1 with an IP address of 192.0.2.165/24.

```bash
cluster1::network routing-groups> delete -vserver node1 -routing-group 192.0.2.165/24
```

`network interface delete` on page 285

network routing-groups show

(DEPRECATED)-Display routing groups

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description

Note: This command has been deprecated and may be removed from a future version of Data ONTAP. Use the "network route" command set to configure routes instead.

The `network routing-groups show` command displays a group of static routes. You can view routes originating from specified servers, and routes with specified names, roles, and number of hops.

Parameters

`{ [-fields <fieldname>, ...]`
If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

`| [-instance]`
If you specify the `-instance` parameter, the command displays detailed information about all fields.

`-vserver <vserver>` - Vserver Name
Use this parameter to display the routing groups within the specified vserver.

`-routing-group <text>` - Routing Group
Use this parameter to display the specified routing group.

`-subnet <IP Address/Mask>` - Address/Mask
Use this parameter to display the routing groups within the specified subnet. The format for this value is: address, slash (/), mask. The example below has `192.0.2.165/24` as a valid value for the `-subnet` parameter.
[-role {cluster|data|node-mgmt|intercluster|cluster-mgmt}] - Role
Use this parameter to display the routing groups with the specified role.

[-metric <integer>] - Metric
Use this parameter to display the routing groups with the specified metric.

[-address-family (ipv4|ipv6|ipv6z)] - Address Family
Use this parameter to display the routing groups using the specified IP address family. Only IPv4 and IPv6 non-zoned addresses can be used as value for this parameter. IPv6z addresses should not be used.

Examples
The following example displays a routing group for data from the virtual server node1.

```
cluster1::> network routing-groups show -role data
Routing Server Group     Subnet           Role      Metric
-------- --------- ---------------- --------- -------
node1    d192.0.2.165/24 192.0.2.165/24 data      20
node2    d192.0.2.166/24 192.0.2.166/24 data      20
2 entries were displayed.
```

network routing-groups route commands
The network routing-groups route directory

network routing-groups route create
(DEPRECATED)-Create a static route

Availability: This command is available to cluster administrators at the admin privilege level.

Description
Note: This command has been deprecated and may be removed from a future version of Data ONTAP. Use the "network route" command set to configure routes instead.

The network routing-groups route create command creates a static route within a routing group. You can create routes originating from specified Vservers within a specified routing group, routes with specified gateways, and routes with a specified number of hops.

Parameters
-vserver <vserver> - Vserver Name
Use this parameter to specify the node or Vserver on which the route is to be created.

-routing-group <text> - Routing Group
Use this parameter to specify the name of the routing group within which you want to create the new route.

-destination <IP Address/Mask> - Destination/Mask
Use this parameter to specify the IP address and subnet mask of the route's destination. The format for this value is: address, slash (/"/"), mask. The example below has 0.0.0.0/0 as a valid value for the -destination parameter.

-gateway <IP Address> - Gateway
Use this parameter to specify the IP address of the gateway server leading to the route's destination.

[-metric <integer>] - Metric
Use this parameter to specify the hop count for the route you are creating. The default is 20 hops.
Examples
The following example creates a route within a routing group originating from Vserver node3.

```
cluster1::> network routing-groups route create -vserver node3 -routing-group d192.0.2.167/24 -
destination 0.0.0.0/0 -gateway 10.61.208.1 -metric 10
```

**network routing-groups route delete**

(DEPRECATED)-Delete a static route

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**

- **Note:** This command has been deprecated and may be removed from a future version of Data ONTAP. Use the "network route" command set to configure routes instead.

The `network routing-groups route delete` command deletes a static route from a routing group. You can delete routes originating from specified Vservers, and routes within specified routing groups.

**Parameters**

- **-vserver <vserver>** - Vserver Name
  
  Use this parameter to specify the node or Vserver from which the route will be deleted.

- **-routing-group <text>** - Routing Group
  
  Use this parameter to specify the name of the routing group within which you want to delete the route.

- **-destination <IP Address/Mask>** - Destination/Mask
  
  Use this parameter to specify the IP address and subnet mask of the route you want to delete. The format for this value is: address, slash ("/"), mask. For example, `0.0.0.0/0` is a correctly formatted value for the -destination parameter.

**Examples**

The following example deletes a route within routing group d192.0.2.167/24 originating from Vserver node3.

```
cluster1::> network routing-groups route delete -vserver node3 -routing-group d192.0.2.167/24 -
destination 0.0.0.0/0
```

**network routing-groups route show**

(DEPRECATED)-Display static routes

**Availability:** This command is available to cluster and Vserver administrators at the admin privilege level.

**Description**

- **Note:** This command has been deprecated and may be removed from a future version of Data ONTAP. Use the "network route" command set to configure routes instead.

The `network routing-groups route show` command displays a group of static routes within one or more routing groups. You can view routes originating from specified servers, routes within specified routing groups, routes with specified gateways, and routes with a specified number of hops.
Parameters

{[-fields <fieldname>, ...]}
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use ‘-fields ?’ to display the fields to specify.

{[-instance ]}
If you specify the -instance parameter, the command displays detailed information about all fields.

[-vserver <vserver>] - Vserver Name
Use this parameter to display the routes within the specified vserver.

[-routing-group <text>] - Routing Group
Use this parameter to display the routes within the specified routing group.

[-destination <IP Address/Mask>] - Destination/Mask
Use this parameter to display the routes with the specified destination IP address. The format for this value is: address, slash (“/”), mask. The example below has 0.0.0.0/0 as a valid value for the -destination parameter.

[-gateway <IP Address>] - Gateway
Use this parameter to display the routes with the specified gateway.

[-metric <integer>] - Metric
Use this parameter to display the routes with the specified metric.

[-address-family {ipv4|ipv6|ipv6z}] - Address Family
Use this parameter to display the routes using the specified address family. Only IPv4 and IPv6 non-zoned addresses can be used for this parameter. IPv6z addresses should not be used.

Examples
The following example displays information about all routing groups.

```
cluster1::> network routing-groups route show
<table>
<thead>
<tr>
<th>Server</th>
<th>Group</th>
<th>Destination</th>
<th>Gateway</th>
<th>Metric</th>
</tr>
</thead>
<tbody>
<tr>
<td>node1</td>
<td>d192.0.2.165/24</td>
<td>0.0.0.0/0</td>
<td>10.61.208.1</td>
<td>20</td>
</tr>
<tr>
<td>node2</td>
<td>d192.0.2.166/24</td>
<td>0.0.0.0/0</td>
<td>10.61.208.1</td>
<td>20</td>
</tr>
</tbody>
</table>
2 entries were displayed.
```

network subnet commands
The subnet directory
Network Subnet commands. These commands are used to define a subnet with its gateway and groups of IP addresses. The IP addresses can be used to create interfaces.

network subnet add-ranges
Add new address ranges to a subnet
Availability: This command is available to cluster administrators at the admin privilege level.

Description
Add new address ranges to a subnet.
Note: All addresses in a range must be the same address family (IPv4 or IPv6) and must have the same subnet mask. Ranges that overlap or are next to existing ranges will be merged with the existing ranges.

Parameters
- **-ipspace <IPspace>** - IPspace Name
  The IPspace in which the range resides.

- **-subnet-name <subnet name>** - Subnet Name
  The name of the subnet.

- **-ip-ranges {<ipaddr>|<ipaddr>-<ipaddr>,}** - IP Ranges
  The list of ranges to add to the subnet.

[[-**force-update-lif-associations [true]**] - Force Update LIF Associations
  This command will fail if any service processor interfaces or network interfaces are using the IP addresses in the ranges provided. Using this parameter will associate any manually addressed interfaces with the subnet and will allow the command to succeed.

Examples
The following example allocates addresses for subnet s1 in IPspace Default.

```
cluster1::> network subnet add-ranges -ipspace Default -subnet-name s1
   -ip-ranges "10.98.1.20-10.98.1.30, 10.98.1.35, 10.98.1.40-10.98.1.49"
```

**network subnet create**
Create a new layer 3 subnet

Availability: This command is available to cluster administrators at the admin privilege level.

Description
Create a new subnet.

Parameters
- **-[**-ipspace <IPspace>] - IPspace Name
  The IPspace to which the new subnet belongs.

- **-subnet-name <subnet name>** - Subnet Name
  The name of the subnet to be created. The name of the subnet needs to be unique within the IPspace.

- **-broadcast-domain <broadcast domain name>** - Broadcast Domain
  The broadcast domain to which the new subnet belongs.

- **-subnet <IP Address/Mask>** - Layer 3 Subnet
  The address and mask of the subnet.

- **[**-gateway <IP Address>] - Gateway
  The gateway of the subnet.

- **-[**-ip-ranges {<ipaddr>|<ipaddr>-<ipaddr>,}**...] - IP Addresses or IP Address Ranges
  The IP ranges associated with this subnet.

[[-**force-update-lif-associations [true]**] - Change the subnet association
  This command will fail if any service processor interfaces or network interfaces are using the IP addresses in the ranges provided. Using this parameter will associate any manually addressed interfaces with the subnet and will allow the command to succeed.

network subnet commands
349
Examples

The following examples create subnets named s1 and s6 in IPspace Default.

```
cluster1::> network subnet create -ipspace Default -broadcast-domain bd1 -subnet-name s1
          -subnet 192.168.1.0/24 -gateway 192.168.1.1 -ip-ranges "192.168.1.1-192.168.1.100,
                    192.168.1.112, 192.168.1.145"
```

```
cluster1::> network subnet create -ipspace Default -broadcast-domain bd1 -subnet-name s6
          -subnet 3FFE::/64 -gateway 3FFE::1 -ip-ranges "3FFE::10-3FFE::20"
```

network subnet delete

Delete an existing subnet object

Availability: This command is available to cluster administrators at the admin privilege level.

Description
Delete a subnet that contains no ports.

Parameters
- **-ipspace <IPspace>** - IPspace Name
  The IPspace to which the subnet belongs.
- **-subnet-name <subnet name>** - Subnet Name
  The name of the subnet to be deleted.
- **[-force-update-lif-associations [true]]** - Change the subnet association
  This command will fail if the subnet has ranges containing any existing service processor interface or network interface IP addresses. Setting this value to true will remove the network interface associations with the subnet and allow the command to succeed. However, it will not affect service processor interfaces.

Examples

The following example deletes subnet s1 in IPspace Default.

```
cluster1::> network subnet delete -ipspace Default -subnet-name s1
```

network subnet modify

Modify a layer 3 subnet

Availability: This command is available to cluster administrators at the admin privilege level.

Description
Modify a subnet.

Parameters
- **-ipspace <IPspace>** - IPspace Name
  The IPspace to which the subnet belongs.
- **-subnet-name <subnet name>** - Subnet Name
  The name of the subnet to modify.
[-subnet <IP Address/Mask>] - Layer 3 Subnet
The new address and mask of the subnet.

[-gateway <IP Address>] - Gateway
The new gateway address.

[-ip-ranges (<ipaddr>|<ipaddr>-<ipaddr>), ...] - IP Addresses or IP Address Ranges
The new IP ranges for this subnet.

[-force-update-lif-associations [true]] - Change the subnet association
This command will fail if any existing service processor interfaces or network interfaces are using IP addresses in the IP ranges being added. It will also fail if any existing service processor interfaces or network interfaces are using IP addresses in the IP ranges being removed. Using this parameter will associate the interfaces with the IP addresses in the ranges being added to the subnet. It will also remove the subnet's association with the interfaces with IP addresses in the IP ranges being removed and will allow the command to succeed.

Examples
The following example modifies the subnet address and gateway.

```
cluster1::> network subnet modify -ipspace Default -subnet-name s1 -subnet 192.168.2.0/24 -gateway 192.168.2.1
```

network subnet remove-ranges
Remove address ranges from a subnet

Availability: This command is available to cluster administrators at the admin privilege level.

Description
Remove address ranges from a subnet.

Parameters
-ipspace <IPspace> - IPspace Name
The IPspace in which the range resides.

-subnet-name <subnet name> - Subnet Name
The name of the subnet.

-ip-ranges (<ipaddr>|<ipaddr>-<ipaddr>), ... - IP Ranges
IP ranges to remove.

[-force-update-lif-associations [true]] - Force Update LIF Associations
This command will fail if any existing service processor interfaces or network interfaces are using IP addresses in the ranges provided. Using this parameter will remove the subnet's association with those interfaces and allow the command to succeed.

Examples
The following example removes an address range with starting address of 10.98.1.1 from subnet s1 in IPspace Default.

```
cluster1::> network subnet remove-ranges -ipspace Default -subnet-name s1 -ip-ranges "10.98.1.1-10.98.1.30"
```
network subnet rename

Rename a layer 3 subnet

Availability: This command is available to cluster administrators at the admin privilege level.

Description
Rename a Subnet.

Parameters
- `–ipspace <IPspace>` - IPspace Name
  The IPspace to which the subnet belongs.
- `–subnet-name <subnet name>` - Subnet Name
  The name of the subnet to rename.
- `–new-name <text>` - New Name
  The new name for the subnet.

Examples
The following example renames subnet `s1` to `s3`.

```
cluster1::> network subnet rename -ipspace Default -subnet s1 -new-name s3
```

network subnet show

Display subnet information

Availability: This command is available to cluster administrators at the admin privilege level.

Description
Display subnet information.

Parameters
- `{ [-fields <fieldname>, ...]` If you specify the `–fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use ‘–fields ?’ to display the fields to specify.
- `[-instance ]}` If you specify the `–instance` parameter, the command displays detailed information about all fields.
- `–ipspace <IPspace>` - IPspace Name
  Selects the subnets that match the given IPspace name.
- `–subnet-name <subnet name>` - Subnet Name
  Selects the subnets that match the given subnet name.
- `–broadcast-domain <broadcast domain name>` - Broadcast Domain
  Selects the subnets that match the given broadcast domain name.
- `–subnet <IP Address/Mask>` - Layer 3 Subnet
  Selects the subnets that match the given address and mask.
- `–gateway <IP Address>` - Gateway
  Selects the subnets that match the given gateway address.
network test-link commands

The test-link directory

network test-link run-test

Test link bandwidth

Availability: This command is available to cluster administrators at the advanced privilege level.

Description

The network test-link run-test command runs a performance test between two nodes. The command requires a source node, Vserver, and destination address. All tests are run using intra-cluster LIFs or iSCSI LIFs, depending on whether the test is exercising the one of the intra-cluster LIFs, or an iSCSI LIF used in ONTAP Select or ONTAP Cloud.

The test is built upon the BSD command iPerf3, although it limits the options for simplicity, and adds the framework needed to supply the correct Vserver to use for the requested LIFs. The test itself runs for 10 seconds and sends 128k buffers.

Before executing the network test-link run-test command, the network test-link start-server command must be run to start a server on the node hosting the destination LIF. After all tests to that node are complete the network test-link stop-server command should be run to stop the server.

The test results are stored non-persistently and can be viewed using the network test-link show command. Results include input parameters, the bandwidth achieved, and the date and time of the test.
Parameters

- **node** `<nodename>|local>` - Node Name
  
  Use this parameter to specify the node which initiates the test.

- **vserver** `<vserver>` - Vserver
  
  Use one of the following values to specify the Vserver used to access the destination LIF:
  
  - Cluster: LIFs used for intra-cluster data traffic
  - DC: LIFs used for iSCSI traffic

- **destination** `<Remote InetAddress>` - Destination
  
  Use this parameter to specify the destination IP address.

**Examples**

The following example runs a test between the cluster LIFs, including the start and stop of the server side of the test:

```
cluster1::*> network test-link start-server -node node1
cluster1::*> network test-link run-test -node node2 -vserver Cluster -destination 172.31.112.173

  Node: node2
  Vserver: Cluster
  Destination: 172.31.112.173
  Time of Test: 4/22/2016 15:33:18
  MB/s: 41.2678

cluster1::*> network test-link stop-server -node node1
```

```
cluster1::*> network test-link show

<table>
<thead>
<tr>
<th>Node</th>
<th>Vserver</th>
<th>Destination</th>
<th>Time of Test</th>
<th>MB/s</th>
</tr>
</thead>
<tbody>
<tr>
<td>node2</td>
<td>Cluster</td>
<td>172.31.112.173</td>
<td>4/22/2016 15:33:18</td>
<td>41.2678</td>
</tr>
</tbody>
</table>
```

- `network test-path` on page 260
- `storage iscsi-initiator` on page 841

**network test-link show**

Display test results

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

**Description**

The `network test-link show` command displays the results of prior `network test-link run-test` commands.

The test results are stored non-persistently and can be viewed using the `network test-link show` command. Results include input parameters, the bandwidth achieved, and the date and time of the test.
Parameters

\{-fields <fieldname>, \ldots\}

If you specify the \(-fields <fieldname>, \ldots\) parameter, the command output also includes the specified field or fields. You can use \(-fields ?\) to display the fields to specify.

\[-instance\]{}

If you specify the \(-instance\) parameter, the command displays detailed information about all fields.

\[-node \{<nodename>|local\} - Node\]

Use this parameter to specify only the results of tests run from node. By default, all test results are shown.

\[-vserver <vserver> - Vserver\]

Use this parameter to specify only the results associated with the specified Vserver.

- Cluster: LIFs used for intra-cluster data traffic
- DC: LIFs used for iSCSI traffic

\[-destination <Remote InetAddress> - Destination\]

Use this parameter to specify only the results associated with the specified destination.

\[-timestamp <MM/DD/YYYY HH:MM:SS> - Time of Test\]

Use this parameter to specify only the results associated with the specified timestamp.

\[-bandwidth <double> - MB/s\]

Use this parameter to specify only the results matching the specified bandwidth.

Examples

The following example runs a test between the cluster LIFs twice and then demonstrates the show command results:

```
cluster1::*> network test-link run-test -node node2 -vserver Cluster -destination 172.31.112.173

Node: node2
Vserver: Cluster
Destination: 172.31.112.173
Time of Test: 4/25/2016 10:37:52
MB/s: 29.9946

cluster1::*> network test-link run-test -node node2 -vserver Cluster -destination 172.31.112.173

Node: node2
Vserver: Cluster
Destination: 172.31.112.173
Time of Test: 4/25/2016 10:38:32
MB/s: 39.8192

cluster1::> network test-link*> show

Node                Vserver             Destination       Time of Test          MB/s
-----------------   -----------------   ---------------   -------------------   ------------
```

**network test-link start-server**

Start server for bandwidth test

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

**Description**

The `network test-link start-server` command starts the server side of the `network test-link` test on the designated node.

Only one server at a time can be running for the `network test-link` command on a given node. If the `network test-link start-server` command is issued and a server is already running on the node, then the command is ignored, and the existing server continues to run.

The server started is listening on port 5201.

**Parameters**

- `-node {<nodename>|local}` - *Node Name*
  
  Use this parameter to specify the node where the server is to be started.

**Examples**

The following example starts a server:

```
cluster1:*> network test-link start-server -node node1
```

**Related references**

- `network test-link` on page 353
- `network test-link run-test` on page 353
- `network test-link stop-server` on page 356
- `network test-link show` on page 354

**network test-link stop-server**

Stop server for bandwidth test

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

**Description**

The `network test-link stop-server` command stops the `network test-link` server running on the designated node.

**Parameters**

- `-node {<nodename>|local}` - *Node Name*
  
  Use this parameter to specify the node where the server is to be stopped.

**Examples**

The following example starts a server and stops it:
cluster1::*> network test-link start-server -node node1
cluster1::*> network test-link stop-server -node node1

qos commands

QoS settings

qos policy-group commands

The policy-group directory

qos policy-group create

Create a policy group

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The qos policy-group create command creates a new policy group. You can use a QoS policy group to control a set of storage objects known as "workloads" - LUNs, volumes, files, or Vservers. Policy groups define measurable service level objectives (SLOs) that apply to the storage objects with which the policy group is associated.

After you create a policy group, you use the storage object create command or the storage object modify command to apply the policy group to a storage object.

Parameters

-policy-group <text> - Policy Group Name

  Specifies the name of the policy group. Policy group names must be unique and are restricted to 127 alphanumeric characters including underscores "_" and hyphens ".". Policy group names must start with an alphanumeric character. You use the qos policy-group rename command to change the policy group name.

-vserver <vserver name> - Vserver

  Specifies the data Vserver to which this policy group belongs. You can apply this policy group to only the storage objects contained in the specified Vserver. For example, if you want to apply this policy group to a volume, that volume must belong to the specified Vserver. Using this parameter does not apply the policy group's SLOs to the Vserver. You need to use the vserver modify command if you want to apply this policy group to the Vserver. If the system has only one Vserver, then the command uses that Vserver by default. QoS policy groups cannot belong to Vservers with Infinite Volume.
[=max-throughput <qos_tput>=] - Maximum Throughput

Specifies the maximum throughput for the policy group. A maximum throughput limit specifies the throughput that the policy group must not exceed. It is specified in terms of IOPS or MB/s, or a combination of comma separated IOPS and MB/s, and the range is zero to infinity.

The values entered here are case-insensitive, and the units are base ten. There should be no space between the number and the units. The default value for max-throughput is infinity, which can be specified by the special value "INF". Note that there is no default unit - all numbers except zero require explicit specification of the units.

Two reserved keywords, "none" and "INF", are available for the situation that requires removal of a value, and the situation that needs to specify the maximum available value.

Examples of valid throughput specifications are: "100B/s", "10KB/s", "1gb/s", "500MB/s", "1tb/s", "100iops", "100iops,400KB/s", and "800KB/s,100iops"

Examples

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cluster1::&gt; qos policy-group create p1 -vserver vs1</td>
<td>Creates the &quot;p1&quot; policy group which belongs to Vserver &quot;vs1&quot; with default policy values.</td>
</tr>
<tr>
<td>cluster1::&gt; qos policy-group create p2 -vserver vs1 -max-throughput 500MB/s</td>
<td></td>
</tr>
</tbody>
</table>

Related references

qos policy-group rename on page 359

qos policy-group delete

Delete an existing QoS Policy Group

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The qos policy-group delete command deletes a policy group from a cluster. You cannot delete a policy group if a qos workload associated with storage object is assigned to it unless you use "-force". Using "-force" will delete all the qos workloads for storage objects associated with the specified policy groups.

You can only delete user-defined policy groups. You cannot delete preset policy groups.

Parameters

- policy-group <text> - Policy Group Name
  Specifies the name of the policy group that you want to delete.

[-force [true]] - Force Delete Workloads for the QoS Policy Group (privilege: advanced)
  Specifies whether to delete a policy group along with any underlying workloads.

Examples

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cluster1::&gt; qos policy-group delete p1</td>
<td></td>
</tr>
<tr>
<td>cluster1::&gt; qos policy-group delete p1 -force</td>
<td></td>
</tr>
</tbody>
</table>
qos policy-group modify

Modify a policy group

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**
The qos policy-group modify command modifies a user-created policy group.

**Parameters**

- **-policy-group <text>** - Policy Group Name
  
  Specifies the name of the policy group that you want to modify.

- **[-max-throughput <qos_tput>]** - Maximum Throughput
  
  Specifies the maximum throughput for the policy group. A maximum throughput limit specifies the throughput that the policy group must not exceed. It is specified in terms of IOPS or MB/s, and the range is zero to infinity.

  The values entered here are case-insensitive, and the units are base ten. There should be no space between the number and the units. The default value for max-throughput is infinity, which can be specified by the special value "INF". Note there is no default unit - all numbers except zero require explicit specification of the units.

  Two reserved keywords, "none" and "INF", are available for the situation that requires removal of a value, and the situation that needs to specify the maximum available value.

  Examples of valid throughput specifications are: "100B/s", "10KB/s", "1gb/s", "500MB/s", "1tb/s", and "100iops".

**Examples**

```
cluster1::> qos policy-group modify p1 -max-throughput 10IOPS
```

qos policy-group rename

Rename a policy group

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**
The qos policy-group rename command changes the name of an existing policy group.

**Parameters**

- **-policy-group <text>** - Policy Group Name
  
  Specifies the existing name of the policy group that you want to rename.

- **-new-name <text>** - New Policy Group Name
  
  Specifies the new name of the policy group. Policy group names must be unique and are restricted to 127 alphanumeric characters including underscores "_" and hyphens ".". Policy group names must start with an alphanumeric character.

**Examples**

```
cluster1::> qos policy-group rename -policy-group p1 -new-name p1_new
```
qos policy-group show

Display a list of policy groups

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The qos policy-group show command shows the current settings of the policy groups on a cluster. You can display a list of the policy groups and you can view detailed information about a specific policy group.

Parameters

{ [-fields <fieldname>, ...] 
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

[[-instance]]
If you specify the -instance parameter, the command displays detailed information about all fields.

[-policy-group <text>] - Policy Group Name
Selects the policy groups that match this parameter value
Policy groups define measurable service level objectives (SLOs) that apply to the storage objects with which the policy group is associated.

[-vserver <vserver name>] - Vserver
Selects the policy groups that match this parameter value

[-uuid <UUID>] - Uuid
Selects the policy groups that match this parameter value

[-class {preset|user-defined|system-defined|autovolume}] - Policy Group Class
Selects the policy groups that match this parameter value

[-pgid <integer>] - Policy Group ID
Selects the policy groups that match this parameter value
This uniquely identifies the policy group

[-max-throughput <qos_tput>] - Maximum Throughput
Selects the policy groups that match this parameter value
A maximum throughput limit specifies the throughput (in IOPS or MB/s) that the policy group must not exceed.

[-num-workloads <integer>] - Number of Workloads
Selects the policy groups that match this parameter value.

[-throughput-policy <text>] - Throughput Policy
Selects the policy groups that match this parameter value. You can specify the throughput range in terms of IOPS or data rate. For example, 0-INF, 0-400IOPS, 0-200KB/s, 0-400MB/s.

Examples

<table>
<thead>
<tr>

<td>0</td>
<td>0-500IOPS</td>
</tr>
</tbody>
</table>

cluster1::> qos policy-group show
qos settings commands
QoS settings

qos settings cache commands
Cache QoS settings

qos settings cache modify
Modify the cache policy

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The qos settings cache modify command modifies the existing default caching-policy. The list of caching policies can be obtained from the qos setting cache show -fields cache-setting command.

Parameters
-cache-setting <text> - Cache Policy Name
Valid inputs to this parameter include any one of the listed caching-policies. This command is to be used together with the default parameter. If you use this parameter, the command modifies the specified caching-policy based on the default parameter.

[-default {true|false}] - Is Default?
Valid inputs to this parameter are true and false. Together with cache-setting, this parameter helps set or unset a caching-policy as default.

Examples

```
cluster1::> qos settings cache modify -default true -cache-setting random_read_write-random_write
```

qos settings cache show
Display list of cache policies

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The qos settings cache show shows the current caching-policies, class to which they belong, the number of workloads associated with each of the policies, and whether or not they are set to default. The following external-cache policies are available:

- none - Does not cache any user data or metadata blocks.
- auto - Read caches all metadata and randomly read user data blocks, and write caches all randomly overwritten user data blocks.
- all - Read caches all data blocks read and written. It does not do any write caching.
- **all-random_write** - Read caches all data blocks read and written. It also write caches randomly overwritten user data blocks.
- **all_read** - Read caches all metadata, randomly read, and sequentially read user data blocks.
- **all_read-random_write** - Read caches all metadata, randomly read, and sequentially read user data blocks. It also write caches randomly overwritten user data blocks.
- **all_read_random_write** - Read caches all metadata, randomly read, sequentially read and randomly written user data.
- **all_read_random_write-random_write** - Read caches all metadata, randomly read, sequentially read, and randomly written user data blocks. It also write caches randomly overwritten user data blocks.
- **meta** - Read caches only metadata blocks.
- **meta-random_write** - Read caches all metadata and write caches randomly overwritten user data blocks.
- **noread-random_write** - Write caches all randomly overwritten user data blocks. It does not do any read caching.
- **random_read** - Read caches all metadata and randomly read user data blocks.
- **random_read_write** - Read caches all metadata, randomly read and randomly written user data blocks.
- **random_read_write-random_write** - Read caches all metadata, randomly read, and randomly written user data blocks. It also write caches randomly overwritten user data blocks.

**Note:** Note that in a caching-policy name, a hyphen (-) separates read and write caching policies.

**Parameters**

```
[-fields <fieldname>, ...]  The input to this parameter is one of the following: {cache-setting|class|default|num-workloads}. If you use this parameter, the command displays information related to the specified input field.
```

```
[-instance]  If you use this parameter, the command displays information about the caching-policies in a list format.
```

```
[-cache-setting <text>] - Cache Policy Name  The input to this parameter is any one of the above listed caching-policies. If you use this parameter, the command displays information corresponding to the specified caching-policy.
```

```
[-class {preset|user-defined|system-defined|autovolume}] - Cache Policy Class  The input to this parameter is one of the following: {undefined|preset|user-defined|system-defined|autovolume}. If you use this parameter, the command displays information corresponding to the specified policy-group class.
```

```
[-default {true|false}] - Is Default?  The input to this parameter is true and false. If you use this parameter, the command displays information corresponding to entries that have the specified default value.
```

```
[-num-workloads <integer>] - Number Of Workloads With This Policy  The input to this parameter is an integer. If you use this parameter, the command displays information about policy-groups matching the specified number of workloads.
```

**Examples**

```
cluster1::> qos settings cache show
Policy Name  Class  Num Workloads  Default
-----------  ------  ------------  -------
all         preset  0             false
all-random_write preset  0             false
all_read    preset  0             false
```
qos statistics commands

Qos Statistics

qos statistics latency commands

Latency breakdown

qos statistics latency show

Display latency breakdown data per QoS policy group

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The qos statistics latency show command displays the average latencies for QoS policy groups across the various Data ONTAP subsystems.

The command displays the following data:

• The QoS policy group name (Policy Group)
• Total latency observed per I/O operation (Latency)
• Latency observed per I/O operation in the Network subsystem (Network)
• Latency observed per I/O operation across the internally connected nodes in a Cluster (Cluster)
• Latency observed per I/O operation in the Data management subsystem (Data)
• Latency observed per I/O operation in the Storage subsystem (Disk)
• Latency observed per I/O operation in the QoS subsystem (QoS)
• Latency observed per I/O operation for NVRAM transfer (NVRAM)

The results displayed per iteration are sorted by the Latency field. Each iteration starts with a row that displays the average latency, in microseconds (us) or milliseconds (ms), observed across all QoS policy groups.
Parameters

[-node {<nodename>|local}] - Node

Selects the policy groups that match this parameter value. If you do not specify this parameter, the command displays data for the entire cluster.

[-iterations <integer>] - Number of Iterations

Specifies the number of times the display is refreshed before terminating. If you do not specify this parameter, the command iterates until interrupted by Ctrl-C.

{ [-rows <integer>] } - Number of Rows in the Output

Specifies the number of busiest QoS policy groups to display. Valid values are from 1 to 20. The default value is 10.

[[-policy-group <text>]] - QoS Policy Group Name

Selects the QoS policy group whose name matches the specified value. If you do not specify this parameter, the command displays data for all QoS policy groups.

[-refresh-display {true|false}] - Toggle Screen Refresh Between Each Iteration

Specifies the display style. If true, the command clears the display after each data iteration. If false, the command displays each data iteration below the previous one. The default is false.

Examples

```
cluster1::> qos statistics latency show -iterations 100 -rows 3

qos statistics characteristics commands

Policy Group characterization
qos statistics characteristics show

Display QoS policy group characterization

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The qos statistics characteristics show command displays data that characterizes the behavior of QoS policy groups.

The command displays the following data:

• The QoS policy group name (Policy Group)
• Input/output operations performed per second (IOPS)
• Throughput achieved in kilobytes per second (KB/s) or megabytes per second (MB/s) as appropriate (Throughput)
• Request size in bytes (B) (Request size)
• Read percentage from total I/O (Read)
• Concurrency, which indicates the number of concurrent users generating the I/O traffic (Concurrency)

The results displayed per iteration are sorted by IOPS. Each iteration starts with a row that displays the total IOPS used across all QoS policy groups. Other columns in this row are either totals or averages.

Parameters

[-node {<nodename>|local}] - Node
   Selects the policy groups that match this parameter value. If you do not specify this parameter, the command displays data for the entire cluster.

[-iterations <integer>] - Number of Iterations
   Specifies the number of times the display is refreshed before terminating. If you do not specify this parameter, the command iterates until interrupted by Ctrl-C.

{ [-rows <integer>] - Number of Rows in the Output
   Specifies the number of busiest QoS policy groups to display. Valid values are from 1 to 20. The default value is 10.

| [-policy-group <text>] - QoS Policy Group Name
   Selects the QoS policy group whose name matches the specified value. If you do not specify this parameter, the command displays data for all QoS policy groups.

[-refresh-display {true|false}] - Toggle Screen Refresh Between Each Iteration
   Specifies the display style. If true, the command clears the display after each data iteration. If false, the command displays each data iteration below the previous one. The default is false.

Examples

```
cluster1::> qos statistics characteristics show -iterations 100 -rows 4
Policy Group             IOPS      Throughput Request size  Read Concurrency
-------------------- -------- --------------- ------------  ---- -----------
- total                  31      304.00KB/s       10041B    0%          16
  System-Best-Effort       4           0KB/s           0B    0%           0
vol1                      11       44.00KB/s        4096B    0%          40
vol2                       4      256.00KB/s       65536B    0%          14
vol1vol0                  101        0.00KB/s        0B    0%          0
- total                   37      808.00KB/s       22361B    2%           3
  System-Best-Effort       15           0KB/s           0B    0%           0
```

qos statistics resource commands

Resource utilization

qos statistics resource cpu commands

CPU utilization

qos statistics resource cpu show

Display CPU resource utilization data per QoS policy group

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The qos statistics resource cpu show command displays the CPU utilization for QoS policy groups per node.

The command displays the following data:

• The QoS policy group name (Policy Group)
• CPU utilization observed in percentage (CPU)

The results displayed per iteration are sorted by total CPU utilization. Each iteration starts with a row that displays the total CPU utilization across all QoS policy groups.

Parameters

- `-node <nodename>|local` - Node
  Selects the policy groups that match this parameter value.

- `-iterations <integer>` - Number of Iterations
  Specifies the number of times the display is refreshed before terminating. If you do not specify this parameter, the command iterates until interrupted by Ctrl-C.

- `{ [-rows <integer>] }` - Number of Rows in the Output
  Specifies the number of busiest QoS policy groups to display. Valid values are from 1 to 20. The default value is 10.
<table>
<thead>
<tr>
<th>[-policy-group &lt;text&gt;]</th>
<th>QoS Policy Group Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Selects the QoS policy group whose name matches the specified value. If you do not specify this parameter, the command displays data for all QoS policy groups.</td>
<td></td>
</tr>
</tbody>
</table>

|-refresh-display {true|false} | Toggle Screen Refresh Between Each Iteration |
|-----------------------------|---------------------------------------------|
| Specifies the display style. If true, the command clears the display after each data iteration. If false, the command displays each data iteration below the previous one. The default is false. |

### Examples

```bash
cluster1::> qos statistics resource cpu show -node nodeA -iterations 100 -rows 3
Policy Group       CPU
------------------ ----
-total- (100%)      9%
fast               1%
slow               3%
medium             5%
slow               1%
fast               3%
medium             3%
```

The following example shows the output when the session privilege level is diagnostic.

```bash
cluster1::*> qos statistics resource cpu show -node nodeB -iterations 100 -rows 3
Policy Group       CPU Wafl_exempt Kahuna Network Raid Exempt Protocol
------------------ ----- ----------- ------ ------- ----- ------ --------
-total- (200%)      21%          0%     0%      0%    0%    18%       3%
fast               19%          0%     0%      0%    0%    16%       3%
medium             1%          0%     0%      0%    0%     1%       0%
slow               1%          0%     0%      0%    0%     1%       0%
-total- (200%)      22%          0%     0%      0%    0%    19%       3%
fast               18%          0%     0%      0%    0%    15%       3%
medium             2%          0%     0%      0%    0%     2%       0%
slow               2%          0%     0%      0%    0%     2%       0%
```

The example above displays the total CPU utilization for the 3 QoS policy groups with the highest CPU utilization and it refreshes the display 100 times before terminating.

```bash
cluster1::> qos statistics resource cpu show -node local -iterations 100 -policy-group pg1
Policy Group       CPU
------------------ ----
-total- (100%)      7%
pg1                1%
-total- (100%)      7%
pg1                1%
-total- (100%)      7%
pg1                1%
```

### qos statistics resource disk commands

Disk utilization

### qos statistics resource disk show

Display disk resource utilization data per QoS policy group

**Availability:** This command is available to `cluster` administrators at the `admin` privilege level.
Description
The `qos statistics resource disk show` command displays the disk utilization for QoS policy groups per node. The disk utilization shows the percentage of time spent on the disk during read and write operations. The command displays disk utilization for system-defined policy groups; however, their disk utilization is not included in the total utilization. The command only supports hard disks.

The command displays the following data:

- The QoS policy group name (Policy Group)
- Disk utilization (Disk)
- The number of HDD data disks utilized (Number of HDD Disks)

The results displayed are sorted by total disk utilization. Each iteration starts with a row that displays the total disk utilization across all QoS policy groups.

Parameters
- `-node <nodename>|local` - Node
  Selects the policy groups that match this parameter value.

  `-iterations <integer>` - Number of Iterations
  Specifies the number of times the display is refreshed before terminating. If you do not specify this parameter, the command iterates until interrupted by Ctrl-C.

  `{ -rows <integer> }` - Number of Rows in the Output
  Specifies the number of busiest QoS policy groups to display. Valid values are from 1 to 20. The default value is 10.

  `{ -policy-group <text> }` - QoS Policy Group Name
  Selects the QoS policy group whose name matches the specified value. If you do not specify this parameter, the command displays data for all QoS policy groups.

  `-refresh-display {true|false}` - Toggle Screen Refresh Between Each Iteration
  Specifies the display style. If true, the command clears the display after each data iteration. If false, the command displays each data iteration below the previous one. The default is false.

Examples

```
cluster1::> qos statistics resource disk show -node nodeA -iterations 100 -rows 3
Policy Group | Disk | Number of HDD Disks
------------- | ----- | -------------------
-total-       | 40%   | 27
pg1           | 22%   | 5
slow          | 10%   | 10
fast          | 8%    | 12
_System_Default | 7%   | 20
-total-       | 42%   | 27
pg1           | 22%   | 5
slow          | 12%   | 10
fast          | 8%    | 12
_System_Default | 7%   | 20
```

The example above displays the total disk utilization for the 3 QoS policy groups with the highest disk utilization and it refreshes the display 100 times before terminating.

```
cluster1::> qos statistics resource disk show -node local -iterations 100 -policy-group pg1
Policy Group | Disk | Number of HDD Disks
------------- | ----- | -------------------
-total-       | 3%    | 10
pg1           | 1%    | 24
```

Commands: Manual Page Reference
qos statistics performance commands

System performance

qos statistics performance show

Display system performance data per QoS policy group

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The qos statistics performance show command shows the current system performance levels that QoS policy groups are achieving.

The command displays the following data:

- The QoS policy group name (Policy Group)
- Input/output operations performed per second (IOPS)
- Throughput in kilobytes per second (KB/s) or megabytes per second (MB/s) as appropriate (Throughput)
- Latency observed per request in microseconds (us) or milliseconds (ms) as appropriate (Latency)

The results displayed per iteration are sorted by IOPS. Each iteration starts with a row that displays the total IOPS used across all QoS policy groups. Other columns in this row are either totals or averages.

Parameters

[-node {<nodename>|local}] - Node

Selects the policy groups that match this parameter value. If you do not specify this parameter, the command displays data for the entire cluster.

[-iterations <integer>] - Number of Iterations

Specifies the number of times the display is refreshed before terminating. If you do not specify this parameter, the command iterates until interrupted by Ctrl-C.

{ [-rows <integer>] - Number of Rows in the Output

Specifies the number of busiest QoS policy groups to display. Valid values are from 1 to 20. The default value is 10.

[[-policy-group <text>] - QoS Policy Group Name

Selects the QoS policy group whose name matches the specified value. If you do not specify this parameter, the command displays data for all QoS policy groups.

[[-refresh-display {true|false}] - Toggle Screen Refresh Between Each Iteration

Specifies the display style. If true, the command clears the display after each data iteration. If false, the command displays each data iteration below the previous one. The default is false.
The example above displays the system performance for the 4 QoS policy groups with the highest IOPS and it refreshes the display 100 times before terminating.

The qos statistics volume latency show command displays the average latencies for volumes on Data ONTAP subsystems.

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The qos statistics volume latency show command displays the following data:

- The QoS volume name (Workload)
- The QoS workload ID (ID)
- Total latency observed per I/O operation (Latency)
- Latency observed per I/O operation in the Network subsystem (Network)
- Latency observed per I/O operation across the internally connected nodes in a Cluster (Cluster)
- Latency observed per I/O operation in the Data management subsystem (Data)
- Latency observed per I/O operation in the Storage subsystem (Disk)
- Latency observed per I/O operation in the QoS subsystem (QoS)
- Latency observed per I/O operation for NVRAM transfer (NVRAM)

The results displayed per iteration are sorted by the total latency field. Each iteration starts with a row that displays the average latency, in microseconds (us) or milliseconds (ms) observed across all volumes.

**Parameters**

```bash
[-node {<nodename}|local}] - Node
```

Selects the volumes that match this parameter value. If you do not specify this parameter, the command displays data for the entire cluster.

```bash
{-rows <integer>} - Number of Rows in the Output
```

Specifies the number of busiest QoS policy groups to display. The default setting is 10. The allowed range of values is 1 to 20.

```bash
-<vserver <vserver name} - Vserver Name
```

Specifies the Vserver to which the volume belongs.

```bash
-<volume <volume name}> - Volume Name
```

Selects the latency data that match this parameter value. Enter a complete volume name or press the <Tab> key to complete the name. Wildcard query characters are not supported.

```bash
{-iterations <integer>} - Number of Iterations
```

Specifies the number of times that the command refreshes the display with updated data before terminating. If you do not specify this parameter, the command iterates until interrupted by Ctrl-C.

```bash
{-refresh-display {true|false}} - Toggle Screen Refresh Between Each Iteration
```

Specifies the display style. If true, the command clears the display after each data iteration. If false, the command displays each data iteration below the previous one. The default is false.

**Examples**

```
cluster1::> qos statistics volume latency show -iterations 100 -rows 3

qos statistics commands
qos statistics volume resource commands

The resource directory

qos statistics volume resource cpu commands

The cpu directory

qos statistics volume resource cpu show

Display CPU resource utilization data per volume

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The qos statistics volume resource cpu show command displays the CPU utilization for volumes per node.

The command displays the following data:

- The QoS volume name (Workload)
- The QoS workload ID (ID)
- CPU utilization observed in percentage (CPU)

The results displayed per iteration are sorted by total CPU utilization. Each iteration starts with a row that displays the total CPU utilization across all volumes.

Parameters

- `-node <nodename>|local` - Node
  Selects the volumes that match this parameter value.

  { `-rows <integer>` } - Number of Rows in the Output
  Specifies the number of busiest QoS policy groups to display. The default setting is 10. The allowed range of values is 1 to 20.

  `-vserver <vserver name>` - Vserver Name
  Specifies the Vserver to which the volume belongs.

  `-volume <volume name>` - Volume Name
  Selects the CPU utilization data that match this parameter value. Enter a complete volume name or press the <Tab> key to complete the name. Wildcard query characters are not supported.

  `[ -iterations <integer> ]` - Number of Iterations
  Specifies the number of times the display is refreshed before terminating. If you do not specify this parameter, the command iterates until interrupted by Ctrl-C.

  `[ -refresh-display (true|false) ]` - Toggle Screen Refresh Between Each Iteration
  Specifies the display style. If true, the command clears the display after each data iteration. If false, the command displays each data iteration below the previous one. The default is false.
### Examples

```bash
cluster1::> qos statistics volume resource cpu show -node nodeA -iterations 100 -rows 3
```

<table>
<thead>
<tr>
<th>Workload</th>
<th>ID</th>
<th>CPU</th>
</tr>
</thead>
<tbody>
<tr>
<td>--total-- (100%)</td>
<td>-</td>
<td>9%</td>
</tr>
<tr>
<td>vs0vol1-wid-102</td>
<td>102</td>
<td>5%</td>
</tr>
<tr>
<td>vs0vol2-wid-121</td>
<td>121</td>
<td>2%</td>
</tr>
<tr>
<td>vs2_vol10-wid--</td>
<td>212</td>
<td>2%</td>
</tr>
<tr>
<td>--total-- (100%)</td>
<td>-</td>
<td>8%</td>
</tr>
<tr>
<td>vs0vol1-wid-102</td>
<td>102</td>
<td>5%</td>
</tr>
<tr>
<td>vs0vol2-wid-121</td>
<td>121</td>
<td>2%</td>
</tr>
<tr>
<td>vs2_vol10-wid--</td>
<td>212</td>
<td>1%</td>
</tr>
</tbody>
</table>

The example above displays total CPU utilization for the 3 volumes with the highest CPU utilization and it refreshes the display 100 times before terminating.

```bash
cluster1::> qos statistics volume resource cpu show -node local -vserver vs0 -volume vs0_vol1 -iterations 100
```

<table>
<thead>
<tr>
<th>Workload</th>
<th>ID</th>
<th>CPU</th>
</tr>
</thead>
<tbody>
<tr>
<td>--total-- (100%)</td>
<td>-</td>
<td>2%</td>
</tr>
<tr>
<td>vs0_vol1-wid7..</td>
<td>7916</td>
<td>2%</td>
</tr>
<tr>
<td>--total-- (100%)</td>
<td>-</td>
<td>2%</td>
</tr>
<tr>
<td>vs0_vol1-wid7..</td>
<td>7916</td>
<td>2%</td>
</tr>
<tr>
<td>--total-- (100%)</td>
<td>-</td>
<td>1%</td>
</tr>
<tr>
<td>vs0_vol1-wid7..</td>
<td>7916</td>
<td>1%</td>
</tr>
<tr>
<td>--total-- (100%)</td>
<td>-</td>
<td>2%</td>
</tr>
<tr>
<td>vs0_vol1-wid7..</td>
<td>7916</td>
<td>1%</td>
</tr>
<tr>
<td>--total-- (100%)</td>
<td>-</td>
<td>2%</td>
</tr>
<tr>
<td>vs0_vol1-wid7..</td>
<td>7916</td>
<td>2%</td>
</tr>
</tbody>
</table>

The following example shows the output when the session privilege level is "diagnostic".

```bash
cluster1::*> qos statistics volume resource cpu show -node nodeB -iterations 100 -rows 3
```

<table>
<thead>
<tr>
<th>Workload</th>

### qos statistics volume resource disk commands

The disk directory

#### qos statistics volume resource disk show

Display disk resource utilization data per volume

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**

The qos statistics volume resource disk show command displays the disk utilization for volumes per node. The disk utilization shows the percentage of time spent on the disk during read and write operations. The command only supports hard disks.
The command displays the following data:

- The QoS volume name (Workload)
- The QoS workload ID (ID)
- Disk utilization (Disk)
- The number of HDD data disks utilized (Number of HDD Disks)

The results displayed are sorted by total disk utilization. Each iteration starts with a row that displays the total disk utilization across all volumes.

**Parameters**

- **node** `<nodename>|local` - Node
  Selects the volumes that match this parameter value.

- `[ -rows <integer> ]` - Number of Rows in the Output
  Specifies the number of busiest QoS policy groups to display. The default setting is 10. The allowed range of values is 1 to 20.

- **vserver** `<vserver name>` - Vserver Name
  Specifies the Vserver to which the volume belongs.

- **volume** `<volume name>` - Volume Name
  Selects the disk utilization data that match this parameter value. Enter a complete volume name or press the <Tab> key to complete the name. Wildcard query characters are not supported.

- `[ -iterations <integer> ]` - Number of Iterations
  Specifies the number of times the display is refreshed before terminating. If you do not specify this parameter, the command iterates until interrupted by Ctrl-C.

- `[ -refresh-display {true|false} ]` - Toggle Screen Refresh Between Each Iteration
  Specifies the display style. If true, the command clears the display after each data iteration. If false, the command displays each data iteration below the previous one. The default is false.

**Examples**

```
cluster1::> qos statistics volume resource disk show -node nodeB -iterations 100 -rows 3
<table>
<thead>
<tr>
<th>Workload</th>
<th>ID</th>
<th>Disk</th>
<th>Number of HDD Disks</th>
</tr>
</thead>
<tbody>
<tr>
<td>-total-</td>
<td>100%</td>
<td>30%</td>
<td>4</td>
</tr>
<tr>
<td>vs0vol1-wid101</td>
<td>101</td>
<td>12%</td>
<td>2</td>
</tr>
<tr>
<td>vs0vol2-wid121</td>
<td>121</td>
<td>10%</td>
<td>1</td>
</tr>
<tr>
<td>vol0-wid1002</td>
<td>1002</td>
<td>8%</td>
<td>1</td>
</tr>
<tr>
<td>-total-</td>
<td>100%</td>
<td>30%</td>
<td>4</td>
</tr>
<tr>
<td>vs0vol1-wid101</td>
<td>101</td>
<td>12%</td>
<td>2</td>
</tr>
<tr>
<td>vs0vol2-wid121</td>
<td>121</td>
<td>10%</td>
<td>1</td>
</tr>
</tbody>
</table>

The example above displays total disk utilization for the 3 volumes with the highest disk utilization and it refreshes the display 100 times before terminating.
```

```
cluster1::> qos statistics volume resource disk show -node local -vserver vs0 -volume vs0_vol0 -iterations 100
<table>
<thead>
<tr>
<th>Workload</th>
<th>ID</th>
<th>Disk</th>
<th>Number of HDD Disks</th>
</tr>

Commands: Manual Page Reference
qos statistics volume performance commands

The performance directory

qos statistics volume performance show

Display system performance data per volume

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The qos statistics volume performance show command shows the current system performance that each volume is achieving.

The command displays the following data:

- The QoS volume name (Workload)
- The QoS workload ID (ID)
- Input/output operations performed per second (IOPS)
- Throughput in kilobytes per second (KB/s) or megabytes per second (MB/s) as appropriate (Throughput)
- Latency observed per request in microseconds (us) or milliseconds (ms) as appropriate (Latency)

The results displayed per iteration are sorted by IOPS. Each iteration starts with a row that displays the total IOPS used across all volumes. Other columns in this row are either totals or averages.

Parameters

[-node {<nodename>|local}] - Node
Selects the volumes that match this parameter value. If you do not specify this parameter, the command displays data for the entire cluster.

{ [-rows <integer>] - Number of Rows in the Output
Specifies the number of busiest QoS policy groups to display. The default setting is 10. The allowed range of values is 1 to 20.

| -vserver <vserver name> - Vserver Name
Specifies the Vserver to which the volume belongs.

-volume <volume name> - Volume Name
Selects the performance data that match this parameter value. Enter a complete volume name or press the <Tab> key to complete the name. Wildcard query characters are not supported.

[-iterations <integer>] - Number of Iterations
Specifies the number of times the display is refreshed before terminating. If you do not specify this parameter, the command iterates until interrupted by Ctrl-C.

[-refresh-display {true|false}] - Toggle Screen Refresh Between Each Iteration
Specifies the display style. If true, the command clears the display after each data iteration. If false, the command displays each data iteration below the previous one. The default is false.
Examples

```
cluster1::> qos statistics volume performance show -iterations 100 -rows 3

qos statistics volume characteristics commands

The characteristics directory

qos statistics volume characteristics show

Display volume characteristics

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The qos statistics volume characteristics show command displays data that characterizes the behavior of volumes. The command displays the following data:

- QoS volume name (Workload)
- QoS workload ID (ID)
- Input/output operations per second (IOPS)
- Throughput achieved in kilobytes per second (KB/s) or megabytes per second (MB/s) as appropriate (Throughput)
- Request size in bytes (B) (Request size)
- Read percentage from total IOPS (Read)
• Concurrency, which indicates the number of concurrent users generating the I/O traffic (Concurrency)

The results displayed per iteration are sorted by IOPS. Each iteration starts with a row that displays the total IOPS used across all volumes. Other columns in this row are either totals or averages.

Parameters

[-node {<nodename>|local}] - Node

Selects the volumes that match this parameter value. If you do not specify this parameter, the command displays data for the entire cluster.

{ [ -rows <integer>] - Number of Rows in the Output

Specifies the number of busiest QoS policy groups to display. The default setting is 10. The allowed range of values is 1 to 20.

| -vserver <vserver name> - Vserver Name

Specifies the Vserver to which the volume belongs.

-volume <volume name> - Volume Name

Selects the characteristic data that match this parameter value. Enter a complete volume name or press the <Tab> key to complete the name. Wildcard query characters are not supported.

[-iterations <integer>] - Number of Iterations

Specifies the number of times the display is refreshed before terminating. If you do not specify this parameter, the command iterates until interrupted by Ctrl-C.

[-refresh-display {true|false}] - Toggle Screen Refresh Between Each Iteration

Specifies the display style. If true, the command clears the display after each data iteration. If false, the command displays each data iteration below the previous one. The default is false.

Examples

```
cluster1::> qos statistics volume characteristics show -iterations 100 -rows 3
Workload            ID     IOPS       Throughput Request size Read Concurrency
--------------- ------ -------- ---------------- ------------ ---- -----------

qos statistics workload commands

Detail by workload

qos statistics workload latency commands

Latency breakdown

qos statistics workload latency show

Display latency breakdown data per QoS workload

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The qos statistics workload latency show command displays the average latencies for QoS workloads on Data ONTAP subsystems.

The command displays the following data:

• The QoS workload name (Workload)
• The QoS workload ID (ID)
• Total latency observed per I/O operation (Latency)
• Latency observed per I/O operation in the Network subsystem (Network)
• Latency observed per I/O operation across the internally connected nodes in a Cluster (Cluster)
• Latency observed per I/O operation in the Data management subsystem (Data)
• Latency observed per I/O operation in the Storage subsystem (Disk)
• Latency observed per I/O operation in the QoS subsystem (QoS)
• Latency observed per I/O operation for NVRAM transfer (NVRAM)

The results displayed per iteration are sorted by the total latency field. Each iteration starts with a row that displays the average latency, in microseconds (us) or milliseconds (ms) observed across all QoS workloads.

Parameters

[|-node {<nodename>|local}] - Node
Selects the QOS workloads that match this parameter value. If you do not specify this parameter, the command displays data for the entire cluster.

[|-iterations <integer>] - Number of Iterations
Specifies the number of times that the command refreshes the display with updated data before terminating. If you do not specify this parameter, the command continues to run until you interrupt it by pressing Ctrl-C.

[|-refresh-display {true|false}] - Toggle Screen Refresh Between Each Iteration
Specifies the display style. If true, the command clears the display after each data iteration. If false, the command displays each data iteration below the previous one. The default is false.
[-rows <integer>] - Number of Rows in the Output

Specifies the number of busiest QoS policy groups to display. Valid values are from 1 to 20. The default value is 10.

[-policy-group <text>] - QoS Policy Group Name

Selects the QoS workloads that belong to the QoS policy group specified by this parameter value. If you do not specify this parameter, the command displays data for all QoS workloads.

[-workload <text>] - QoS Workload Name

Selects the QoS workload that match this parameter value. If you do not specify this parameter, the command displays data for all QoS workloads.

[-workload-id <integer>] - QoS Workload ID

Selects the QoS workload that match the QoS workload ID specified by this parameter value.

Examples

```
cluster1::> qos statistics workload latency show -iterations 100 -rows 3

<table>

qos statistics commands
qos statistics workload characteristics commands

Workload characterization

qos statistics workload characteristics show

Display QoS workload characterization

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The qos statistics workload characteristics show command displays data that characterizes the behavior of QoS workloads.

The command displays the following data:

- The QoS workload name (Workload)
- The QoS workload ID (ID)
- Input/output operations performed per second (IOPS)
- Throughput achieved in kilobytes per second (KB/s) or megabytes per second (MB/s) as appropriate (Throughput)
- Request size in bytes (B) (Request size)
- Read percentage from total IOPS (Read)
- Concurrency, which indicates the number of concurrent users generating the I/O traffic (Concurrency)

The results displayed per iteration are sorted by IOPS. Each iteration starts with a row that displays the total IOPS used across all QoS workloads. Other columns in this row are either totals or averages.

Parameters

[-node {<nodename> | local}] - Node

Selects the QOS workloads that match this parameter value. If you do not specify this parameter, the command displays data for the entire cluster.

[-iterations <integer>] - Number of Iterations

Specifies the number of times the display is refreshed before terminating. If you do not specify this parameter, the command iterates until interrupted by Ctrl-C.

[-refresh-display {true | false}] - Toggle Screen Refresh Between Each Iteration

Specifies the display style. If true, the command clears the display after each data iteration. If false, the command displays each data iteration below the previous one. The default is false.

{ [-rows <integer>] - Number of Rows in the Output

Specifies the number of busiest QoS policy groups to display. Valid values are from 1 to 20. The default value is 10.
[-policy-group <text>] - QoS Policy Group Name

Selects the QoS workloads that belong to the QoS policy group specified by this parameter value. If you do not specify this parameter, the command displays data for all QoS workloads.

| [-workload <text>] - QoS Workload Name

Selects the QoS workload that match this parameter value. If you do not specify this parameter, the command displays data for all QoS workloads.

| [-workload-id <integer>] - QoS Workload ID

Selects the QoS workload that match the QoS workload ID specified by this parameter value.

qos statistics commands
qos statistics workload performance commands

System performance

qos statistics workload performance show

Display system performance data per QoS workload

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The qos statistics workload performance show command shows the current system performance that each QoS workload is achieving.

The command displays the following data:
• The QoS workload name (Workload)
• The QoS workload ID (ID)
• Input/output operations performed per second (IOPS)
• Throughput in kilobytes per second (KB/s) or megabytes per second (MB/s) as appropriate (Throughput)
• Latency observed per request in microseconds (us) or milliseconds (ms) as appropriate (Latency)

The results displayed per iteration are sorted by IOPS. Each iteration starts with a row that displays the total IOPS used across all QoS workloads. Other columns in this row are either totals or averages.

Parameters
[-node {<nodename>|local}] - Node
Selects the QOS workloads that match this parameter value. If you do not specify this parameter, the command displays data for the entire cluster.

[-iterations <integer>] - Number of Iterations
Specifies the number of times the display is refreshed before terminating. If you do not specify this parameter, the command iterates until interrupted by Ctrl-C.

[-refresh-display {true|false}] - Toggle Screen Refresh Between Each Iteration
Specifies the display style. If true, the command clears the display after each data iteration. If false, the command displays each data iteration below the previous one. The default is false.

{ [-rows <integer>] - Number of Rows in the Output
Specifies the number of busiest QoS policy groups to display. Valid values are from 1 to 20. The default value is 10.

[-policy-group <text>] - QoS Policy Group Name
Selects the QoS workloads that belong to the QoS policy group specified by this parameter value. If you do not specify this parameter, the command displays data for all QoS workloads.

[[-workload <text>] - QoS Workload Name
Selects the QoS workload that match this parameter value. If you do not specify this parameter, the command displays data for all QoS workloads.
[-workload-id <integer>] - QoS Workload ID
Selects the QoS workload that match the QoS workload ID specified by this parameter value.

Examples

| cluster1::> qos statistics workload performance show -iterations 100 -rows 4 |
|---------------------------------------------------------------|---------------------|---------------------|---------------------|
| Workload            | ID     | IOPS       | Throughput    | Latency |

qos statistics workload resource commands

Resource utilization
**qos statistics workload resource cpu commands**

CPU utilization

**qos statistics workload resource cpu show**

Display CPU resource utilization data per QoS workload

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**

The `qos statistics workload resource cpu show` command displays the CPU utilization for QoS workloads per node.

The command displays the following data:

- The QoS workload name (Workload)
- The QoS workload ID (ID)
- CPU utilization observed in percentage (CPU)

The results displayed per iteration are sorted by total CPU utilization. Each iteration starts with a row that displays the total CPU utilization across all QoS workloads.

**Parameters**

- `-node {<nodename>|local} - Node`  
  Selects the QOS workloads that match this parameter value.

- `[-iterations <integer>] - Number of Iterations`  
  Specifies the number of times the display is refreshed before terminating. If you do not specify this parameter, the command iterates until interrupted by Ctrl-C.

- `[-refresh-display {true|false}] - Toggle Screen Refresh Between Each Iteration`  
  Specifies the display style. If true, the command clears the display after each data iteration. If false, the command displays each data iteration below the previous one. The default is false.

- `[-rows <integer>] - Number of Rows in the Output`  
  Specifies the number of busiest QoS policy groups to display. Valid values are from 1 to 20. The default value is 10.

- `[-policy-group <text>] - QoS Policy Group Name`  
  Selects the QoS workloads that belong to the QoS policy group specified by this parameter value. If you do not specify this parameter, the command displays data for all QoS workloads.

- `[-workload <text>] - QoS Workload Name`  
  Selects the QoS workload that match this parameter value. If you do not specify this parameter, the command displays data for all QoS workloads.

- `[-workload-id <integer>] - QoS Workload ID`  
  Selects the QoS workload that match the QoS workload ID specified by this parameter value.

**Examples**

```
cluster1::> qos statistics workload resource cpu show -node nodeA -iterations 100 -rows 3
Workload           ID   CPU
--------------- ----- ----- 
--total- (100%)     -    9%
vs0-wid-102       102    5%
file-bigvmdk-..   121    2%
vs2_vol0-wid-..   212    2%
```

Commands: Manual Page Reference
The following example shows the output when the session privilege level is "diagnostic".

```
cluster1::*> qos statistics workload resource cpu show -node nodeB -iterations 100 -rows 3
```

<table>

**qos statistics workload resource disk commands**

Disk utilization

**qos statistics workload resource disk show**

Display disk resource utilization data per QoS workload

**Availability:** This command is available to cluster administrators at the admin privilege level.
Description
The `qos statistics workload resource disk show` command displays the disk utilization for QoS workloads per node. The disk utilization shows the percentage of time spent on the disk during read and write operations. The command displays disk utilization for system-defined workloads; however, their disk utilization is not included in the total utilization. The command only supports hard disks.

The command displays the following data:

- The QoS workload name (Workload)
- The QoS workload ID (ID)
- Disk utilization (Disk)
- The number of HDD data disks utilized (Number of HDD Disks)

The results displayed are sorted by total disk utilization. Each iteration starts with a row that displays the total disk utilization across all QoS workloads.

Parameters
- `-node {<nodename>|local}` - Node
  Selects the QoS workloads that match this parameter value.

- `[-iterations <integer>]` - Number of Iterations
  Specifies the number of times the display is refreshed before terminating. If you do not specify this parameter, the command iterates until interrupted by Ctrl-C.

- `[-refresh-display {true|false}]` - Toggle Screen Refresh Between Each Iteration
  Specifies the display style. If true, the command clears the display after each data iteration. If false, the command displays each data iteration below the previous one. The default is false.

- `[-rows <integer>]` - Number of Rows in the Output
  Specifies the number of busiest QoS policy groups to display. Valid values are from 1 to 20. The default value is 10.

- `[-policy-group <text>]` - QoS Policy Group Name
  Selects the QoS workloads that belong to the QoS policy group specified by this parameter value. If you do not specify this parameter, the command displays data for all QoS workloads.

- `[-workload <text>]` - QoS Workload Name
  Selects the QoS workload that match this parameter value. If you do not specify this parameter, the command displays data for all QoS workloads.

- `[-workload-id <integer>]` - QoS Workload ID
  Selects the QoS workload that match the QoS workload ID specified by this parameter value.

Examples
```
cluster1::> qos statistics workload resource disk show -node nodeB -iterations 100 -rows 3

<table>

**qos workload commands**

**QoS workload settings**

**qos workload show**

Display a list of workloads

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**

Shows the current status of workloads on a cluster. Use this command to determine the types of workloads that are currently on a cluster. The types of workloads include: system-defined, preset, and user-defined. The system generates system-defined and preset workloads. You cannot create, modify, or delete these workloads. Also, you can only modify or delete a user-defined workload, but cannot create one

**Parameters**

```
[-fields <fieldname>,...]
```

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.
If you specify the `instance` parameter, the command displays detailed information about all fields.

`-workload <text>` - Workload Name
If you use this parameter, the command displays the workloads that contain the specified workload name.

`-uuid <UUID>` - Workload UUID (privilege: advanced)
If you use this parameter, the command displays the workloads that contain the specified UUID.

`-class {preset|user-defined|system-defined|autovolume}` - Workload Class
If you use this parameter, the command displays the workloads that contain the specified class. The Class options include system-defined, preset, and user-defined.

`-wid <integer>` - Workload ID
If you use this parameter, the command displays the workloads that contain the specified internal workload ID.

`-category <text>` - Workload Category
If you use this parameter, the command displays the workloads that contain the specified category. The category options include Scanner and Efficiency.

`-policy-group <text>` - Policy Group Name
If you use this parameter, the command displays the workloads that match the specified policy group name.

`-read-ahead <text>` - Read-ahead Tunables
If you use this parameter, the command displays the workloads that contain the specified read-ahead cache tunable.

`-vserver <vserver name>` - Vserver
If you use this parameter, the command displays the workloads that match the specified Vserver.

`-volume <volume name>` - Volume
If you use this parameter, the command displays the workloads that match the specified volume.

`-qtree <qtree name>` - Qtree Name
If you use this parameter, the command displays the workloads that match the specified Qtree name.

`-lun <text>` - LUN Name
If you use this parameter, the command displays the workloads that match the specified LUN name.

`-file <text>` - File Path
If you use this parameter, the command displays the workloads that match the specified file path.

**Examples**

```bash
cluster1::> qos workload show -class user-defined

Workload       Wid   Policy Group Vserver  Volume   LUN    Qtree  File Path
-------------- ----- ------------ -------- -------- ------ ------ --------------
vs2-wid100     100   pg1          vs2      -        -      -      -
```

**Security Commands**

The security directory

The security commands enable you to manage security for the management interface.
security snmpusers

Show SNMP users

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The security snmpusers displays the following information about SNMP users:

- User name
- Authentication method
- Hexadecimal engine ID
- Authentication protocol
- Privacy protocol
- Security group

Parameters

{ [-fields <fieldname>, ...] }  
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

[ [-instance ] ]  
If you specify the -instance parameter, the command displays detailed information about all fields.

[-vserver <Vserver Name>] - Vserver
If this parameter is specified, the command displays information only about the SNMP user or users that belong to the specified Vserver.

[-username <text>] - User Name
If this parameter is specified, the command displays information only about the SNMP user with the specified user name.

[-authmethod <text>] - Authentication Method
If this parameter is specified, the command displays information only about the SNMP user or users that use the specified authentication method. Possible values include the following:

- community-SNMP community strings
- usm-SNMP user security model

[-engineid <Hex String>] - Engine Id
If this parameter is specified, the command displays information only about the SNMP user or users that use the specified engine ID, specified in hexadecimal format.

[-authprotocol <text>] - Authentication Protocol
If this parameter is specified, the command displays information only about the SNMP user or users that use the specified authentication protocol.

[-privprotocol <text>] - Privacy Protocol
If this parameter is specified, the command displays information only about the SNMP user or users that use the specified privacy protocol.
If this parameter is specified, the command displays information only about the SNMP user or users that belong to the specified security group.

**Examples**

The following example displays information about all SNMP users:

```
cluster1::> security snmpusers
Protocols Security
Vserver UserName AuthMethod EngineId              Auth Priv Group
---------- -------------- ---------- --------------------- ---- ---- ---------
cluster1   comm1          community  8000031504312d38302d31323334353632
           -    -    readwrite
cluster1   private        community  8000031504312d38302d31323334353632
           -    -    readwrite
vs1        snmpuser1      community  8000031504312d38302d31323334353632
           -    -    readwrite
vs1        snmpuser2      usm 8000031504312d38302d31323334353632
           -    -    readwrite
```

**security certificate commands**

Manage Digital Certificates

**security certificate create**

Create and Install a Self-Signed Digital Certificate

**Availability:** This command is available to cluster and Vserver administrators at the admin privilege level.

**Description**
The security certificate create command creates and installs a self-signed digital certificate, which can be used for server authentication, for signing other certificates by acting as a certificate authority (CA), or for Data ONTAP as an SSL client. The certificate function is selected by the -type field. Self-signed digital certificates are not as secure as certificates signed by a CA. Therefore, they are not recommended in a production environment.

**Parameters**

- `-vserver <Vserver Name>` - Name of Vserver
  
  This specifies the name of the Vserver on which the certificate will exist.

- `-common-name <FQDN or Custom Common Name>` - FQDN or Custom Common Name
  
  This specifies the desired certificate name as a fully qualified domain name (FQDN) or custom common name or the name of a person. The supported characters, which are a subset of the ASCII character set, are as follows:
  
  - Letters a through z, A through Z
  - Numbers 0 through 9
  - Asterisk (*), period (.), underscore (_) and hyphen (-)

  The common name must not start or end with a "-" or a ".". The maximum length is 253 characters.

- `-type <type of certificate>` - Type of Certificate
  
  This specifies the certificate type. Valid values are the following:
- **server** - creates and installs a self-signed digital certificate and intermediate certificates to be used for server authentication

- **root-ca** - creates and installs a self-signed digital certificate to sign other certificates by acting as a certificate authority (CA)

- **client** - includes a self-signed digital certificate and private key to be used for Data ONTAP as an SSL client

```bash
[-subtype <kmip-cert>] - Certificate Subtype
```

This specifies a certificate subtype. This optional parameter can have an empty value (the default). The only valid value is as follows:

- **kmip-cert** - this is a Key Management Interoperability Protocol (KMIP) certificate

```bash
-size <size of requested certificate in bits> - Size of Requested Certificate in Bits
```

This specifies the number of bits in the private key. The larger the value, the more secure is the key. The default is 2048. Possible values include 512, 1024, 1536, 2048 and 3072 when the "FIPS Mode" in "security config" is false. When the "FIPS Mode" is true, the possible values are 2048 and 3072.

```bash
-country <text> - Country Name
```

This specifies the country where the Vserver resides. The country name is a two-letter code. The default is US. Here is the list of country codes: *Country Codes*

```bash
-state <text> - State or Province Name
```

This specifies the state or province where the Vserver resides.

```bash
-locality <text> - Locality Name
```

This specifies the locality where the Vserver resides. For example, the name of a city.

```bash
-organization <text> - Organization Name
```

This specifies the organization where the Vserver resides. For example, the name of a company.

```bash
-unit <text> - Organization Unit
```

This specifies the unit where the Vserver resides. For example, the name of a section or a department within a company.

```bash
-email-addr <mail address> - Contact Administrator's Email Address
```

This specifies the email address of the contact administrator for the Vserver.

```bash
-expire-days <integer> - Number of Days until Expiration
```

This specifies the number of days until the certificate expires. The default is 365 days. Possible values are between 1 and 36510.

```bash
-protocol <protocol> - Protocol
```

This specifies the protocol type. This parameter currently supports only the SSL protocol type. The default is SSL.

```bash
-hash-function <hashing function> - Hashing Function
```

This specifies the cryptographic hashing function for signing the certificate. The default is SHA256. Possible values include SHA1, SHA256, MD5, SHA224, SHA384 and SHA512 when the "FIPS Mode" in "security config" is false. When the "FIPS Mode" is true, the possible values are SHA224, SHA256, SHA384 and SHA512.

### Examples

This example creates a server type, self-signed digital certificate for a Vserver named vs0 at a company whose custom common name is `www.example.com` and whose Vserver name is vs0.
This example creates a root-ca type, self-signed digital certificate with a 2048-bit private key generated by the SHA256 hashing function that will expire in 365 days for a Vserver named vs0 for use by the Software group in IT at a company whose custom common name is www.example.com, located in Sunnyvale, California, USA. The email address of the contact administrator who manages the Vserver is web@example.com.

This example creates a client type of self-signed digital certificate for a Vserver named vs0 at a company that uses Data ONTAP as an SSL client. The company's custom common name is www.example.com and its Vserver name is vs0.

security certificate delete
Delete an Installed Digital Certificate

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
This command deletes an installed digital security certificate.

Parameters

- **-vserver <Vserver Name>** - Name of Vserver
  This specifies the Vserver that contains the certificate.

- **-common-name <FQDN or Custom Common Name>** - FQDN or Custom Common Name
  This specifies the desired certificate name as a fully qualified domain name (FQDN) or custom common name or the name of a person. The supported characters, which are a subset of the ASCII character set, are as follows:
  - Letters a through z, A through Z
  - Numbers 0 through 9
  - Asterisk (*), period (.), underscore (_) and hyphen (-)
  The common name must not start or end with a "-" or a ".". The maximum length is 253 characters.

- **[<serial <text>]]** - Serial Number of Certificate
  This specifies the certificate serial number. The default value is "*".

- **-ca <text>** - Certificate Authority
  This specifies the certificate authority (CA).

- **-type <type of certificate>** - Type of Certificate
  This specifies the certificate type. Valid values are the following:
  - **server** - includes server certificates and intermediate certificates
  - **root-ca** - includes a self-signed digital certificate to sign other certificates by acting as a certificate authority (CA)
- **client-ca** - includes the public key certificate for the root CA of the SSL client. If this client-ca certificate is created as part of a root-ca, it will be deleted along with the corresponding deletion of the root-ca.

- **server-ca** - includes the public key certificate for the root CA of the SSL server to which Data ONTAP is a client. If this server-ca certificate is created as part of a root-ca, it will be deleted along with the corresponding deletion of the root-ca.

- **client** - includes a public key certificate and private key to be used for Data ONTAP as an SSL client.

[-subtypes <kmip-cert>] - Certificate Subtype

This specifies a certificate subtype. This optional parameter can have an empty value (the default). The only valid value is as follows:

- **kmip-cert** - this is a Key Management Interoperability Protocol (KMIP) certificate

### Examples

This example deletes the security certificate for a Vserver named vs0 in a company named www.example.com.

```
cluster1::> security certificate delete -vserver vs0 -common-name www.example.com -ca "Verisign Inc" -type server
```

This example deletes a root-ca type digital certificate for a Vserver named vs0 in a company named www.example.com with serial number 4F57D3D1.

```
cluster1::> security certificate delete -vserver vs0 -common-name www.example.com -ca www.example.com -type root-ca -serial 4F57D3D1
```

### security certificate generate-csr

Generate a Digital Certificate Signing Request

**Availability:** This command is available to cluster and Vserver administrators at the admin privilege level.

**Description:**

This command generates a digital certificate signing request and displays it on the console. A certificate signing request (CSR or certification request) is a message sent securely to a certificate authority (CA) via any electronic media, to apply for a digital identity certificate.

**Parameters**

- **-common-name <FQDN or Custom Common Name>** - FQDN or Custom Common Name

  This specifies the desired certificate name as a fully qualified domain name (FQDN) or custom common name or the name of a person. The supported characters, which are a subset of the ASCII character set, are as follows:

  - Letters a through z, A through Z
  - Numbers 0 through 9
  - Asterisk (*), period (.), underscore (_) and hyphen (-)

  The common name must not start or end with a "." or a ",". The maximum length is 253 characters.

  **[size <size of requested certificate in bits>]** - Size of Requested Certificate in Bits

  This specifies the number of bits in the private key. The higher the value, the more secure is the key. The default is 2048. Possible values include 512, 1024, 1536 and 2048.
This specifies the country where the Vserver resides. The country name is a two-letter code. The default is US.

Here is the list of country codes: Country Codes

- **state <text>** - State or Province Name
  This specifies the state or province where the Vserver resides. For example, the name of a city.

- **locality <text>** - Locality Name
  This specifies the locality where the Vserver resides. For example, the name of a city.

- **organization <text>** - Organization Name
  This specifies the organization where the Vserver resides. For example, the name of a company.

- **unit <text>** - Organization Unit
  This specifies the unit where the Vserver resides. For example, the name of a section or a department within a company.

- **email-addr <mail address>** - Contact Administrator's Email Address
  This specifies the email address of the contact administrator for the Vserver.

- **hash-function <hashing function>** - Hashing Function
  This specifies the cryptographic hashing function for signing the certificate. The default is SHA256. Possible values include SHA1, SHA256 and MD5.

### Examples

This example creates a certificate-signing request with a 2048-bit private key generated by the SHA256 hashing function for use by the Software group in IT at a company whose custom common name is www.example.com, located in Sunnyvale, California, USA. The email address of the contact administrator who manages the Vserver is web@example.com.

```bash
cluster1::> security certificate generate-csr -common-name www.example.com -size 2048 -country US -state California -locality Sunnyvale -organization IT -unit Software -email-addr web@example.com -hash-function SHA256
```

Note: Please keep a copy of your certificate request and private key for future reference.

### security certificate install

Install a Digital Certificate

**Availability:** This command is available to cluster and Vserver administrators at the admin privilege level.
Description
The security certificate install command installs digital security certificates signed by a certificate authority (CA) and the public key certificate of the root CA. Digital security certificates also include the intermediate certificates to construct the chain for server certificates (the server type), client-side root CA certificates (the client-ca type), or server-side root CA certificates (the server-ca type). With FIPS enabled, the following restrictions apply to the certificate getting installed: server/client/server-ca/client-ca: Key size >= 2048, server/client: Hash function (No MD-5, No SHA-1), server-ca/client-ca: (Intermediate CA), Hash Function (No MD-5, No SHA-1), server-ca/client-ca: (Root CA), Hash Function (No MD-5)

Parameters
-vserver <Vserver Name> - Name of Vserver
This specifies the Vserver that contains the certificate.

-type <type of certificate> - Type of Certificate
This specifies the certificate type. Valid values are the following:
- server - includes server certificates and intermediate certificates.
- client-ca - includes the public key certificate for the root CA of the SSL client
- server-ca - includes the public key certificate for the root CA of the SSL server to which Data ONTAP is a client
- client - includes a self-signed or CA-signed digital certificate and private key to be used for Data ONTAP as an SSL client

[-subtype <kmip-cert>] - Certificate Subtype
This specifies a certificate subtype. This optional parameter can have an empty value (the default). The only valid value is as follows:
- kmip-cert - this is a Key Management Interoperability Protocol (KMIP) certificate

[-kmip-server-ip <IP Address>] - IPv4 and IPv6 address
This parameter is applicable only to the kmip-cert subtype. It specifies the IP address of the KMIP server.

Examples
This example installs a CA-signed certificate (along with intermediate certificates) for a Vserver named vs0.

```
cluster1::> security certificate install -vserver vs0 -type server
Please enter Certificate: Press <Enter> when done
-----BEGIN CERTIFICATE-----
MIIB8TCCAzugAwIBAgIBADANBgkqhkiG9w0BAQQQDADBMA0GCSqGSIb3DEQAB
-----END CERTIFICATE-----
Please enter Private Key: Press <Enter> when done
-----BEGIN RSA PRIVATE KEY-----
MIIBPAIBAAJBAMl6ytrK8nQj82UsWEHOET8gk0BFXT+y5MLycsUdxhXhumNNpVf
-----END RSA PRIVATE KEY-----
Do you want to continue entering root and/or intermediate certificates {y|n}: y
```

security certificate commands 395
This example installs a CA certificate for client authentication for a Vserver named vs0.

```
cluster1::> security certificate install -vserver vs0 -type client-ca
```

Please enter Certificate: Press <Enter> when done

-----BEGIN CERTIFICATE-----
MIIDNjCCAp+gAwIBAgIQNhIilsXjOKUgodJfTNcJVDANBgqkqhkiG9w0BAQFADB

A1UEAxMURGhvd3RlIGF1dGwgQ2FwZS5jb20w
-----END CERTIFICATE-----

You should keep a copy of the private key and the CA-signed digital certificate for future reference.

This example installs a CA certificate for server authentication for a Vserver named vs0. In this case, Data ONTAP acts as an SSL client.

```
cluster1::> security certificate install -vserver vs0 -type server-ca
```

Please enter Certificate: Press <Enter> when done

-----BEGIN CERTIFICATE-----
MIIDNjCCAp+gAwIBAgIQNhIilsXjOKUgodJfTNcJVDANBgqkqhkiG9w0BAQFADB

A1UEAxMURGhvd3RlIGF1dGwgQ2FwZS5jb20w
-----END CERTIFICATE-----

You should keep a copy of the signed digital certificate for future reference.
security certificate prepare-to-downgrade

Restore Certificate Management to releases earlier than Data ONTAP 8.3.1.

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The security certificate prepare-to-downgrade command restore Certificate Management to releases earlier than Data ONTAP 8.3.1.

security certificate show

Display Installed Digital Certificates

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
This command displays information about the installed digital certificates. Some details are displayed only when you use the command with the -instance parameter.

Parameters

{ [-fields <fieldname>, ...]  
  If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use `-fields ?' to display the fields to specify.

  [-instance ]  
  If you specify the -instance parameter, the command displays detailed information about all fields.

  [-vserver <Vserver Name>] - Name of Vserver
  Selects the Vserver whose digital certificates you want to display.

  [-common-name <FQDN or Custom Common Name>] - FQDN or Custom Common Name
  Selects the certificates that match this parameter value.

  [-serial <text>] - Serial Number of Certificate
  Selects the certificates that match this parameter value.

  [-ca <text>] - Certificate Authority
  Selects the certificates that match this parameter value.

  [-type <type of certificate>] - Type of Certificate
  Selects the certificates that match this parameter value.

  [-subtype <kmip-cert>] - Certificate Subtype
  Selects the certificate subtype that matches the specified value. The valid values are as follows:
  • kmip-cert - this is a Key Management Interoperability Protocol (KMIP) certificate

  [-size <size of requested certificate in bits>] - Size of Requested Certificate in Bits
  Selects the certificates that match this parameter value.

  [-start <Date>] - Certificate Start Date
  Selects the certificates that match this parameter value.

  [-expiration <Date>] - Certificate Expiration Date
  Selects the certificates that match this parameter value.
[[-public-cert <certificate>]] - Public Key Certificate
Selects the certificates that match this parameter value.

[[-country <text>]] - Country Name
Selects the certificates that match this parameter value.

[[-state <text>]] - State or Province Name
Selects the certificates that match this parameter value.

[[-locality <text>]] - Locality Name
Selects the certificates that match this parameter value.

[[-organization <text>]] - Organization Name
Selects the certificates that match this parameter value.

[[-unit <text>]] - Organization Unit
Selects the certificates that match this parameter value.

[[-email-addr <mail address>]] - Contact Administrator's Email Address
Selects the certificates that match this parameter value.

[[-protocol <protocol>]] - Protocol
Selects the certificates that match this parameter value.

[[-hash-function <hashing function>]] - Hashing Function
Selects the certificates that match this parameter value.

[[-self-signed {true|false}]] - Self-Signed Certificate
Selects the certificates that match this parameter value.

---

Examples

The examples below display information about digital certificates.

```bash
cluster1::> security certificate show
Vserver    Serial Number   Common Name                               Type
---------- --------------- ----------------------------------------- ---------

398 Commands: Manual Page Reference
security certificate sign

Sign a Digital Certificate using Self-Signed Root CA

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
This command signs a digital certificate signing request and generates a certificate using a Self-Signed Root CA certificate in either PEM or PKCS12 format. You can use the `security certificate generate-csr` command to generate a digital certificate signing request.

Parameters
- `vserver <Vserver Name>` - Name of Vserver
  This specifies the name of the Vserver on which the signed certificate will exist.
- `ca <text>` - Certificate Authority to Sign
  This specifies the name of the Certificate Authority that will sign the certificate.
- `ca-serial <text>` - Serial Number of CA Certificate
  This specifies the serial number of the Certificate Authority that will sign the certificate.
- `[-expire-days <integer>]` - Number of Days until Expiration
  This specifies the number of days until the signed certificate expires. The default is 365 days. Possible values are between 1 and 36510.
- `[-format <certificate format>]` - Certificate Format
  This specifies the format of signed certificate. The default value is PEM. Possible values include PEM and PKCS12.
- `[-destination {(ftp|http)://'(hostname|IPv4 Address|IPv6 Address')...}]` - Where to Send File
  This specifies the destination to upload the signed certificate. This option can only be used when the format is PKCS12.
- `[-hash-function <hashing function>]` - Hashing Function
  This specifies the cryptographic hashing function for the self-signed certificate. The default value is SHA256. Possible values include SHA1, SHA256 and MD5.

Examples
This example signs a digital certificate for a Vserver named vs0 using a Certificate Authority certificate that has a ca of www.ca.com and a ca-serial of 4F4EB629 in PEM format using the SHA256 hashing function.

```
cluster1::> security certificate sign -vserver vs0 -ca www.ca.com -ca-serial 4F4EB629 -expire-days 36 -format PEM -hash-function SHA256
```

Please enter Certificate Signing Request(CSR): Press <Enter> when done

---BEGIN CERTIFICATE REQUEST---
MIIBGjCBxQIBADBgMRQwEgYDVQQDEwtleGFtcGxlLmNvbTELMAkGA1UEBhMCVVMxCTAHBgNVBAgTADEJMAcGA1UEBxMAMQkwBwYDVQQKEwAxCTAHBgNVBAsTADEPMA0GCSqGSIb3DQEJARYAMFwwDQYJKoZIhvcNAQEB

---END CERTIFICATE REQUEST---

security certificate commands

This example signs and exports a digital certificate to destination ftp://10.98.1.1//u/sam/sign.pfx for a Vserver named vs0 using a Certificate Authority certificate that expires in 36 days and has a ca value of www.ca.com and a ca-serial value of 4F4EB629 in PKCS12 format by the MD5 hashing function.

cluster1::> security certificate sign -vserver vs0 -ca www.ca.com -ca-serial 4F4EB629 -expire-days 36 -format PKCS12 -destination ftp://10.98.1.1//u/sam/sign.pfx -hash-function MD5
Please enter Certificate Signing Request (CSR): Press <Enter> when done

security certificate ca-issued commands
Show Digital Certificates Issued by Self-Signed CA

security certificate ca-issued revoke
Revoke a Digital Certificate

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
This command revokes a digital certificate signed by a Self-Signed Root CA.

Parameters
-\texttt{-vserver <Vserver Name> - Vserver}
  This specifies the name of the Vserver on which the certificate is stored.

-\texttt{-serial <text> - Serial Number of Certificate}
  This specifies the serial number of the certificate.

-\texttt{-ca <text> - Certificate Authority}
  This specifies the name of the Certificate Authority whose certificate will be revoked.

-\texttt{-ca-serial <text> - Serial Number of CA Certificate}
  This specifies the serial number of Certificate Authority.

-\texttt{[\texttt{-common-name <FQDN or Custom Common Name>]} - FQDN or Custom Common Name}
  This specifies a fully qualified domain name (FQDN) or custom common name or the name of a person. This field is optional if ca-serial is specified.

Examples
This example revokes a signed digital certificate for a Vserver named vs0 with serial as 4F5A2DF2 for a Certificate Authority certificate that has a ca of www.ca.com and a ca-serial of 4F4EB629.

\begin{verbatim}
cluster1::> security certificate ca-issued revoke -vserver vs0 -serial 4F5A2DF2 -ca www.ca.com -ca-serial 4F4EB629
\end{verbatim}

security certificate ca-issued show
Display CA-Issued Digital Certificates

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
This command displays the following information about the digital certificates issued by the self-signed root-ca:

- Vserver
- Serial number of certificate
- FQDN or custom common name or the name of a person
- Serial number of CA certificate
- Status (active, revoked)
- Certificate Authority
• Expiration date
• Revocation date

To display more details, run the command with the `-instance` parameter. This will add the following information:

• Country name
• State or province name
• Locality name
• Organization name
• Organization unit
• Contact administrator's email address

**Parameters**

```bash
[-fields <fieldname>, ...]
If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

[-instance]
If you specify the `-instance` parameter, the command displays detailed information about all fields.

[-vserver <Vserver Name>] - Vserver
Selects the certificates that match this parameter value.

[-serial <text>] - Serial Number of Certificate
Selects the certificates that match this parameter value.

[-ca <text>] - Certificate Authority
Selects the certificates that match this parameter value.

[-ca-serial <text>] - Serial Number of CA Certificate
Selects the certificates that match this parameter value.

[-common-name <FQDN or Custom Common Name>] - FQDN or Custom Common Name
Selects the certificates that match this parameter value.

[-status <status of certificate>] - Status of Certificate
Selects the certificates that match this parameter value. Possible values include active and revoked.

[-expiration <Date>] - Certificate Expiration Date
Selects the certificates that match this parameter value.

[-revocation <Date>] - Certificate Revocation Date
Selects the certificates that match this parameter value.

[-country <text>] - Country Name (2 letter code)
Selects the certificates that match this parameter value.

[-state <text>] - State or Province Name (full name)
Selects the certificates that match this parameter value.

[-locality <text>] - Locality Name (e.g. city)
Selects the certificates that match this parameter value.

[-organization <text>] - Organization Name (e.g. company)
Selects the certificates that match this parameter value.
[-unit <text>] - Organization Unit (e.g. section)
Selects the certificates that match this parameter value.

[-email-addr <mail address>] - Email Address (Contact Name)
Selects the certificates that match this parameter value.

**Examples**

The examples below display information about CA issued digital certificates.

```
cluster1::> security certificate ca-issued show

**security audit commands**

Manage administrative audit logging settings

**security audit modify**

Set administrative audit logging settings

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**
The `security audit modify` command modifies the following audit-logging settings for the management interface:

- Whether get requests for the CLI are audited
- Whether get requests for the Data ONTAP API (ONTAPI) are audited
**Parameters**

[-cliget {on|off}] - Enable auditing of CLI get operations

This specifies whether get requests for the CLI are audited. The default setting is off.

[-ontapiget {on|off}] - Enable auditing of Data ONTAP API get operations

This specifies whether get requests for the Data ONTAP API (ONTAPI) interface are audited. The default setting is off.

**Examples**

The following example turns off auditing of get requests for the CLI interface:

```
cluster1::> security audit modify -cliget off
```

**security audit show**

Show administrative audit logging settings

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**

The `security audit show` command displays the following audit-logging settings for the management interface:

- Whether get requests for the CLI are audited
- Whether get requests for the Data ONTAP API (ONTAPI) are audited

Audit log entries are written to the 'audit' log, viewable via the 'security audit log show' command.

**Examples**

The following example displays the audit-logging settings for the management interface:

```
cluster1::> security audit show
Auditing State for Get Requests:
      ------------
    CLI:  off
    ONTAPI: on
```

**security audit log commands**

Display administrative audit logging entries

**security audit log show**

Display audit entries merged from multiple nodes in the cluster

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**

The `security audit log show` command displays cluster-wide audit log messages. Messages from each node are interleaved in chronological order.
Parameters
{[-fields <fieldname>, ...]
    If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use -fields ? to display the fields to specify.

| [-instance ]|
    If you specify the -instance parameter, the command displays detailed information about all fields.

[-timestamp <Date>] - Log Entry Timestamp
    Selects the entries that match the specified input for timestamp. This will be in the local timezone.

[-node {<nodename>|local}] - Node
    Selects the entries that match the specified input for node.

[-entry <text>] - Log Message Entry
    Selects the entries that match the specified input for entry.

security config commands
Manage Cluster Security Configuration

security config modify
Modify Security Configuration Options

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
The security config modify command modifies the existing cluster-wide security configuration. If you enable FIPS-compliant mode, the cluster will automatically select only TLS protocols. Use the -supported-protocols parameter to include or exclude TLS protocols independently from the FIPS mode. By default, FIPS mode is disabled, and Data ONTAP supports the TLSv1.2, TLSv1.1 and TLSv1 protocols. For backward compatibility, Data ONTAP supports adding SSLv3 to the supported-protocols list when FIPS mode is disabled. Use the -supported-ciphers parameter to configure only AES, or AES and 3DES, or disable weak ciphers such as RC4 by specifying !RC4. By default the supported-cipher setting is ALL:!LOW:!aNULL:!EXP:!eNULL. This setting means that all supported cipher suites for the protocols are enabled, except the ones with no authentication, no encryption, no exports, and low encryption cipher suites (currently those using 64-bit or 56-bit encryption algorithms). Select a cipher suite which is available with the corresponding selected protocol. An invalid configuration may cause some functionality to fail to operate properly. Refer to "https://www.openssl.org/docs/apps/ciphers.html" published by the OpenSSL software foundation for the correct cipher string syntax. After modifying the security configuration, reboot all the nodes manually.

Parameters
-interface <SSL> - FIPS-Compliant Interface
    Selects the FIPS-compliant interface. Default is SSL.

[-is-fips-enabled {true|false}] - FIPS Mode
    Enables or disables FIPS-compliant mode for the entire cluster. Default is false.

[-supported-protocols {TLSv1.2|TLSv1.1|TLSv1|SSLv3}, ...] - Supported Protocols
    Selects the supported protocols for the selected interface. Default is TLSv1.2, TLSv1.1, TLSv1

[-supported-ciphers <text>] - Supported Ciphers
    Selects the supported cipher suites for the selected interface. Default is ALL:!LOW:!aNULL:!EXP:!eNULL.
Examples
The following command enables FIPS mode in the cluster. (Default setting for FIPS mode is false)

```
cluster1::> security config modify -interface SSL -is-fips-enabled true
```

The following command modifies supported protocols to TLSv1.2 and TLSv1.1 in the cluster. (Default setting for supported protocols is TLSv1.2, TLSv1.1, TLSv1)

```
cluster1::*> security config modify -interface SSL -supported-protocols TLSv1.2, TLSv1.1
```

The following command modifies supported ciphers to ALL:!LOW:!aNULL:!EXP:!eNULL:!RC4 in the cluster. (Default setting for supported ciphers is ALL:!LOW:!aNULL:!EXP:!eNULL)

```
cluster1::*> security config modify -interface SSL -supported-ciphers ALL:!LOW:!aNULL:!EXP:!eNULL:!RC4
```

security config show

Display Security Configuration Options

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
The security config show command displays the security configurations of the cluster in advanced privilege mode.

Default values are as follows:

- SSL FIPS mode: disabled
- Supported protocols: TLSv1.2, TLSv1.1, TLSv1
- Supported ciphers: ALL:!LOW:!aNULL:!EXP:!eNULL

The default cipher suites represent all suites for the listed protocols except those that have no authentication, no encryption, no exports, and low encryption (below 64 or 56 bit).

Enabling FIPS mode will cause the entire cluster to use FIPS-compliant crypto operations only.

Use the security config modify command to change the protocols and ciphers that the cluster will support. When all the nodes in the cluster are updated with the modified settings, the cluster security config ready value will be shown as yes.

Parameters

```
[-fields <fieldname>, ...]
```

If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

```
[-instance]]
```

If you specify the -instance parameter, the command displays detailed information about all fields.

```
[-interface <SSL>] - FIPS-Compliant Interface
```

Displays configurations that match the specified value for the interface.

```
[-is-fips-enabled {true|false}] - FIPS Mode
```

Display configurations that match the specified value for FIPS mode.

```
[-supported-protocols {TLSv1.2|TLSv1.1|TLSv1|SSLv3}, ...] - Supported Protocols
```

Displays configurations that match the specified protocols.
Supported Ciphers

Displays the configurations that match the specified supported ciphers.

Examples

The following example shows the default security configurations for a cluster.

```
cluster1::> security config show

<table>
<thead>
<tr>
<th>Interface</th>
<th>FIPS Mode</th>
<th>Supported Protocols</th>
<th>Supported Ciphers</th>
<th>Config Ready</th>
</tr>
</thead>
<tbody>
<tr>
<td>SSL</td>
<td>false</td>
<td>TLSv1.2, TLSv1.1, TLSv1</td>
<td>ALL:!LOW: !aNULL:!EXP: !eNULL</td>
<td>yes</td>
</tr>
</tbody>
</table>
```

The following example shows the security configuration after FIPS mode has been enabled.

```
cluster1::> security config show

<table>
<thead>
<tr>
<th>Interface</th>
<th>FIPS Mode</th>
<th>Supported Protocols</th>
<th>Supported Ciphers</th>
<th>Config Ready</th>
</tr>
</thead>
<tbody>
<tr>
<td>SSL</td>
<td>true</td>
<td>TLSv1.2, TLSv1.1</td>
<td>ALL:!LOW: !aNULL:!EXP: !eNULL:!RC4</td>
<td>yes</td>
</tr>
</tbody>
</table>
```

Display Security Configuration Status

Availability: This command is available to cluster administrators at the advanced privilege level.

Description

The security config status show command displays the required reboot status of the nodes in the cluster after security configuration settings have been modified using the security config modify command. Use this command to monitor the status of the required reboot process. When all nodes have rebooted, the cluster is ready to use the new security configuration settings.

Parameters

```
[-fields <fieldname>, ...]
```

If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use ‘-fields ?’ to display the fields to specify.

```
[-instance ]
```

If you specify the -instance parameter, the command displays detailed information about all fields.

```
[-node (<nodename>| local)] - Node Name
```

Select the node whose reboot-status you want to display.

```
[-reboot-needed (true|false)] - Reboot Needed
```

reboot-needed status of the node that tells if the node requires a reboot for security configuration to take effect.
Examples

The following example displays the status of a configuration change in a four-node cluster.

```
cluster1::> security config status show
Nodes in Cluster      Reboot Needed
------------------------------- -------------------
node1                 true
node2                 true
node3                 false
node4                 false
4 entries were displayed.
```

The following example shows the output of the command after the cluster reboot process is complete.

```
cluster1::> security config status show
Nodes in Cluster      Reboot Needed
------------------------------- -------------------
node1                 false
node2                 false
node3                 false
node4                 false
4 entries were displayed.
```

security key-manager commands

Manage Key Management Servers

security key-manager add

Add a key management server

Availability: This command is available to cluster administrators at the admin privilege level.

Description

This command adds a key management server at the indicated IP address to its list of four possible active key management servers. The command fails on the node if it already has four active key management servers, or if required SSL certificates are missing or invalid. This command is not supported when onboard key management is enabled.

Parameters

- `-address <IP Address>` - Key Manager IP Address

  This parameter specifies the IP address of the key management server you want to use to store authentication keys.

Examples

```
cluster1::> security key-manager add -address 10.233.1.198
(security key-manager add)
Node: cluster1
Found client CA certificate.
Registering key server...
Key manager registration successful.
```
security key-manager create-key

Create a new authentication key

Availability: This command is available to cluster administrators at the admin privilege level.

Description
This command creates a new authentication key (AK) and stores it on the configured key management servers. The command fails if the configured key management servers are already storing more than 128 AKs. If command fails due to more than 128 keys in cluster, delete unused keys on your key management servers and try the command again. This command is not supported when onboard key management is enabled.

Parameters

[-key-tag <text>] - Key Tag
This parameter specifies the key tag that you want to associate with the new authentication key (AK). The default value is the node name. This parameter can be used to help identify created authentication keys (AKs). For example, the key-manager query command key-tag parameter can be used to query for a specific key-tag value.

[-prompt-for-key {true|false}] - Prompt for Authentication Passphrase
If you specify this parameter as true, the command prompts you to enter an authentication passphrase manually instead of generating it automatically. For security reasons, the authentication passphrase you entered is not displayed at the command prompt. You must enter the authentication passphrase a second time for verification. To avoid errors, copy and paste authentication passphrases electronically instead of entering them manually. Data ONTAP saves the resulting authentication key/key ID pair automatically on the configured key management servers.

Examples

cluster1::> security key-manager create-key -key-tag cluster1
(security key-manager create-key)
Verifying requirements...

Node: cluster1
Creating authentication key...
Authentication key creation successful.
Key ID: F1CB30AFF1CB30B00101000000000000CF0EFD81EA9F6324EA97B369351C56AC

Node: cluster1
Key manager restore operation initialized.
Successfully restored key information.

Node: cluster2
Key manager restore operation initialized.
Successfully restored key information.

cluster1::> security key-manager create-key -key-tag cluster1 -prompt-for-key true
(security key-manager create-key)
Verifying requirements...

Enter a new passphrase:
Reenter the new passphrase:

Node: cluster1
Creating authentication key...
Authentication key creation successful.
Key ID: 6FB176106FB1B719010100000000009FFC077FEEDE8188542230E0B73D289B

Node: cluster1
Key manager restore operation initialized.
Successfully restored key information.

Node: cluster2
Key manager restore operation initialized.
Successfully restored key information.

security key-manager delete
Delete a key management server

Availability: This command is available to cluster administrators at the admin privilege level.

Description
This command removes the key management server at the indicated IP address from list of four possible active key management servers. Before you delete a key management server, you must ensure that this key management server is not the sole storage location for authentication keys that might be needed by self encrypting drives (SEDs). If you neglect to do so, you will no longer be able to access data on affected SEDs. This command is not supported when onboard key management is enabled.

Parameters
-address <IP Address> - Key Manager IP Address
  This parameter specifies the IP address of the key management server you want to remove from use.

Examples

cluster1::> security key-manager delete -address 10.233.1.198
(security key-manager delete)

Node: cluster1
Key manager 10.233.1.198 registration will be removed from service.
Key manager registration successfully removed.

Node: cluster2
Key manager 10.233.1.198 registration will be removed from service.
Key manager registration successfully removed.

security key-manager query
Displays the key IDs stored in a key management server and whether restored (present in the node's key table).

Availability: This command is available to cluster administrators at the admin privilege level.

Description
This command displays the key IDs of the authentication keys that are stored on the key management servers. This command does not update the key tables on the node. To refresh the key tables on the nodes with the key management server key tables, use the security key-manager restore command. This command is not supported when onboard key management is enabled.

Parameters
{ [-fields <fieldname>,...] }  
  This parameter specifies the fields that you want to display.
| [-instance ] |
If you specify this parameter, the command displays all available information about key IDs.

|--node {<nodename> | local} | - Node |
This parameter specifies the name of the node that will query the specified key management servers. If parameter is not specified, all nodes will query the specified key management servers.

|--address <IP Address> | - IP Address |
This parameter specifies the IP address of the key management server you want to query.

|--key-tags <text>, ... | - Key Tag |
If you specify this parameter, the command displays only the key IDs associated with the specified key tags.

|--key-ids <text>, ... | - Authentication Key ID |
If you specify this parameter, the command displays only the specified key IDs.

|--restored {yes | no}, ... | - AK/Key ID Pair Present in Node's Key Table? |
This parameter specifies whether the key ID/AK pairs are present in the specified node's internal key table. If you specify "yes" for this parameter the command displays only the key IDs of the authentication keys that are present in the system's internal key table. If you specify "no" for this parameter the command displays only the key IDs of the authentication keys that are not present in the system's internal key table.

|--count <integer> | - AK/Key ID Pair Count |
This parameter specifies the key ID/AK pair count stored in the key management servers. If you specify this parameter the command displays only the key IDs retrieved from the key management servers with the specified number of key ID/AK pairs.

|--key-manager-server-status {available | not-responding | unknown} | - Key Manager Status |
This parameter specifies the connectivity status of the key management server. If you specify this parameter the command displays only the key IDs retrieved from the key management servers with specified status.

### Examples

```bash
cluster1::> security key-manager query
(security key-manager query)

Node: cluster1
Key Manager: 10.233.1.198
Count: 2

<table>
<thead>
<tr>
<th>Key Tag</th>
<th>Key ID</th>
<th>Restored</th>
</tr>
</thead>
<tbody>
<tr>
<td>cluster1</td>
<td>F1CB30AFF1CB30B00101000000000000A68B167F92DD54196297159B5968923C</td>
<td>yes</td>
</tr>
<tr>
<td>cluster2</td>
<td>F1CB30AFF1CB30B00101000000000000CF0EFD81EA9F6324EA97B369351C56AC</td>
<td>yes</td>
</tr>
</tbody>
</table>

Node: cluster2
Key Manager: 10.233.1.198
Count: 2

<table>
<thead>
<tr>
<th>Key Tag</th>
<th>Key ID</th>
<th>Restored</th>
</tr>
</thead>
<tbody>
<tr>
<td>cluster2</td>
<td>F1CB30AFF1CB30B00101000000000000A68B167F92DD54196297159B5968923C</td>
<td>yes</td>
</tr>
<tr>
<td>cluster1</td>
<td>F1CB30AFF1CB30B00101000000000000CF0EFD81EA9F6324EA97B369351C56AC</td>
<td>yes</td>
</tr>
</tbody>
</table>
```

```bash
cluster1::> security key-manager query -address 10.233.1.198 -node cluster1 -key-tag cluster1
(security key-manager query)

Node: cluster1
Key Manager: 10.233.1.198
Count: 1
```

security key-manager commands 411
Related references

*security key-manager restore* on page 412

**security key-manager restore**

Restore the authentication key and key ID pairs from the key management servers.

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**

This command retrieves and restores all authentication keys (AKs) and key IDs associated with the storage controller from the specified key management servers. This command is not supported when onboard key management is enabled.

**Parameters**

```
[-fields <fieldname>, ...]
```

This parameter specifies the fields that you want to display.

```
[-instance]
```

If you specify this parameter, the command displays information about all entries.

```
[-node <nodename> | local] - Node
```

This parameter specifies the name of the node that is to load the AK/key IDs into its internal key table. If not specified, all nodes retrieve AK/key IDs into their internal key table.

```
[-address <IP Address>] - IP Address
```

If you specify this parameter, the command restores only from key management server at the specified IP address. If not specified the command restores from all available key management servers.

```
[-key-tag <text>] - Key Tag
```

This parameter specifies the value associated with the AK/key ID pair at the time of their creation. If specified, restore only AK/key ID pairs associated with the specified key tag. If not specified, all AK/key ID pairs for the cluster are retrieved.

```
[-key-ids <text>, ...] - Authentication Key ID
```

If you specify this parameter, the command displays only the specified key IDs.

```
[-count <integer>] - AK/Key ID Pair Count
```

This parameter specifies the key ID/AK pair count stored in the key management servers. If you specify this parameter the command displays only the key IDs retrieved from the key management servers with the specified number of key ID/AK pairs.

```
[-key-manager-server-status {available|not-responding|unknown}] - Key Manager Status
```

This parameter specifies the connectivity status of the key management server. If you specify this parameter the command displays only the key IDs retrieved from key management servers with specified status.

**Examples**

```
cluster1::> security key-manager restore
(security key-manager restore)
Node: cluster1
Key Manager: 10.233.1.198
Count: 2
```

412  Commands: Manual Page Reference
security key-manager setup

Configure key manager connectivity

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The security key-manager setup command provides a way to configure key management. Data ONTAP supports two mutually exclusive key management methods: external via one or more key management and interoperability protocol (KMIP) servers, or internal via an onboard key manager. This command is used to configure an external or internal key manager. When configuring an external key management server, this command creates the association between key management servers and the selected node, establishing boot-time parameters used during the boot process to retrieve the authentication keys, and for server communication in the other key-manager operations. For onboard key management, this command prompts you to configure a passphrase to protect internal keys in encrypted form.

This command can also be used to refresh keys that are missing. If this is necessary, you will be prompted to run this command by the security key-manager key show command.

Parameters

[-node <nodename>] · Node Name

When configuring an external key management server, this parameter is used to specify the node that will be used to communicate with the external KMIP server. For onboard key management, this parameter is ignored during the initial configuration of the feature. It is only used when a refresh operation is required (see command description). In either case, if you do not specify a node name, the default is the local node.

Examples

The following example creates a configuration for external key management using IPv4 addresses.
cluster1::> security key-manager setup
Welcome to the key manager setup wizard, which will lead you through
the steps to add boot information.

Enter the following commands at any time
"help" or "?" if you want to have a question clarified,
"back" if you want to change your answers to previous questions, and
"exit" if you want to quit the key manager setup wizard. Any changes
you made before typing "exit" will be applied.

Restart the key manager setup wizard with "security key-manager setup". To accept a default
or omit a question, do not enter a value.

Would you like to configure onboard key management? {yes, no} [yes]: no
Would you like to configure the KMIP server environment? {yes, no} [yes]: yes

You will now be prompted for a subset of your network configuration
setup. These parameters will define a pre-boot network environment,
allowing secure connections to the registered key server.

Enter the TCP port number for KMIP server [5696]:
Enter the network interface [e0c]:
Would you like to configure an IPv4 address? {yes, no} [yes]:
Enter the IP address [10.63.55.148]:
Enter the netmask [255.255.192.0]:
Enter the gateway [10.63.0.1]:
Would you like to configure an IPv6 address? {yes, no} [no]:

The following example creates a configuration for external key management using RFC 5952 supported IPv6 addresses.

cluster1::> security key-manager setup -node cluster1
Welcome to the key manager setup wizard, which will lead you through
the steps to add boot information.

Enter the following commands at any time
"help" or "?" if you want to have a question clarified,
"back" if you want to change your answers to previous questions, and
"exit" if you want to quit the key manager setup wizard. Any changes
you made before typing "exit" will be applied.

Restart the key manager setup wizard with "security key-manager setup". To accept a default
or omit a question, do not enter a value.

Would you like to configure onboard key management? {yes, no} [yes]: no
Would you like to configure the KMIP server environment? {yes, no} [yes]: yes

You will now be prompted for a subset of your network configuration
setup. These parameters will define a pre-boot network environment,
allowing secure connections to the registered key server.

Enter the TCP port number for KMIP server [5696]:
Enter the network interface [e0c]:
Would you like to configure an IPv4 address? {yes, no} [yes]:
Enter the IP address [10.63.55.148]:
Enter the netmask [255.255.192.0]:
Enter the gateway [10.63.0.1]:
Would you like to configure an IPv6 address? {yes, no} [no]:

Enter the IPV6 address: fd20:8b1e:b255:208:250:56ff:fe2a:206
Enter the IPv6 address prefix length [64]:
Enter the IPv6 gateway: fd20:8b1e:b255:208:250:56ff:fe2a:200

The following example creates a configuration for onboard key management.

cluster1::> security key-manager setup
Welcome to the key manager setup wizard, which will lead you through
the steps to add boot information.

Enter the following commands at any time
"help" or "?" if you want to have a question clarified,
"back" if you want to change your answers to previous questions, and
"exit" if you want to quit the key manager setup wizard. Any changes
You made before typing "exit" will be applied.

Restart the key manager setup wizard with "security key-manager setup". To accept a default or omit a question, do not enter a value.

Would you like to configure onboard key management? {yes, no} [yes]:

Enter the cluster-wide passphrase for onboard key management. This passphrase cannot be reconfigured. To continue the configuration, enter the passphrase, otherwise type "exit": [enter a passphrase of 32 to 256 char long]

Re-enter the cluster-wide passphrase:
Warning: Once passphrase for onboard key management is set, it cannot be reconfigured. Would you like to continue? {yes, no} [no]: yes

After configuring onboard key management, save the encrypted configuration data in a safe location so that you can use it if you need to perform a manual recovery operation. To view the data, use the "security key-manager backup show" command.

security key-manager key show on page 417

security key-manager show

Display key management servers

Availability: This command is available to cluster administrators at the admin privilege level.

Description
This command displays the key management servers configured on the cluster. This command is not supported when onboard key management is enabled.

Parameters

[-fields <fieldname>,...]
This specifies the fields that need to be displayed.

[-status ]
If you specify this parameter, the command displays the status of each key management server.

[-instance ]]
If you specify this parameter, the command displays information about all entries.

[-node {<nodename>|local}] - Node
This parameter specifies the name of the node that you want to retrieve key management server status for. If parameter is not specified, all nodes will retrieve the key management servers status.

[-address <IP Address>] - Key Manager IP Address
Shows only a key management server registered with the input address. It is also possible to show multiple key management servers.

Examples

cluster1::> security key-manager show -address 10.233.1.198 -status -node cluster1

<table>
<thead>
<tr>
<th>Node</th>
<th>Registered Key Manager</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>cluster1</td>
<td>10.233.1.198</td>
<td>available</td>
</tr>
<tr>
<td>cluster2</td>
<td>10.233.1.198</td>
<td>available</td>
</tr>
</tbody>
</table>
**security key-manager certificate commands**

The certificate directory

**security key-manager certificate update**

Update key manager SSL certificates

*Availability:* This command is available to cluster administrators at the *admin* privilege level.

**Description**

This command updates an SSL/TLS certificate in-place without requiring the original SSL/TLS certificate to be deleted. This command is not supported when onboard key management is enabled.

**Parameters**

- `-type {client|server}` - SSL Certificate Type
  
  This parameter is either "client" or "server". If "client", the internal client certificate is replaced. If "server", the internal server certificate is replaced.

- `[<-address <IP Address>]]` - Key Manager IP Address
  
  This parameter updates the key manager server certificate for a particular key management server at the given IP address.

**Examples**

The following example is for updating a server certificate.

```
cluster1::> security key-manager certificate update -type server -address 10.232.186.8

Node: cluster1
Key manager 10.232.186.8 certificate-authority certificate will be updated.
Update successful.

Node: cluster2
Key manager 10.232.186.8 certificate-authority certificate will be updated.
Update successful.
```

The following example is for updating a client certificate.

```
cluster1::> security key-manager certificate update -type client

Node: cluster1
The system client certificate registered with key manager will be updated.
Update successful.

Node: cluster2
The system client certificate registered with key manager will be updated.
Update successful.
```

**security key-manager backup commands**

The backup directory
security key-manager backup show

Show salt and wrapped keys as a hex dump

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**
This command displays the backup information for onboard key management, which would be used to recover the cluster in case of catastrophic situations. The information displayed is for the cluster as a whole (not individual nodes). This command is not supported for an external key management configuration.

**Examples**

```
cluster1::> security key-manager backup show
BEGIN BACKUP
TmV0QXBwIEtleSBCbG9iAAEAAAAAeCAEAAAAAAADuD+byAAAAACEAAAAAAAQAABvOlH0AAAAAMh7qDLryH1DBz12piVdy9ATSEMT0COT1yFs4PDjTaVdZyKldIPhLXAWJoIyg58q8yY1SEBqml1WgE5DLRqkiAAAACACgAAAAAAA3Wh7gAAAAAAAIAAAAAgAZJE1Wdv6r5RCAVhGcL0+wAAAAAAAG.png
```

security key-manager key commands

The key directory

security key-manager key show

Display Encryption Key IDs

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**
This command displays the key IDs of all the keys that are available in onboard key management. This command is not supported for an external key management configuration.
Parameters

{[-fields <fieldname>,...]
    If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use `-fields ?' to display the fields to specify.

|[-detail ]
    If this parameter is specified, the command displays additional details about the key IDs.

|[-instance ]
    If you specify the -instance parameter, the command displays detailed information about all fields.

[-node {<nodename>|local}] - Node
    If this parameter is specified, the command displays information only about key IDs that are located on the specified storage system.

[-key-store <Key Store>] - Key Store
    If this parameter is specified, the command displays information only about key IDs that are managed by the specified key management. For example, use onboard for local key management or external for key management and interoperability protocol (KMIP) server.

[-key-id <text>] - Key Identifier
    If this parameter is specified, the command displays information only about the specified key IDs.

[-key-tag <text>] - Key Tag
    If this parameter is specified, the command displays information only about key IDs that have the specified key tags.

[-key-location <text>] - Key Location
    If this parameter is specified, the command displays information only about key IDs that are located on the specified key location. For example, use IP address of KMIP server.

[-used-by <Key Usage Type>] - Used By
    If this parameter is specified, the command displays information only about key IDs that are associated with the specified application usage of the keys. For example, "NSE-AK" would display key IDs only for NSE drives.

[-restored {yes|no}] - Restored
    If this parameter is specified, the command displays information only about key IDs that have the specified value of restored keys. If restored is yes, then the corresponding key is available (normal). If restored is no, use the security key-manager setup command to restore the key. See the man page for security key-manager setup for details.

Examples

cluster1::> security key-manager key show

Node: node1
Key Store: onboard
Key ID
--------------------------------------------------------------------------------
000000000000000002000000000001001BC4C708E2A89A312E14B6CE6D4D49D4
000000000000000002000000000001005E89099721F88176E6E3AE8B68BE1BFCA

Node: node2
Key Store: onboard
Key ID
--------------------------------------------------------------------------------
000000000000000002000000000001001BC4C708E2A89A312E14B6CE6D4D49D4
000000000000000002000000000001005E89099721F88176E6E3AE8B68BE1BFCA
4 entries were displayed.

cluster1::> security key-manager key show -detail

- `security key-manager setup` on page 413

security login commands

Manage login methods, roles, and passwords

security login create

Add a login method

**Availability:** This command is available to cluster administrators at the `admin` privilege level.

**Description**

The `security login create` command creates a login method for the management utility. A login method consists of a user name, an application (access method), and an authentication method. A user name can be associated with multiple applications. It can optionally include an access-control role name. If an Active Directory, LDAP, or NIS group name is used, then the login method gives access to users belonging to the specified group. If the user is a member of multiple groups provisioned in the security login table, then the user will get access to a combined list of the commands authorized for the individual groups.

**Parameters**

- `-vserver <Vserver Name>` - Vserver

  This specifies the Vserver name of the login method.

- `-user-or-group-name <text>` - User Name or Group Name

  This specifies the user name or Active Directory, LDAP, or NIS group name of the login method. The Active Directory, LDAP, or NIS group name can be specified only with the `domain` or `nsswitch` authentication method and `ontapi` and `ssh` application. If the user is a member of multiple groups provisioned in the security login table, then the user will get access to a combined list of the commands authorized for the individual groups.

- `-application <text>` - Application

  This specifies the application of the login method. Possible values include console, http, ontapi, rsh, snmp, service-processor, ssh, and telnet.

  Setting this parameter to `service-processor` grants the user access to the Service Processor (SP). Because the SP supports only password authentication, when you set this parameter to `service-processor`, you must also set the `-authentication-method` parameter to `password`. Vserver user accounts cannot access the SP. Therefore, you cannot use the `-vserver` parameter when you set this parameter to `service-processor`. 
-authentication-method <text> - Authentication Method

This specifies the authentication method of the login method. Possible values include the following:

- cert - SSL certificate authentication
- community - SNMP community strings
- domain - Active Directory authentication
- nsswitch - LDAP or NIS authentication
- password - Password
- publickey - Public-key authentication
- usm - SNMP user security model

-role <text> - Role Name

This specifies an access-control role name for the login method.

[-comment <text>] - Comment Text

This specifies comment text for the user account, for example, "Guest account". The maximum length is 128 characters.

[-is-ns-switch-group (yes|no)] - Whether Ns-switch Group

This specifies whether user-or-group-name is an LDAP or NIS group. Possible values are yes or no. Default value is no.

Examples

The following example illustrates how to create a login that has the user name monitor, the application ssh, the authentication method password, and the access-control role guest for Vserver vs:

```
cluster1::> security login create -vserver vs -user-or-group-name monitor -application ssh -
authentication-method password -role guest
```

The following example illustrates how to create a login that has the user name monitor, the application ontapi, the authentication method password, and the access-control role vsadmin for Vserver vs:

```
cluster1::> security login create -vserver vs -user-or-group-name monitor -application ontapi -
authentication-method password -role vsadmin
```

The following example illustrates how to create a login that has the user name monitor, the application ssh, the authentication method publickey, and the access-control role guest for Vserver vs:

```
cluster1::> security login create -vserver vs -user-or-group-name monitor -application ssh -
authentication-method publickey -role guest
```

The following example illustrates how to create a login that has the user name monitor, the application http, the authentication method cert, and the access-control role admin for Vserver vs:

```
cluster1::> security login create -vserver vs -user-or-group-name monitor -application http -
authentication-method cert -role admin
```

The following example illustrates how to create a login that has the Active Directory group name adgroup in DOMAIN1, the application ssh, the authentication method domain, and the access-control role vsadmin for Vserver vs:

```
cluster1::> security login create -vserver vs -user-or-group-name DOMAIN1\adgroup -application ssh -
authentication-method domain -role vsadmin
```
The following example illustrates how to create a login that has a group name `nssgroup` in the LDAP or NIS server, the application `ontapi`, the authentication method `nsswitch`, and the access-control role `vsadmin` for Vserver `vs`. Here `is-ns-switch-group` must be set to `yes`:

```
cluster1::> security login create -vserver vs -user-or-group-name nssgroup -application ontapi -
    authentication-method nsswitch -role vsadmin -is-ns-switch-group yes
```

**security login delete**

Delete a login method

**Availability:** This command is available to `cluster` administrators at the `admin` privilege level.

**Description**
The `security login delete` command deletes a login method.

**Parameters**
- `-vserver <Vserver Name>` - Vserver
  This optionally specifies the Vserver name of the login method.
- `-user-or-group-name <text>` - User Name or Group Name
  This specifies the user name or Active Directory, LDAP, or NIS group name of the login method that is to be deleted. A user name can be associated with multiple applications.
- `-application <text>` - Application
  This specifies the application of the login method. Possible values include console, http, ontapi, rsh, snmp, service-processor, ssh, and telnet.
- `-authentication-method <text>` - Authentication Method
  This specifies the authentication method of the login method. Possible values include the following:
  - cert - SSL certificate authentication
  - community - SNMP community strings
  - domain - Active Directory authentication
  - nsswitch - LDAP or NIS authentication
  - password - Password
  - pubkey - Public-key authentication
  - usm - SNMP user security model

**Examples**
The following example illustrates how to delete a login that has the username `guest`, the application `ssh`, and the authentication method `password` for Vserver `vs`:

```
cluster1::> security login delete -user-or-group-name guest -application ssh -authentication-
    method password -vserver vs
```

The following example illustrates how to delete a login that has the username `guest`, the application `ontapi`, and the authentication method `cert` for Vserver `vs`:

```
```
security login expire-password

Expire user's password

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The security login expire-password command expires a specified user account password, forcing the user to change the password upon next login.

Parameters
-vserver <Vserver Name> - Vserver
This optionally specifies the Vserver to which the user account belongs.

-username <text> - Username
This specifies the user name of the account whose password you want to expire.

[-hash-function {sha512|sha256}] - Password Hash Function
This optionally specifies the password-hashing algorithm used for encrypting the passwords that you want to expire. The supported values include are as follows:
  • sha512 - Secure hash algorithm (512 bits)
  • sha256 - Secure hash algorithm (256 bits)
  • md5 - Message digest algorithm (128 bits)

[-lock-after <integer>] - Lock User Account After N days (privilege: advanced)
This optionally specifies the number of days after which the new password hash policy will be enforced. The enforcement will lock all user accounts that are still compliant with the provided hash algorithm using -hash-function parameter.

Examples
The following command expires the password of the 'jdoe' user account which belongs to the 'vs1' Vserver.

    cluster1::> security login expire-password -vserver vs1 -username jdoe

The following command expires all user account passwords that are encrypted with the MD5 hash function.

    cluster1::> security login expire-password -vserver * -username * -hash-function md5
The following command expires the password of any Vserver's user account named 'jdoe' that is encrypted with the MD5 hash function.

```
cluster1::> security login expire-password -vserver * -username jdoe -hash-function md5
```

The following command expires the password of the 'vs1' Vserver user account named 'jdoe' that is encrypted with the MD5 hash function.

```
cluster1::> security login expire-password -vserver vs1 -username jdoe -hash-function md5
```

The following command expires all user account passwords that are encrypted with the MD5 hash function and enforce the new password hash policy after 180 days.

```
cluster1::> security login expire-password -vserver * -username * -hash-function md5 -lock-after 180
```

**security login lock**

Lock a user account with password authentication method

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**
The `security login lock` command locks a specified account, preventing it from accessing the management interface.

**Parameters**
- **-vserver <Vserver Name>** - Vserver
  - This optionally specifies the Vserver to which the user account belongs.
- **-username <text>** - Username
  - This specifies the user name of the account that is to be locked.

**Examples**
The following example locks a user account named 'jdoe' which belongs to the Vserver 'vs1'.

```
cluster1::> security login lock -vserver vs1 -username jdoe
```

**security login modify**

Modify a login method

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**
The `security login modify` command modifies the access-control role name of a login method. If the user is a member of multiple groups provisioned in the security login table, then the user will get access to a combined list of the commands authorized for the individual groups.

**Parameters**
- **-vserver <Vserver Name>** - Vserver
  - This specifies the Vserver name of the login method.
- `user-or-group-name <text>` - User Name or Group Name
  This specifies the user name, Active Directory, LDAP, or NIS group name of the login method that is to be modified. A user name can be associated with multiple applications. If the user is a member of multiple groups provisioned in the security login table, then the user will get access to a combined list of the commands authorized for the individual groups.

- `application <text>` - Application
  This specifies the application of the login method. Possible values include console, http, ontapi, rsh, snmp, service-processor, ssh, and telnet.

- `authentication-method <text>` - Authentication Method
  This specifies the authentication method of the login method. Possible values include the following:
  - `cert` - SSL certificate authentication
  - `community` - SNMP community strings
  - `domain` - Active Directory authentication
  - `nsswitch` - LDAP or NIS authentication
  - `password` - Password
  - `publickey` - Public-key authentication
  - `usm` - SNMP user security model

- `[-role <text>]` - Role Name
  This modifies the access-control role name for the login method.

- `[-comment <text>]` - Comment Text
  This specifies comment text for the user account, for example, "Guest account". The maximum length is 128 characters.

- `[-is-ns-switch-group {yes|no}]` - Whether Ns-switch Group
  This specifies if `user-or-group-name` is an LDAP or NIS group. Possible values are yes or no. Default value is no.

### Examples

The following example illustrates how to modify a login method that has the user name `guest`, the application `ontapi`, and the authentication method `password` to use the access-control role `guest` for Vserver `vs`:

```
cluster1::> security login modify -user-or-group-name guest -application ontapi -authentication-method password -role guest -vserver vs
```

The following example illustrates how to modify a login method that has the user name `guest`, the application `ssh`, and the authentication method `publickey` to use the access-control role `vsadmin` for Vserver `vs`:

```
cluster1::> security login modify -user-or-group-name guest -application ssh -authentication-method publickey -role vsadmin -vserver vs
```

The following example illustrates how to modify a login method that has the group name `nssgroup`, the application `ontapi`, and the authentication method `nsswitch` to use the access-control role `readonly` for Vserver `vs`. Here `is-ns-switch-group` must be set to `yes`:

```
cluster1::> security login modify -user-or-group-name nssgroup -application ontapi -authentication-method nsswitch -role readonly -vserver vs -is-ns-switch-group yes
```
security login password

Modify a password for a user

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The security login password command resets the password for a specified user. The command prompts you for the user's old and new password.

Parameters
-vserver <Vserver Name> - Vserver
This optionally specifies the Vserver name of the login method.

-username <text> - Username
This optionally specifies the user name whose password is to be changed. If you do not specify a user, the command defaults to the user name you are currently using.

Examples
The following command initiates a password change for the 'admin' user account of the 'vs' Vserver.

```
cluster1::> security login password -username admin -vserver vs
```

The following command initiates a password change for the 'vs' Vserver user account named 'admin'. The new password will be encrypted by using the SHA512 password-hashing algorithm.

```
cluster1::*> security login password -username admin -vserver vs -hash-function sha512
```

The following command initiates a password change for the 'vs' Vserver user account named 'admin'. The new password will be encrypted by using the SHA256 password-hashing encryption algorithm.

```
cluster1::*> security login password -username admin -vserver vs -hash-function sha256
```

security login password-prepare-to-downgrade

Reset password features introduced in the Data ONTAP version

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
If the password of the system administrator is not encrypted with an encryption type supported by releases earlier than ONTAP 9.0, this command prompts the administrator for a new password and encrypt it using a supported encryption type on each cluster or at each site in a MetroCluster configuration. In a MetroCluster configuration, this command must be run on both sites. The password for all other users are marked as "expired". This causes them to be re-encrypted using a compatible encryption type. The expired passwords are changed with an internally generated password. The administrator must change the passwords for all users before the users can login. The users are prompted to change their password upon login. This command disables the logging of unsuccessful login attempts. The command must be run by a user with the cluster admin role from a clustershell session on the console device. This user must be unlocked. If you fail to run this command, the revert process fails.

Parameters
-disable-feature-set <downgrade version> - Data ONTAP Version
This parameter specifies the Data ONTAP version that introduced the password feature set.
Examples
The following command disables the logging of unsuccessful login attempts.

```
cluster1::*> security login password prepare-to-downgrade -disable-feature-set 8.3.1
Warning: This command will disable the MOTD feature that prints unsuccessful login attempts.
Do you want to continue? {y|n}: y
```

The following command prompts system administrator to enter password and encrypt it with the hashing algorithm supported by releases earlier than Data ONTAP 9.0.

```
cluster1::*> security login password prepare-to-downgrade -disable-feature-set 9.0.0
Warning: If your password is not encrypted with an encryption type supported by releases earlier than Data ONTAP 9.0.0, this command will prompt you for a new password and encrypt it using a supported encryption type on each cluster or at each site in a MetroCluster configuration. In a MetroCluster configuration, this command must be run on both sites. The password for all other users are marked as "expired" and changed to an internally generated password. The administrator must change the passwords for all users before the users can login. The users are prompted to change their password upon login.
Do you want to continue? {y|n}:
Enter a new password:
Enter it again:
```

security login show
Show user login methods

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The security login show command displays the following information about user login methods:

- User name
- Application (console, http, ontapi, rsh, snmp, service-processor, ssh, or telnet)
- Authentication method (community, password, publickey, or usm)
- Role name
- Whether the account is locked
- Whether the user name refers to nsswitch group
- Password hash function

Parameters
`[-fields <fieldname>, ...]`
If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `'-fields ?' to display the fields to specify.
If you specify the -instance parameter, the command displays detailed information about all fields.

- **vserver <Vserver Name>** - Vserver
  Displays the login methods that match the specified Vserver name.

- **user-or-group-name <text>** - User Name or Group Name
  Displays the login methods that match this parameter value. Value can be a user name or Active Directory, LDAP, or NIS group name.

- **application <text>** - Application
  Displays the login methods that match the specified application type. Possible values include console, http, ontapi, rsh, snmp, service-processor, ssh, and telnet.

- **authentication-method <text>** - Authentication Method
  Displays the login methods that match the specified authentication method. Possible values include the following:
  
  - cert - SSL certificate authentication
  - community - SNMP community strings
  - domain - Active Directory authentication
  - nsswitch - LDAP or NIS authentication
  - password - Password
  - publickey - Public-key authentication
  - usm - SNMP user security model

- **role <text>** - Role Name
  Displays the login methods that match the specified role.

- **is-account-locked {yes|no}** - Account Locked
  Displays the login methods that match the specified account lock status.

- **comment <text>** - Comment Text
  Displays the login methods that match the specified comment text.

- **is-ns-switch-group {yes|no}** - Whether Ns-switch Group
  This specifies whether user-or-group-name is an LDAP or NIS group. Possible values are yes or no.

- **hash-function {sha512|sha256}** - Password Hash Function (privilege: advanced)
  Displays the login methods that match the specified password-hashing algorithm. Possible values are:
  
  - sha512 - Secure hash algorithm (512 bits)
  - sha256 - Secure hash algorithm (256 bits)
  - md5 - Message digest algorithm (128 bits)

### Examples
The example below illustrates how to display information about all user login methods:

```
cluster1::> security login show
```

<table>
<thead>
<tr>
<th>Vserver: cluster1</th>
<th>Authentication</th>
<th>Acct</th>
<th>Is-Nsswitch</th>
</tr>
</thead>
<tbody>
<tr>
<td>User/Group Name</td>
<td>Application</td>
<td>Method</td>
<td>Role Name</td>
</tr>
</tbody>
</table>

## security login commands
security login unlock

Unlock a user account with password authentication method

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**
The security login unlock command unlocks a specified account, enabling it to access the management interface.

**Parameters**

- `-vserver <Vserver Name>` - Vserver
  
  This optionally specifies the Vserver to which the user account belongs.

- `-username <text>` - Username
  
  This specifies the user name of the account that is to be unlocked.

**Examples**
The following command unlocks a user account named jdoe which belongs to the Vserver vs1.

```
cluster1::> security login unlock -vserver vs1 -username jdoe
```

security login whoami

Show the current user and role of this session

**Availability:** This command is available to cluster and Vserver administrators at the admin privilege level.

**Description**
The security login whoami command displays the name and role of the user logged in at the current console session. It takes no options or other parameters.

**Examples**
The following example shows that the current session is logged in by using the 'admin' user account:

security login domain-tunnel commands

The domain-tunnel directory

security login domain-tunnel create

Add authentication tunnel Vserver for administrative Vserver

Availability: This command is available to cluster administrators at the admin privilege level.

Description

This command establishes a gateway (tunnel) for authenticating Windows Active Directory (AD) domain users' access to the cluster.

Before using this command to establish the tunnel, the following must take place:

- You must use the security login create command to create one or more AD domain user accounts that will be granted access to the cluster.
  - The -authmethod parameter of the security login create command must be set to 'domain'.
  - The -username parameter of the security login create command must be set to a valid AD domain user account that is defined in a Windows Domain Controller's Active Directory. The user account must be specified in the format of <domainname>\<username>, where "domainname" is the name of the CIFS domain server.
- You must identify or create a CIFS-enabled data Vserver that will be used for Windows authentication with the Active Directory server. This Vserver is the tunnel Vserver, and it must be running for this command to succeed.

Only one Vserver can be used as the tunnel. If you attempt to specify more than one Vserver for the tunnel, Data ONTAP returns an error. If the tunnel Vserver is stopped or deleted, AD domain users' authentication requests to the cluster will fail.

Parameters

-vserver <vserver>  - Authentication Tunnel Vserver

This parameter specifies a data Vserver that has been configured with CIFS. This Vserver will be used as the tunnel for authenticating AD domain users' access to the cluster.

Examples

The following commands create an Active Directory domain user account ('DOMAIN1\Administrator') for the 'cluster1' cluster, create a data Vserver ('vs'), create a CIFS server ('vscifs') for the Vserver, and specify 'vs' as the tunnel for authenticating the domain user access to the cluster.

```
cluster1::> security login create -vserver cluster1 -username DOMAIN1\Administrator -application ssh -authmethod domain -role admin
cluster1::> vserver create -vserver vs -rootvolume vol -aggregate aggr -rootvolume-style mixed
```
Related references

security login create on page 419
vserver create on page 1395
vserver cifs create on page 1427

security login domain-tunnel delete
Delete authentication tunnel Vserver for administrative Vserver

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The security login domain-tunnel delete command deletes the tunnel established by the security login domain-tunnel create command. An error message will be generated if no tunnel exists.

Examples
The following command deletes the tunnel established by security login domain-tunnel create.

```
cluster1::> security login domain-tunnel delete
```

Related references

security login domain-tunnel create on page 429

security login domain-tunnel modify
Modify authentication tunnel Vserver for administrative Vserver

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The security login domain-tunnel modify command modifies or replaces the tunnel Vserver. If a tunnel Vserver is not already specified, it sets the current tunnel Vserver with this Vserver, otherwise, it replaces the current tunnel Vserver with the Vserver that you specify. If the tunnel Vserver is changed, authentication requests via previous Vserver will fail. See security login domain-tunnel create for more information.

Parameters

[-vserver <vserver>] - Authentication Tunnel Vserver
This parameter specifies a Vserver that has been configured with CIFS and is associated with a Windows Domain Controller's Active Directory authentication. This Vserver will be used as an authentication tunnel for login accounts so that they can be used with administrative Vservers.

Examples
The following command modifies the tunnel Vserver for administrative Vserver.

```
cluster1::> security login domain-tunnel modify -vserver vs
```
security login domain-tunnel show

Show authentication tunnel Vserver for administrative Vserver

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The `security login domain-tunnel show` command shows the tunnel Vserver that was specified by the `security login domain-tunnel create` or `security login domain-tunnel modify` command.

Examples
The example below shows the tunnel Vserver, vs, that is currently used as an authentication tunnel. The output informs you that the table is currently empty if tunnel Vserver has not been specified.

```
cluster1:/> security login domain-tunnel show
Tunnel Vserver: vs
```

SSH login banner

Manage the login banner

The SSH login banner management commands.

security login banner modify

Modify the login banner message

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The `security login banner modify` command modifies the login banner. The login banner is printed just before the authentication step during the SSH and console device login process.

Parameters

- `vserver <Vserver Name>` - Vserver Name
  Use this parameter to specify the Vserver whose banner will be modified. Use the name of the cluster admin Vserver to modify the cluster-level message. The cluster-level message is used as the default for data Vservers that do not have a message defined.

- `{ [-message <text>] } - Login Banner Message
  This optional parameter can be used to specify a login banner message. If the cluster has a login banner message set, the cluster login banner will be used by all data Vservers as well. Setting a data Vserver's login banner will override the display of the cluster login banner. To reset a data Vserver's login banner to use the cluster login banner, use this parameter with the value "-".

  If you use this parameter, the login banner cannot contain newlines (also known as end of lines (EOLs) or line breaks). To enter a login banner message with newlines, do not specify any parameter. You will be prompted to enter the message interactively. Messages entered interactively can contain newlines.
Non-ASCII characters must be provided as Unicode UTF-8.

Use this parameter to specify the URI from where the login banner will be downloaded. Note that the message must not exceed 2048 bytes in length. Non-ASCII characters must be provided as Unicode UTF-8.

Examples
This example shows how to enter a login banner interactively:

```
cluster1::> security login banner modify
Enter the login banner for Vserver "cluster1".
Max size: 2048. Enter a blank line to terminate input. Press Ctrl-C to abort.
0 1 2 3 4 5 6 7 8
1234567890123456789012345678901234567890123456789012345678901234567890
Authorized users only!

cluster1::>
```

security login banner show

Display the login banner message

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The security login banner show command displays the login banner.

Parameters
[-fields <fieldname>, ...]

If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

[-instance]

If you specify the -instance parameter, the command displays detailed information about all fields.

[-vserver <Vserver Name>] - Vserver Name

Selects login banners that match the specified value. Use the name of the admin Vserver to specify the cluster-level login banner.

[-message <text>] - Login Banner Message

Selects login banners that match the specified value. By default, this command will not display unconfigured, or empty, login banners. To display all banners, specify -message *.

Examples
The following shows sample output from this command:

```
cluster1::> security login banner show
Message
-----------------------------------------------------------------
Authorized users only!

cluster1::>
```
security login ns-switch commands

The ns-switch directory

security login ns-switch group-authentication commands

The group-authentication directory

security login ns-switch group-authentication prepare-to-downgrade

Remove Ns-switch Groups for Downgrade

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
The security login ns-switch group-authentication prepare-to-downgrade command disables the support for group authentication and role merge features in releases earlier than ONTAP 9.0.

Examples
The following command disables ns-switch group-authentication feature:

```
cluster1:*> security login ns-switch group-authentication prepare-to-downgrade
```

security login motd commands

Manage the message of the day (MOTD)
Manage the clustershell message of the day (MOTD).

security login motd modify

Modify the message of the day

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The security login motd modify command updates the message of the day (MOTD).

There are two categories of MOTDs: the cluster-level MOTD and the data Vserver-level MOTD. A user logging in to a data Vserver's clustershell will potentially see two messages: the cluster-level MOTD followed by the Vserver-level MOTD for that Vserver. The cluster administrator can enable or disable the cluster-level MOTD on a per-Vserver basis. If the cluster administrator disables the cluster-level MOTD for a Vserver, a user logging into the Vserver will not see the cluster-level message. Only a cluster administrator can enable or disable the cluster-level message.

Parameters
- `-vserver <Vserver Name>` - Vserver Name
  
  Use this parameter to specify the Vserver whose MOTD will be modified. Use the name of the cluster admin Vserver to modify the cluster-level message.

- `[-message <text>]` - Message of the Day (MOTD)

  This optional parameter can be used to specify a message. If you use this parameter, the MOTD cannot contain newlines (also known as end of lines (EOLs) or line breaks). If you do not specify any parameter other than the `-vserver` parameter, you will be prompted to enter the message interactively. Messages entered interactively can contain newlines. Non-ASCII characters must be provided as Unicode UTF-8.

  The message may contain dynamically generated content using the following escape sequences:
- A single backslash character.
- \b - No output: supported for compatibility with Linux only.
- \c - Cluster name.
- \d - Current date as set on the login node.
- \t - Current time as set on the login node.
- \i - Incoming LIF IP address (prints 'console' for a console login).
- \l - Login device name (prints 'console' for a console login).
- \L - Last login for the user on any node in the cluster.
- \m - Machine architecture.
- \n - Node or data Vserver name.
- \N - Name of user logging in.
- \o - Same as \O. Provided for Linux compatibility.
- \O - DNS domain name of the node. Note that the output is dependent on the network configuration and may be empty.
- \r - Software release number.
- \s - Operating system name.
- \u - Number of active clustershell sessions on the local node. For the cluster admin: all clustershell users. For the data Vserver admin: only active sessions for that data Vserver.
- \U - Same as \u, but has 'user' or 'users' appended.
- \v - Effective cluster version string.
- \w - Active sessions across the cluster for the user logging in ('who').

A backslash followed by any other character is emitted as entered.

```
[-uri \{(ftp:http://(hostname|IPv4 Address|'['IPv6 Address']')...\}] - Download URI for the MOTD
```

Use this parameter to specify the URI from where the message of the day will be downloaded. Note that the message must not exceed 2048 bytes in length. Non-ASCII characters must be provided as Unicode UTF-8.

```
[-is-cluster-message-enabled \{true\false\}] - Is Cluster-level Message Enabled?
```

Use this parameter to enable or disable the display of the cluster-level MOTD for the specified Vserver.

### Examples

This example shows how to enter a MOTD interactively:

```
cluster1::> security login motd modify -vserver vs0
Enter the message of the day for Vserver "vs0".
Max size: 2048. Enter a blank line to terminate input. Press Ctrl-C to abort.
```

```
0 1 2 3 4 5 6 7 8
123456789012345678901234567890123456789012345678901234567890123456789012345678901234567890

```

Welcome to the Vserver!

security login motd show

Display the message of the day

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The security login motd show command displays information about the cluster-level and data Vserver clustershell message of the day (MOTD).

Parameters
{ [-fields <fieldname>, ...]  
  If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use -fields ? to display the fields to specify.

  [-instance]  
  If you specify the -instance parameter, the command displays detailed information about all fields.

  [-vserver <Vserver Name>] - Vserver Name  
  Selects the message of the day entries that match this parameter value. Use the name of the cluster admin Vserver to see the cluster-level MOTD.

  [-message <text>] - Message of the Day (MOTD)  
  Selects the message of the day entries that match this parameter value.

  [-is-cluster-message-enabled (true|false)] - Is Cluster-level Message Enabled?  
  Selects the message of the day entries that match this parameter value.

Examples
The following example displays all message of the day entries:

```
cluster1::> security login motd show
Vserver: cluster1
  Is the Cluster MOTD Displayed?: true
  Message
  The cluster is running normally.
Vserver: vs0
  Is the Cluster MOTD Displayed?: true
  Message
  Welcome to the Vserver!
2 entries were displayed.
```

security login publickey commands

Manage public keys
security login publickey create

Add a new public key

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The security login publickey create associates an existing public key with a user account. This command requires that you enter a valid OpenSSH-formatted public key, a user name, index number, and optionally, a comment.

Parameters

-vserver <Vserver Name> - Vserver
This parameter optionally specifies the Vserver of the user for whom you are adding the public key.

-username <text> - Username
This parameter specifies the name of the user for whom you are adding the public key. If you do not specify a user, the user named admin is specified by default.

[-index <integer>] - Index
This parameter specifies an index number for the public key. The default value is the next available index value, starting with zero if it is the first public key created for the user.

-publickey <certificate> - Public Key
This specifies the OpenSSH public key, which must be enclosed in double quotation marks.

[-comment <text>] - Comment
This optionally specifies comment text for the public key. Note that comment text should be enclosed in quotation marks.

Examples

The following command associates a public key with a user named tsmith for Vserver vs1. The public key is assigned index number 5 and the comment text is “This is a new key”.

```
cluster1::> security login publickey create -vserver vs1 -username tsmith -index 5 -publickey "ssh-rsa AAAAB3NzaC1yc2EAAAABIwAAAIEAspH64CYbUsDQCDW2ZJnK6J /VU9upnKzd2ZzAk9C1f7YaWROAFHsZQe51UmQ3ldi8AD0Vfbr5T6H4FCixNAIza Fc1D7bgnmdj9eN5edGz/JWrfTQbLDh2ybX+72dpQB0cYW8he6eDjIoPLcb ZBgfM1PXh8VjeU44i7W4+s0hG0E=tsmith@publickey.example.com" -comment "This is a new key"
```

security login publickey delete

Delete a public key

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The security login publickey delete command deletes a public key for a specific user. To delete a public key, you must specify a user name and index number.

Parameters

-vserver <Vserver Name> - Vserver
This parameter optionally specifies the Vserver of the user for whom you are adding the public key.
**-username <text> - Username**

This parameter specifies the name of the user for whom you are deleting a public key. If you do not specify a user, the user named admin is specified by default.

**-index <integer> - Index**

This parameter specifies an index number for the public key.

---

**Examples**

The following command deletes the public key for the user named tsmith with the index number 5.

```
cluster1:~> security login publickey delete -username tsmith -index 5
```

---

**security login publickey load-from-uri**

Load one or more public keys from a URI

**Availability:** This command is available to cluster and Vserver administrators at the admin privilege level.

**Description**

The `security login publickey load-from-uri` command loads one or more public keys from a Universal Resource Identifier (URI). To load public keys from a URI, you must specify a user name, the URI from which to load them, and optionally, whether you want to overwrite the existing public keys.

**Parameters**

**-vserver <vserver name> - Vserver**

This parameter optionally specifies the Vserver for the user associated with the public keys.

**-username <text> - Username**

This parameter specifies the username for the public keys. If you do not specify a username, the username “admin” is used by default.

**-uri {(ftp|http):/(hostname|IPv4 Address|['IPv6 Address'])...} - URI to load from**

This parameter specifies the URI from which the public keys will be loaded.

**-overwrite (true|false) - Overwrite Entries**

This parameter optionally specifies whether you want to overwrite existing public keys. The default value for this parameter is `false`. If the value is `true` and you confirm to overwrite, then the existing public keys are overwritten with the new public keys. If you use the value `false` or do not confirm the overwrite, then newly loaded public keys are appended to the list of existing public keys using the next available index.

---

**Examples**

The following command shows how to load public keys for the user named tsmith from the URI ftp://ftp.example.com/identity.pub. This user's existing public keys are not overwritten.

```
```

The following command shows how to load public keys for the user named tsmith from the URI ftp://ftp.example.com/identity.pub. This user's existing public keys are overwritten if user entered the option 'y' or 'Y'. The user's existing public keys are not overwritten if user entered the option 'n' or 'N' and the newly loaded public keys are appended to the list of existing public keys using the next available index. The user and password credentials that you provide when you use this command are the credentials to access the server specified by the URI.
security login publickey modify

Modify a public key

**Availability:** This command is available to **cluster** and **Vserver** administrators at the **admin** privilege level.

**Description**
The `security login publickey modify` command modifies a public key and optionally its comment text.

**Parameters**
- **-vserver** `<Vserver Name>` - Vserver
  Specifies the Vserver for the user associated with the public key.
- **-username** `<text>` - Username
  Specifies the username for the public key. If you do not specify a username, the username 'admin' is used by default.
- **-index** `<integer>` - Index
  Specifies the index number of the public key. The index number of the public key can be found by using the `security login publickey show` command.
- **-publickey** `<certificate>` - Public Key
  Specifies the new public key. You must enclose the new public key in double quotation marks.
- **-comment** `<text>` - Comment
  Specifies the new comment text for the public key.

**Examples**
The following command modifies the public key at index number 10 for the user named tsmith of Vserver vs1.

```
cluster1::> security login publickey modify -vserver vs1 -username tsmith -index 10 -publickey "ssh-rsa AAAAB3NzaC1yc2EAAAADAQABAAABAQDDD+pFzFgV/2dlowKRFgym9K910H/u+BTG8ctHteHy08thmaXT1GLCzaOC/12+XX1YKMRhJ00S9vo4QQKUXHaCPXFSgR5PnAs39set39ECCCLzmdupl1JnkWtX96pQH/bg2g3upFcFcC6z9c37uqFtNVPv8Asi1I/9WDQmEZJzmRt.JudJeU5GzwZw5ybgTaN1jxDWus9SS02C43F/vmoCKVT529UHt4/ePcaaHOGT1Q08+Qmm59uTgcfnpq53zYkepNQV8RdYtMdW1Rr44neh1W2rmW7xN4nxNvtEz99cb9s3yT8X1CKQfD0db+?T7y3X7Mif/gKQY6fosvjvZD"
```

security login publickey prepare-to-downgrade

Restore publickey features compatible with releases earlier than ONTAP 9.0.

**Availability:** This command is available to **cluster** administrators at the **advanced** privilege level.
Description
The security login publickey prepare-to-downgrade command disables the support for new publickey formats ecdsa and ed25519 in releases earlier than ONTAP 9.0.

Examples
The following command restores publickey features compatible with releases earlier than ONTAP 9.0:

```
cluster1:*> security login publickey prepare-to-downgrade
```

security login publickey show

Display public keys

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The security login publickey show command displays information about public keys.

Parameters

```
[-fields <fieldname>, ...]
```
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use -fields ? to display the fields to specify.

```
[-instance]
```
If you specify the -instance parameter, the command displays detailed information about all fields.

```
[-vserver <Vserver Name>] - Vserver
```
Selects the public keys that match this parameter value.

```
[-username <text>] - Username
```
Selects the public keys that match this parameter value.

```
[-index <integer>] - Index
```
Selects the public keys that match this parameter value.

```
[-publickey <certificate>] - Public Key
```
Selects the public keys that match this parameter value.

```
[-fingerprint <text>] - Hex Fingerprint
```
Selects the public keys that match this parameter value.

```
[-bubblebabble <text>] - Bubblebabble Fingerprint
```
Selects the public keys that match this parameter value.

```
[-comment <text>] - Comment
```
Selects the public keys that match this parameter value.

Examples
The example below displays public key information for the user named tsmith.

```
cluster1::> security login publickey show -username tsmith
UserName: tsmith Index: 5
Public Key: ssh-rsa AAAAB3NzaC1yc2EAAAABBlwAAAIAEAspH64CybuUsOQc6W22JnK6J

Fingerprint:
```

security login commands
security login role commands

Manage access control roles

security login role create

Add an access control role

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The security login role create command creates an access-control role. An access-control role consists of a role name and a command or directory to which the role has access. It optionally includes an access level (none, readonly, or all) and a query that applies to the specified command or command directory. After you create an access-control role, you can apply it to a management-utility login account by using the security login modify or security login create commands.

Parameters

-vserver <Vserver Name> - Vserver

This optionally specifies the Vserver name associated with the role.

-role <text> - Role Name

This specifies the role that is to be created.

-cmddirname <text> - Command / Directory

This specifies the command or command directory to which the role has access. To specify the default setting, use the special value "DEFAULT".

[-access <Access>] - Access Level

This optionally specifies an access level for the role. Possible access level settings are none, readonly, and all. The default setting is all.

[-query <query>] - Query

This optionally specifies the object that the role is allowed to access. The query object must be applicable to the command or directory name specified by -cmddirname. The query object must be enclosed in double quotation marks (""), and it must be a valid field name.

Examples

The following command creates an access-control role named "admin" for the vs1.example.com Vserver. The role has all access to the "volume" command but only within the "aggr0" aggregate.

```
ccluster1::> security login role create -role admin -cmddirname volume -query "-aggr aggr0" -access all -vserver vs1.example.com
```

Related references

security login modify on page 423

security login role delete
Delete an access control role

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**
The `security login role delete` command deletes an access-control role.

**Parameters**
- `vserver <Vserver Name>` - *Vserver*
  This optionally specifies the Vserver name associated with the role.
- `role <text>` - *Role Name*
  This specifies the role that is to be deleted.
- `cmddirname <text>` - *Command / Directory*
  This specifies the command or command directory to which the role has access. To specify the default setting, use the special value "DEFAULT".

**Examples**
The following command deletes an access-control role with the role name readonly and the command access "volume" for Vserver vs.example.com.

```
class1::> security login role delete -role readonly -cmddirname volume -vserver vs.example.com
```

security login role modify
Modify an access control role

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**
The `security login role modify` command modifies an access-control role.

**Parameters**
- `vserver <Vserver Name>` - *Vserver*
  This optionally specifies the Vserver name associated with the role.
- `role <text>` - *Role Name*
  This specifies the role that is to be modified.
- `cmddirname <text>` - *Command / Directory*
  This specifies the command or command directory to which the role has access. To specify the default setting for a role, use the special value "DEFAULT". This value can be modified only for the roles created for the admin Vserver.
- `[--access <Access>]]` - *Access Level*
  This optionally specifies a new access level for the role. Possible access level settings are none, readonly, and all. The default setting is all.
- `[--query <query>]]` - *Query*
  This optionally specifies the object that the role is allowed to access. The query object must be applicable to the command or directory name specified by -cmddirname. The query object must be enclosed in double quotation marks (""), and it must be a valid field name.
Examples
The following command modifies an access-control role with the role name readonly and the command access "volume" to have the access level readonly for Vserver vs.example.com:

```
cluster1::> security login role modify -role readonly -cmddirname volume -access readonly -vserver vs.example.com
```

security login role prepare-to-downgrade
Update role configurations so that they are compatible with earlier releases of Data ONTAP

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
The `security login role prepare-to-downgrade` command restores predefined roles of all Vservers earlier than Data ONTAP 8.3.2. You must run this command in advanced privilege mode when prompted to do so during the release downgrade.

Examples
The following command restores predefined roles of all Vservers earlier than Data ONTAP 8.3.2.

```
cluster1::*> security login role prepare-to-downgrade
```

security login role show
Show access control roles

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The `security login role show` command displays the following information about access-control roles:

- Role name
- Command or command directory to which the role has access
- Access level (none, read-only, or all)
- Query (detailed view only)

Parameters

```
[-fields <fieldname>, ...]
```

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

```
[-instance ]
```

If you specify the `-instance` parameter, the command displays detailed information about all fields.

```
[-vserver <Vserver Name>] - Vserver
```

Selects the roles that match this parameter value.

```
[-role <text>] - Role Name
```

Selects the roles that match this parameter value. If this parameter and the `-cmddirname` parameter are both used, the command displays detailed information about the specified access-control role.
security login role show-ontapi

Display the mapping between Data ONTAP APIs and CLI commands

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The security login role show-ontapi command displays Data ONTAP APIs (ONTAPIs) and the CLI commands that they are mapped to.

Parameters
{ [--fields <fieldname>, ...]  
If you specify the --fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use `--fields ?` to display the fields to specify.

[ [--instance]  
If you specify the --instance parameter, the command displays detailed information about all fields.

[ --ontapi <text> ] - ONTAPI Name
Use this parameter to view the corresponding CLI command for the specified API.

[ --command <text> ] - CLI Command
Use this parameter to view the corresponding API or APIs for the specified CLI command.

Examples
The following command displays all Data ONTAP APIs and their mapped CLI commands:

```bash
cluster1::> security login role show-ontapi
ONTAPI                      Command
--------------------------- ---------------------------------------------------
aggr-add                    storage aggregate add-disks
aggr-check-spare-low        storage aggregate check_spare_low
```

security login commands

443
security login role config commands

Manage the configuration of login roles

security login role config modify

Modify local user account restrictions

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The security login role config modify command modifies user account and password restrictions.

For the password character restrictions documented below (uppercase, lowercase, digits, etc.), the term "characters" refers to ASCII-range characters only - not extended characters.

Parameters

-vserver <vserver name> - Vserver

This specifies the Vserver name associated with the profile configuration.

-role <text> - Role Name

This specifies the role whose account restrictions are to be modified.
[-username-minlength <integer>] - Minimum Username Length Required
This specifies the required minimum length of the user name. Supported values are 3 to 16 characters. The default setting is 3 characters.

[-username-alphanum {enabled|disabled}] - Username Alpha-Numeric
This specifies whether a mix of alphabetic and numeric characters are required in the user name. If this parameter is enabled, a user name must contain at least one letter and one number. The default setting is disabled.

[-passwd-minlength <integer>] - Minimum Password Length Required
This specifies the required minimum length of a password. Supported values are 3 to 64 characters. The default setting is 8 characters.

[-passwd-alphanum {enabled|disabled}] - Password Alpha-Numeric
This specifies whether a mix of alphabetic and numeric characters is required in the password. If this parameter is enabled, a password must contain at least one letter and one number. The default setting is enabled.

[-passwd-min-special-chars <integer>] - Minimum Number of Special Characters Required in the Password
This specifies the minimum number of special characters required in a password. Supported values are from 0 to 64 special characters. The default setting is 0, which requires no special characters.

[-passwd-expiry-time <unsigned32_or_unlimited>] - Password Expires In (Days)
This specifies password expiration in days. A value of 0 means all passwords associated with the accounts in the role expire now. The default setting is unlimited, which means the passwords never expire.

[-require-initial-passwd-update {enabled|disabled}] - Require Initial Password Update on First Login
This specifies whether users must change their passwords when logging in for the first time. Initial password changes can be done only through SSH or serial-console connections. The default setting is disabled.

[-max-failed-login-attempts <integer>] - Maximum Number of Failed Attempts
This specifies the allowed maximum number of consecutive invalid login attempts. When the failed login attempts reach the specified maximum, the account is automatically locked. The default is 0, which means failed login attempts do not cause an account to be locked.

[-lockout-duration <integer>] - Maximum Lockout Period (Days)
This specifies the number of days for which an account is locked if the failed login attempts reach the allowed maximum. The default is 0, which means the accounts will be locked for 1 day.

[-disallowed-reuse <integer>] - Disallow Last 'N' Passwords
This specifies the number of previous passwords that are disallowed for reuse. The default setting is six, meaning that the user cannot reuse any of their last six passwords. The minimum allowed value is 6.

[-change-delay <integer>] - Delay Between Password Changes (Days)
This specifies the number of days that must pass between password changes. The default setting is 0.

[-delay-after-failed-login <integer>] - Delay after Each Failed Login Attempt (Secs)
This specifies the amount of delay observed by the system in seconds upon invalid login attempts. The default setting is 4 seconds.

[-passwd-min-lowercase-chars <integer>] - Minimum Number of Lowercase Alphabetic Characters Required in the Password
This specifies the minimum number of lowercase characters required in a password. Supported values are from 0 to 64 lowercase characters. The default setting is 0, which requires no lowercase characters.

[-passwd-min-uppercase-chars <integer>] - Minimum Number of Uppercase Alphabetic Characters Required in the Password
This specifies the minimum number of uppercase characters required in a password. Supported values are from 0 to 64 uppercase characters. The default setting is 0, which requires no uppercase characters.
[-passwd-min-digits <integer>] - Minimum Number of Digits Required in the Password

This specifies the minimum number of digits required in a password. Supported values are from 0 to 64 digits characters. The default setting is 0, which requires no digits.

[-passwd-expiry-warn-time <unsigned32 or unlimited>] - Display Warning Message Days Prior to Password Expiry (Days)

This specifies the warning period for password expiry in days. A value of 0 means warn user about password expiry upon every successful login. The default setting is unlimited, which means never warn about password expiry.

[-account-expiry-time <unsigned32 or unlimited>] - Account Expires in (Days)

This specifies account expiration in days. The default setting is unlimited, which means the accounts never expire. The account expiry time must be greater than account inactive limit.

[-account-inactive-limit <unsigned32 or unlimited>] - Maximum Duration of Inactivity before Account Expiration (Days)

This specifies inactive account expiry limit in days. The default setting is unlimited, which means the inactive accounts never expire. The account inactive limit must be less than account expiry time.

Examples

The following command modifies the user-account restrictions for an account with the role name admin for a Vserver named vs. The minimum size of the password is set to 12 characters.

```
cluster1:/> security login role config modify -role admin -vserver vs -passwd-minlength 12
```

security login role config reset

Reset RBAC characteristics supported on releases later than Data ONTAP 8.1.2

Availability: This command is available to cluster administrators at the advanced privilege level.

Description

The security login role config reset command resets the following role based access control (RBAC) characteristics to their default values. The system prompts you to run this command if you revert to Data ONTAP 8.1.2 or earlier. If you do not reset these characteristics, the revert process will fail.

- Minimum number of special characters required in password ("0")
- Password-expiration time, in days ("unlimited")
- Whether the password must be changed at the initial login ("disabled")
- Maximum number of failed login attempts permitted before the account is locked out ("0")
- Number of days that the user account is locked out after the maximum number of failed login attempts is reached ("0")

Examples

The following command resets the above mentioned RBAC characteristics of all cluster and Vserver roles to their default values.

```
cluster1:/> security login role config reset
```
security login role config show

Show local user account restrictions

Availability: This command is available to *cluster* administrators at the *admin* privilege level.

Description

The `security login role config show` command displays the following information about account restrictions for management-utility user accounts:

- Role name `-role`
- Minimum size of the password, in characters `-passwd-minlength`
- Whether the password requires alphanumeric characters `-passwd-alphanum`
- Number of previous passwords that cannot be reused `-disallowed-reuse`
- Minimum number of days that must elapse before users can change their passwords `-change-delay`

You can display detailed information about the restrictions on a specific account by specifying the `-role` parameter. This adds the following information:

- Minimum length of the user name, in characters `-username-minlength`
- Whether the user name requires alphanumeric characters `-username-alphanum`
- Minimum length of the password, in characters `-passwd-minlength`
- Whether the password requires alphanumeric characters `-passwd-alphanum`
- Minimum number of special characters required in password `-passwd-min-special-chars`
- Minimum number of lowercase characters required in password `-passwd-min-lowercase-chars`
- Minimum number of uppercase characters required in password `-passwd-min-uppercase-chars`
- Minimum number of digits required in password `-passwd-min-digits`
- Minimum number of days that must elapse before users can change their passwords `-change-delay`
- Whether the password must be changed at the initial login `-require-initial-passwd-update`
- Password-expiration time, in days `-passwd-expiry-time`
- Display warning message days prior to password expiry `-passwd-expiry-warn-time`
- Number of previous passwords that cannot be reused `-disallowed-reuse`
- Maximum number of failed login attempts permitted before the account is locked out `-max-failed-login-attempts`
- Number of days for which the user account is locked after the maximum number of failed login attempts is reached `-lockout-duration`
- Account-expiration time, in days `-account-expiry-time`
- Maximum duration of inactivity before account expiration, in days `-account-inactive-limit`
- Delay after each failed login attempt, in secs `-delay-after-failed-login`
Parameters

{-fields <fieldname>, ...}

If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use `-fields ?' to display the fields to specify.

{-instance}

If you specify the -instance parameter, the command displays detailed information about all fields.

{-vserver <vserver name>]} - Vserver

Selects the profile configurations that match this parameter value

{-role <text>]} - Role Name

If this parameter is specified, the command displays detailed information about restrictions for the specified user account.

{-username-minlength <integer>]} - Minimum Username Length Required

Selects the profile configurations that match this parameter value.

{-username-alphanum {enabled|disabled}]} - Username Alpha-Numeric

Selects the profile configurations that match this parameter value. Enabled means a user name must contain both letters and numbers.

{-passwd-minlength <integer>]} - Minimum Password Length Required

Selects the profile configurations that match this parameter value.

{-passwd-alphanum {enabled|disabled}]} - Password Alpha-Numeric

Selects the profile configurations that match this parameter value. Enabled means a password must contain both letters and numbers.

{-passwd-min-special-chars <integer>]} - Minimum Number of Special Characters Required in the Password

Selects the profile configurations that match this parameter value.

{-passwd-expiry-time <unsigned32_or_unlimited>]} - Password Expires In (Days)

Selects the profile configurations that match this parameter value.

{-require-initial-passwd-update {enabled|disabled}]} - Require Initial Password Update on First Login

Selects the profile configurations that match this parameter value.

{-max-failed-login-attempts <integer>]} - Maximum Number of Failed Attempts

Selects the profile configurations that match this parameter value.

{-lockout-duration <integer>]} - Maximum Lockout Period (Days)

Selects the profile configurations that match this parameter value.

{-disallowed-reuse <integer>]} - Disallow Last 'N' Passwords

Selects the profile configurations that match this parameter value.

{-change-delay <integer>]} - Delay Between Password Changes (Days)

Selects the profile configurations that match this parameter value.

{-delay-after-failed-login <integer>]} - Delay after Each Failed Login Attempt (Secs)

Selects the profile configurations that match this parameter value.

{-passwd-min-lowercase-chars <integer>]} - Minimum Number of Lowercase Alphabetic Characters Required in the Password

Selects the profile configurations that match this parameter value.

{-passwd-min-uppercase-chars <integer>]} - Minimum Number of Uppercase Alphabetic Characters Required in the Password

Selects the profile configurations that match this parameter value.
[-passwd-min-digits <integer>] - Minimum Number of Digits Required in the Password

Selects the profile configurations that match this parameter value.

[-passwd-expiry-warn-time <unsigned32_or_unlimited>] - Display Warning Message Days Prior to Password Expiry (Days)

Selects the profile configurations that match this parameter value.

[-account-expiry-time <unsigned32_or_unlimited>] - Account Expires in (Days)

Selects the profile configurations that match this parameter value.

[-account-inactive-limit <unsigned32_or_unlimited>] - Maximum Duration of Inactivity before Account Expiration (Days)

Selects the profile configurations that match this parameter value.

---

Examples

The example below displays restriction information about all user accounts:

```
cluster1::> security login role config show
----- Password Restrictions ----- 
Vserver    RoleName       Size AlphaNum NoReuse ChangeDelay 
----------- ------------- ---- -------- -------  -----------
vs         vsadmin         8  enabled       6      0 days  
vs         vsadmin-protocol 8 enabled       6     0 days  
vs         vsadmin-readonly 8 enabled       6      0 days 
vs         vsadmin-volume  8 enabled       6      0 days  
cluster1  admin            6  enabled       6      0 days  
cluster1  readonly         6  enabled       6      0 days  
```

---

security protocol commands

Manage application configuration

security protocol modify

Modify application configuration options

Availability: This command is available to cluster administrators at the advanced privilege level.

Description

The security protocol modify command modifies the existing cluster-wide configuration of RSH and Telnet. Enable RSH and Telnet in the cluster by setting the enabled field as true.

Parameters

- **-application <text>** - application

  Selects the application. Supported values are rsh and telnet.

- **[-enabled (true|false)]** - enabled

  Enables or disables the corresponding application. The default value is false.

Examples

The following command enables RSH in the cluster. The default setting for RSH is false:

```
cluster1::> security protocol modify -application rsh -enabled true
```

The following command enables Telnet in the cluster. The default setting for Telnet is false:
security protocol show

Show application configuration options

Availability: This command is available to cluster administrators at the advanced privilege level.

Description

The `security protocol show` command displays the cluster-wide configuration of RSH and Telnet in the cluster in advanced privilege mode. RSH and Telnet are disabled by default. Use the `security protocol modify` command to change the RSH and Telnet configuration that the cluster supports.

Parameters

`[-fields <fieldname>, ...]`

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

`[-instance]`

If you specify the `-instance` parameter, the command displays detailed information about all fields.

`[-application <text>] - application`

Displays the insecure applications in the cluster.

`[-enabled {true|false}] - enabled`

Displays whether the application is enabled or disabled in the cluster.

Examples

The following example shows the default security protocol configurations for a cluster:

```
cluster1::> security protocol show
Application      Enabled
-------------    -----------
    rsh          false
    telnet       false
```

The following example shows the security protocol configuration after RSH and Telnet have been enabled:

```
cluster1::> security protocol show
Application      Enabled
-------------    -----------
    rsh          true
    telnet       true
```

`security protocol modify` on page 449
Security Session Commands

Manage CLI and ONTAPI sessions and view request statistics

The security session commands provide statistics to monitor management session activity and limit configurations to control management session activity for specific categories.

security session kill-cli

Kill an active CLI session

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The security session kill-cli command is used to terminate active CLI sessions. If the session being killed is actively processing a non-read command, the kill will wait until the command is complete before terminating the session. If the session being killed is actively processing a read (show) command, the kill will wait until the current row is returned before terminating the session.

Parameters

- **node** \(<\text{nodename}>|\text{local}\) - Node
  
  Selects the sessions that match this parameter value. This identifies the node that is processing the session.

- **interface** \(\{\text{cli}|\text{ontapi}\}\) - Interface
  
  Selects the sessions that match this parameter value. This identifies the interface (CLI or ONTAPI) that is processing the session.

- **start-time** \(<\text{MM/DD HH:MM:SS}>\) - Start Time
  
  Selects the sessions that match this parameter value. This identifies the start time of the current active session.

- **session-id** \(<\text{integer}>\) - Session ID
  
  Selects the sessions that match this parameter value. This number uniquely identifies a management session within a given node.

- **vserver** \(<\text{vserver}>\) - Vserver
  
  Selects the sessions that match this parameter value. This identifies the Vserver associated with this management session.

- **username** \(<\text{text}>\) - Username
  
  Selects the sessions that match this parameter value. This identifies the authenticated user associated with this management session.

- **application** \(<\text{text}>\) - Client Application
  
  Selects the sessions that match this parameter value. This identifies the calling application by name.

- **location** \(<\text{text}>\) - Client Location
  
  Selects the sessions that match this parameter value. This identifies the location of the calling client application. This is typically the IP address of the calling client, or "console" or "localhost" for console or localhost connections.

- **idle-seconds** \(<\text{integer}>\) - Idle Seconds
  
  Selects the sessions that match this parameter value. When a session is not actively executing a command request (the session is idle), this indicates the time (in seconds) since the last request completed.

- **state** \(\{\text{pending}|\text{active}|\text{idle}\}\) - Session State
  
  Selects the sessions that match this parameter value. This identifies the state (pending, active, or idle) of the session. The state is "pending" if it hit a session limit and the session is waiting for another session to end. The
state is "idle" for CLI sessions that are waiting at the command prompt. The state is "active" if the session is actively working on a request.

[-request <text>] - Active Command

Selects the sessions that match this parameter value. This identifies the request (command) that is currently being handled by the session.

Examples

The following example illustrates killing a CLI session by specifying the node and the session id.

```
cluster1::> security session show -node node1
Node: node1               Interface: cli                                   Idle
Start Time     Sess ID Application Location           Vserver Username  Seconds
-------------- ------- ----------- ------------ ------------- -------- --------
03/27 16:58:13 1358    console     console           cluster1 admin           -
Active Seconds: 0 Request: security session show
03/27 16:58:17 1359    ssh         10.98.16.164      cluster1 admin         650
2 entries were displayed.
```

```
cluster1::> security session kill-cli -node node1 -session-id 1359
1 entry was acted on.
```

```
cluster1::> security session show -node node1
Node: node1               Interface: cli                                   Idle
Start Time     Sess ID Application Location           Vserver Username  Seconds
-------------- ------- ----------- ------------ ------------- -------- --------
03/27 16:58:13 1358    console     console           cluster1 admin           -
Active Seconds: 0 Request: security session show
```

The following example illustrates killing a CLI session by specifying the node and specifying a query on idle-seconds.

```
cluster1::> security session show -node node1
Node: node1               Interface: cli                                   Idle
Start Time     Sess ID Application Location           Vserver Username  Seconds
-------------- ------- ----------- ------------ ------------- -------- --------
03/27 16:58:13 1358    console     console           cluster1 admin           -
Active Seconds: 0 Request: security session show
03/27 17:13:36 1479    ssh         10.98.16.164      cluster1 admin          83
2 entries were displayed.
```

```
cluster1::> security session kill-cli -node node1 -session-id * -idle-seconds > 80
1 entry was acted on.
```

```
cluster1::> security session show
```

security session show

Show active CLI & ONTAPI sessions

Availability: This command is available to cluster administrators at the admin privilege level.
Description
The `security session show` command displays all active management sessions across the cluster.

Parameters

```
[-fields <fieldname>, ...]
    If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified
    field or fields. You can use `-fields ?` to display the fields to specify.

[-instance]
    If you specify the -instance parameter, the command displays detailed information about all fields.

[-node <nodename>|local] - Node
    Selects the sessions that match this parameter value. This identifies the node that is processing the session.

[-interface (cli|ontapi)] - Interface
    Selects the sessions that match this parameter value. This identifies the interface (CLI or ONTAPI) that is
    processing the session.

[-start-time <MM/DD HH:MM:SS>] - Start Time
    Selects the sessions that match this parameter value. This identifies the start time of the current active session.

[-session-id <integer>] - Session ID
    Selects the sessions that match this parameter value. This number uniquely identifies a management session
    within a given node.

[-vserver <vserver>] - Vserver
    Selects the sessions that match this parameter value. This identifies the Vserver associated with this
    management session.

[-username <text>] - Username
    Selects the sessions that match this parameter value. This identifies the authenticated user associated with this
    management session.

[-application <text>] - Client Application
    Selects the sessions that match this parameter value. This identifies the calling application by name.

[-location <text>] - Client Location
    Selects the sessions that match this parameter value. This identifies the location of the calling client
    application. This is typically the IP address of the calling client, or "console" or "localhost" for console or
    localhost connections.

[-ipspace <IPspace>] - IPspace of Location
    Selects the sessions that match this parameter value. This identifies the IPspace of the client location.

[-total <integer>] - Total Requests
    Selects the sessions that match this parameter value. This identifies the total number of requests that have been
    made thus far in the active session. The following commands are not counted: top, up, cd, rows, history, exit.

[-failed <integer>] - Failed Requests
    Selects the sessions that match this parameter value. This identifies the number of requests that have failed for
    any reason (including if they were blocked by configured limits).

[-max-time <integer>] - Maximum Time (ms)
    Selects the sessions that match this parameter value. This identifies the maximum amount of time (in
    milliseconds) that any request took for this session.

[-last-time <integer>] - Last Time (ms)
    Selects the sessions that match this parameter value. This identifies the amount of time (in milliseconds) that
    the last request took for this session.
```
[-total-seconds <integer>] - Total Seconds
Selects the sessions that match this parameter value. This identifies the total time (in seconds) that has been
taken by all completed requests for the current session; it does not include session idle time.

[-state {pending|active|idle}] - Session State
Selects the sessions that match this parameter value. This identifies the state (pending, active, or idle) of the
session. The state is "pending" if it hit a session limit and the session is waiting for another session to end. The
state is "idle" for CLI sessions that are waiting at the command prompt. The state is "active" if the session is
actively working on a request.

[-request <text>] - Request Input
Selects the sessions that match this parameter value. This identifies the request (command) that is currently
being handled by the session.

[-idle-seconds <integer>] - Idle Seconds
Selects the sessions that match this parameter value. When a session is not actively executing a command
request (the session is idle), this indicates the time (in seconds) since the last request completed.

[-active-seconds <integer>] - Active Seconds
Selects the sessions that match this parameter value. When a session is actively executing a command request,
this indicates the time (in seconds) since the current request started.

Examples
The following example illustrates displaying all active sessions across the cluster. In this example, we see one active
session on node node2 from the console application. We also see three active sessions on node node1. One is from the
console application and two are from the ssh application. Also one of the ssh sessions is from user diag and the other
ssh session is from user admin.

cluster1::> security session show
Node: node1               Interface: cli                                   Idle
Start Time     Sess ID Application Location           Vserver Username  Seconds
-------------- ------- ----------- ------------ ------------- -------- --------
03/27 16:58:13 1358    console     console           cluster1 admin           -
Active Seconds: 0  Request: security session show
03/27 17:17:04 1514    ssh         10.98.16.164      cluster1 admin         139
03/27 17:17:29 1515    ssh         10.98.16.164      cluster1 diag          115
Node: node2               Interface: cli                                   Idle
Start Time     Sess ID Application Location           Vserver Username  Seconds
-------------- ------- ----------- ------------ ------------- -------- --------
03/27 17:18:54 1509    console     console           cluster1 admin          23
4 entries were displayed.

The following example illustrates displaying all active sessions that have been idle for longer than 500 seconds.

cluster1::> security session show -idle-seconds > 500
Node: node1               Interface: cli                                   Idle
Start Time     Sess ID Application Location           Vserver Username  Seconds
-------------- ------- ----------- ------------ ------------- -------- --------
03/27 17:17:04 1514    ssh         10.98.16.164      cluster1 admin         607
03/27 17:17:29 1515    ssh         10.98.16.164      cluster1 diag          583
2 entries were displayed.

cluster1::>
Security Session Limit Commands

Manage management session limits

These commands allow management session limits to be configured for specific categories, including application, location, request, user, and Vserver. The default limits can be overridden for specific values within each category by using advanced privilege level commands.

security session limit create

Create default session limit

Availability: This command is available to cluster administrators at the admin privilege level.

Description
This command allows creation of a default management session limit that does not yet exist. The default limits can be overridden for specific values within each category by using advanced privilege level commands.

Parameters

- **interface {cli|ontapi} - Interface**
  The interface (CLI or ONTAPI) to which the limit applies.

- **category {application|location|request|user|vserver} - Category**
  The session type for this default limit. The following categories are supported: application, location, request, user, Vserver.

- **max-active-limit <integer> - Max-Active Limit**
  The maximum number of concurrent sessions allowed for this interface and category.

Examples

The following example illustrates creating a default limit for management sessions using the same application.

```
cluster1::> security session limit create -interface ontapi -category application -max-active-limit 8
```

security session limit delete

Delete default session limit

Availability: This command is available to cluster administrators at the admin privilege level.

Description
This command allows deletion of a default management session limit.

Parameters

- **interface {cli|ontapi} - Interface**
  The interface (CLI or ONTAPI) to which the limit applies.

- **category {application|location|request|user|vserver} - Category**
  The session type for this default limit. The following categories are supported: application, location, request, user, Vserver.
Examples
The following example illustrates deleting all default limits for CLI management sessions.

```
cluster1::> security session limit delete -interface cli -category *
3 entries were deleted.
```

security session limit modify

Modify default session limit

Availability: This command is available to cluster administrators at the admin privilege level.

Description
This command allows modification of a default management session limit.

Parameters
- `interface [cli|ontapi]` - Interface
  The interface (CLI or ONTAPI) to which the limit applies.
- `category [application|location|request|user|vserver]` - Category
  The session type for this default limit. The following categories are supported: application, location, request, user, Vserver.
- `[-max-active-limit <integer>]` - Max-Active Limit
  The maximum number of concurrent sessions allowed for this interface and category.

Examples
The following example illustrates modifying the default limit for CLI management sessions from the same location.

```
cluster1::> security session limit modify -interface cli -category location -max-active-limit 4
```

security session limit show

Show default session limits

Availability: This command is available to cluster administrators at the admin privilege level.

Description
This command shows the default management session limits that have been configured for each interface and category.

Parameters

```
[-fields <fieldname>, ...]
```
If you specify the `[-fields <fieldname>, ...]` parameter, the command output also includes the specified field or fields. You can use `'-fields ?' to display the fields to specify.

```
[-instance ]
```
If you specify the `[-instance ]` parameter, the command displays detailed information about all fields.
[-interface {cli|ontapi}] - Interface
Selects the sessions that match this parameter value. This identifies the interface (CLI or ONTAPI) to which the limit applies.

[-category {application|location|request|user|vserver}] - Category
Selects the sessions that match this parameter value. This identifies the category for the limit. The following categories are supported: application, location, request, user, and Vserver.

[-max-active-limit <integer>] - Max-Active Limit
Selects the sessions that match this parameter value. This identifies the configured limit that is used to throttle or reject requests.

Examples
The following example illustrates displaying the default limits for management sessions.

```
cluster1::> security session limit show
Interface Category  Max-Active
--------- ----------- ----------
cli  user         2
cli  vserver     4
ontapi vserver  2
3 entries were displayed.
```

Security Session Application Limit Commands
Manage per-application session limits
These commands allow management session limits to be configured for specific applications.

security session limit application create
Create per-application session limit

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
This command allows creation of a per-application management session limit that does not yet exist.

Parameters
- -interface {cli|ontapi} - Interface
   The interface (CLI or ONTAPI) to which the limit applies.
- -application <text> - Application
   The specified application to which this limit applies. The limit with the application name -default- is the limit used for any application without a specific configured limit.
- -max-active-limit <integer> - Max-Active Limit
   The maximum number of concurrent sessions allowed for this interface and application.

Examples
The following example illustrates creating a limit for management sessions from a custom application.
security session limit application delete

Delete per-application session limit

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
This command allows deletion of a per-application management session limit.

Parameters
- **interface** \{cli|ontapi\} - Interface
  The interface (CLI or ONTAPI) to which the limit applies.
- **application** <text> - Application
  The specified application to which this limit applies. The limit with the application name *default* is the limit used for any application without a specific configured limit.

Examples
The following example illustrates deleting a limit for management sessions from a custom application.

```
cluster1:*> security session limit application delete -interface ontapi -application "custom_app"
```

security session limit application modify

Modify per-application session limit

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
This command allows modification of a per-application management session limit.

Parameters
- **interface** \{cli|ontapi\} - Interface
  The interface (CLI or ONTAPI) to which the limit applies.
- **application** <text> - Application
  The specified application to which this limit applies. The limit with the application name *default* is the limit used for any application without a specific configured limit.
  
  **[-max-active-limit <integer>]** - Max-Active Limit
  The maximum number of concurrent sessions allowed for this interface and application.

Examples
The following example illustrates modifying management session limits for some custom applications.

```
cluster1:*> security session limit application modify -interface ontapi -application "custom_app" -max-active-limit 8
```
security session limit application show

Show per-application session limits

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
This command shows the per-application management session limits that have been configured for each interface and application.

Parameters
{-fields <fieldname>,...}
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

|-instance}
If you specify the -instance parameter, the command displays detailed information about all fields.

[-interface {cli|ontapi}] - Interface
Selects the sessions that match this parameter value. This identifies the interface (CLI or ONTAPI) to which the limit applies.

[-application <text>] - Application
Selects the sessions that match this parameter value. This identifies the application for the limit. The limit with the application name -default- is the limit used for any application without a specific configured limit.

[-max-active-limit <integer>] - Max-Active Limit
Selects the sessions that match this parameter value. This identifies the configured limit that is used to throttle or reject requests.

Examples
The following example illustrates displaying the per-application limits for ONTAPI management sessions.

```
cluster1::*> security session limit application show -interface ontapi
Interface Application          Max-Active
--------- -------------------- ----------
tonapi    -default-                     5
ntonapi    custom_app                   10
2 entries were displayed.
```

Security Session Location Limit Commands

Manage per-location session limits

These commands allow management session limits to be configured for specific locations.
**security session limit location create**

Create per-location session limit

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

**Description**
This command allows creation of a per-location management session limit that does not yet exist.

**Parameters**

- **-interface {cli|ontapi} - Interface**
  The interface (CLI or ONTAPI) to which the limit applies.

- **-location <text> - Location**
  The specified location to which this limit applies. The limit with the location name `-default-` (in the *Default* IPspace) is the limit used for any location (in any IPspace) without a specific configured limit.

- **[-ipspace <IPspace>] - IPspace of Location**
  This identifies the IPspace of the client location. If not specified, changes are made in the *Default* IPspace.

**max-active-limit <integer> - Max-Active Limit**
The maximum number of concurrent sessions allowed for this interface and location.

**Examples**
The following example illustrates creating a CLI limit for specific location.

```
cluster1:*> security session limit location create -interface cli -location 10.98.16.164 -max-active-limit 1
```

**security session limit location delete**

Delete per-location session limit

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

**Description**
This command allows deletion of a per-location management session limit.

**Parameters**

- **-interface {cli|ontapi} - Interface**
  The interface (CLI or ONTAPI) to which the limit applies.

- **-location <text> - Location**
  The specified location to which this limit applies. The limit with the location name `-default-` (in the *Default* IPspace) is the limit used for any location (in any IPspace) without a specific configured limit.

- **[-ipspace <IPspace>] - IPspace of Location**
  This identifies the IPspace of the client location. If not specified, changes are made in the *Default* IPspace.

**Examples**
The following example illustrates deleting limits for management sessions from a specific set of locations.
security session limit location modify

Modify per-location session limit

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
This command allows modification of a per-location management session limit.

Parameters
- -interface {cli|ontapi} - Interface
  The interface (CLI or ONTAPI) to which the limit applies.
- -location <text> - Location
  The specified location to which this limit applies. The limit with the location name -default- (in the Default IPspace) is the limit used for any location (in any IPspace) without a specific configured limit.
- [ -ipspace <IPspace> ] - IPspace of Location
  This identifies the IPspace of the client location. If not specified, changes are made in the Default IPspace.
- [ -max-active-limit <integer> ] - Max-Active Limit
  The maximum number of concurrent sessions allowed for this interface and location.

Examples
The following example illustrates modifying management sessions limits for specific locations.

cluster1::*> security session limit location modify -interface * -location 10.98.* -max-active-limit 2
3 entries were modified.

security session limit location show

Show per-location session limits

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
This command shows the per-location management session limits that have been configured for each interface and location.

Parameters
[-fields <fieldname>, ...]
  If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use -fields ? to display the fields to specify.
[-instance ]
  If you specify the -instance parameter, the command displays detailed information about all fields.
[-interface {cli|ontapi}] - Interface
   Selects the sessions that match this parameter value. This identifies the interface (CLI or ONTAPI) to which
   the limit applies.

[-location <text>] - Location
   Selects the sessions that match this parameter value. This identifies the location for the limit. The limit with
   the location name -default- (only in the Default IPspace) is the limit used for any location (in any
   IPspace) without a specific configured limit.

[-ipspace <IPspace>] - IPspace of Location
   Selects the sessions that match this parameter value. This identifies the IPspace of the client location. The
   default IPspace is Default.

[-max-active-limit <integer>] - Max-Active Limit
   Selects the sessions that match this parameter value. This identifies the configured limit that is used to throttle
   or reject requests.

Examples
   The following example illustrates displaying the per-location limits for management sessions.

   cluster1:.*> security session limit location show
   Interface Location     IPspace     Max-Active
   -------------------- ----------- ----------
   cli       -default-            Default             16
   cli       10.98.16.164         Default              0
   ontapi    -default-            Default              6
   ontapi    10.98.16.164         Default              0
   4 entries were displayed.

Security Session Request Limit Commands
   Manage per-request session limits
   These commands allow management session limits to be configured for specific requests.

security session limit request create
   Create per-request session limit

   Availability: This command is available to cluster administrators at the advanced privilege level.

   Description
   This command allows creation of a per-request management session limit that does not yet exist.

   Parameters
   -interface {cli|ontapi} - Interface
      The interface (CLI or ONTAPI) to which the limit applies.

   -request <text> - Request Name
      The specified request to which this limit applies. The limit with the request name -default- is the limit used
      for any request without a specific configured limit.

   -max-active-limit <integer> - Max-Active Limit
      The maximum number of concurrent sessions allowed for this interface and request.
Examples
The following example illustrates creating a limit for number of clients executing a specific API.

```
cluster1:*> security session limit request create -interface ontapi -request storage-disk-get-iter -max-active-limit 2
```

security session limit request delete
Delete per-request session limit

**Availability:** This command is available to cluster administrators at the *advanced* privilege level.

**Description**
This command allows deletion of a per-request management session limit.

**Parameters**
- `-interface {cli|ontapi}` - Interface
  The interface (CLI or ONTAPI) to which the limit applies.
- `-request <text>` - Request Name
  The specified request to which this limit applies. The limit with the request name `-default-` is the limit used for any request without a specific configured limit.

Examples
The following example illustrates deleting custom limits for that were configured for the volume commands and APIs.

```
cluster1:*> security session limit request delete -interface * -request volume*
4 entries were deleted.
```

security session limit request modify
Modify per-request session limit

**Availability:** This command is available to cluster administrators at the *advanced* privilege level.

**Description**
This command allows modification of a per-request management session limit.

**Parameters**
- `-interface {cli|ontapi}` - Interface
  The interface (CLI or ONTAPI) to which the limit applies.
- `-request <text>` - Request Name
  The specified request to which this limit applies. The limit with the request name `-default-` is the limit used for any request without a specific configured limit.
- `[-max-active-limit <integer>]` - Max-Active Limit
  The maximum number of concurrent sessions allowed for this interface and request.
Examples
The following example illustrates modifying the limit of the number of clients simultaneously executing a specific API.

```
cluster1::*> security session limit request modify -interface ontapi -request storage-disk-get-iter -max-active-limit 4
```

security session limit request show
Show per-request session limits

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
This command shows the per-request management session limits that have been configured for each interface and request.

Parameters

```
[-fields <fieldname>, ...]
```
If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

```
[-instance ]
```
If you specify the `-instance` parameter, the command displays detailed information about all fields.

```
[-interface {cli|ontapi}] - Interface
```
Selects the sessions that match this parameter value. This identifies the interface (CLI or ONTAPI) to which the limit applies.

```
[-request <text>] - Request Name
```
Selects the sessions that match this parameter value. This identifies the request (command or API) for the limit. The limit with the request name `-default-` is the limit used for any request without a specific configured limit.

```
[-max-active-limit <integer>] - Max-Active Limit
```
Selects the sessions that match this parameter value. This identifies the configured limit that is used to throttle or reject requests.

Examples
The following example illustrates displaying the per-request limits for management sessions.

```
cluster1::*> security session limit request show
<table>
<thead>
<tr>
<th>Interface Request</th>
<th>Max-Active</th>
</tr>
</thead>
<tbody>
<tr>
<td>cli</td>
<td>10</td>
</tr>
<tr>
<td>ontapi</td>
<td>5</td>
</tr>
<tr>
<td>ontapi</td>
<td>2</td>
</tr>
</tbody>
</table>
```

3 entries were displayed.

Security Session User Limit Commands
Manage per-user session limits

These commands allow management session limits to be configured for specific Vserver users.
security session limit user create

Create per-user session limit

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
This command allows creation of a per-user management session limit that does not yet exist.

Parameters
-\text{-interface (cli|ontapi)} - Interface
  The interface (CLI or ONTAPI) to which the limit applies.

-\text{-vserver <vserver>} - Vserver
  The specified Vserver to which this limit applies. The "Cluster" Vserver is used to limit Vservers that do not have a configured limit.

-\text{-user <text>} - User
  The specified user to which this limit applies. The limit with the user name \text{-default-} is the limit used for any user without a specific configured limit.

-\text{-max-active-limit <integer>} - Max-Active Limit
  The maximum number of concurrent sessions allowed for this interface, Vserver, and user.

Examples
The following example illustrates creating a per-user limit override for ONTAPI requests for the admin user in the admin Vserver.

\text{cluster1:*> security session limit user create -interface ontapi -vserver cluster1 -username admin -max-active-limit 16}

security session limit user delete

Delete per-user session limit

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
This command allows deletion of a per-user management session limit.

Parameters
-\text{-interface (cli|ontapi)} - Interface
  The interface (CLI or ONTAPI) to which the limit applies.

-\text{-vserver <vserver>} - Vserver
  The specified Vserver to which this limit applies. The "Cluster" Vserver is used to limit Vservers that do not have a configured limit.

-\text{-user <text>} - User
  The specified user to which this limit applies. The limit with the user name \text{-default-} is the limit used for any user without a specific configured limit.
Examples
The following example illustrates deleting all user-specific limits for CLI management sessions.

```
cluster1:*> security session limit user delete -interface cli -user !"-default-"
2 entries were deleted.
```

security session limit user modify

Modify per-user session limit

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

**Description**
This command allows modification of a per-user management session limit.

**Parameters**
- **-interface** *(cli|ontapi)* - Interface
  The interface (CLI or ONTAPI) to which the limit applies.
- **-vserver** `<vserver>` - Vserver
  The specified Vserver to which this limit applies. The "Cluster" Vserver is used to limit Vservers that do not have a configured limit.
- **-user** `<text>` - User
  The specified user to which this limit applies. The limit with the user name *-default-* is the limit used for any user without a specific configured limit.
- **[-max-active-limit <integer>]** - Max-Active Limit
  The maximum number of concurrent sessions allowed for this interface, Vserver, and user.

Examples
The following example illustrates modifying the admin user's limit for CLI management sessions.

```
cluster1:*> security session limit user modify -interface cli -vserver cluster1 -username admin -
max-active-limit 30
```

security session limit user show

Show per-user session limits

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

**Description**
This command shows the per-user management session limits that have been configured for each interface, Vserver, and user.

**Parameters**
```
[-fields <fieldname>, ...]
```
If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.
If you specify the `-instance` parameter, the command displays detailed information about all fields.

`[-interface {cli|ontapi}]` - Interface

Selects the sessions that match this parameter value. This identifies the interface (CLI or ONTAPI) to which the limit applies.

`[-vserver <vserver>]` - Vserver

Selects the sessions that match this parameter value. This identifies the Vserver for the limit. The "Cluster" Vserver is used to limit Vservers that do not have a configured limit.

`[-user <text>]` - User

Selects the sessions that match this parameter value. This identifies the user for the limit. The limit with the user name `-default-` is the limit used for any user without a specific configured limit.

`[-max-active-limit <integer>]` - Max-Active Limit

Selects the sessions that match this parameter value. This identifies the configured limit that is used to throttle or reject requests.

**Examples**

The following example illustrates displaying the per-user limits for CLI management sessions. In this example, there is a default limit of 4 sessions for each user. That limit is expanded to 8 for the admin Vserver. That limit is further expanded to 20 for the `admin` user in the admin Vserver.

```
cluster1::*> security session limit user show -interface cli
<table>
<thead>
<tr>
<th>Interface</th>
<th>Vserver</th>
<th>User</th>
<th>Max-Active</th>
</tr>
</thead>
<tbody>
<tr>
<td>cli</td>
<td>Cluster</td>
<td>-default-</td>
<td>4</td>
</tr>
<tr>
<td>cli</td>
<td>cluster1</td>
<td>-default-</td>
<td>8</td>
</tr>
<tr>
<td>cli</td>
<td>cluster1</td>
<td>admin</td>
<td>20</td>
</tr>
</tbody>
</table>
3 entries were displayed.
```

**Security Session Vserver Limit Commands**

Manage per-vserver session limits

These commands allow management session limits to be configured for specific Vservers.

`security session limit vserver create`

Create per-vserver session limit

*Availability:* This command is available to `cluster` administrators at the `advanced` privilege level.

**Description**

This command allows creation of a per-Vserver management session limit that does not yet exist.

**Parameters**

`[-interface {cli|ontapi}]` - Interface

The interface (CLI or ONTAPI) to which the limit applies.

`[-vserver <vserver>]` - Vserver

The specified Vserver to which this limit applies. The "Cluster" Vserver is used to limit Vservers that do not have a configured limit.

`[-max-active-limit <integer>]` - Max-Active Limit

The maximum number of concurrent sessions allowed for this interface and Vserver.
Examples
The following example illustrates creating a per-Vserver limit override for ONTAPI requests on the admin Vserver.

```
cluster1::*> security session limit vserver create -interface ontapi -vserver cluster1 -max-active-limit 4
```

security session limit vserver delete
Delete per-vserver session limit

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
This command allows deletion of a per-Vserver management session limit. The “Cluster” vserver is used when the specific Vserver doesn’t have a configured limit.

Parameters
- `interface {cli|ontapi}` - Interface
  The interface (CLI or ONTAPI) to which the limit applies.
- `vserver <vserver>` - Vserver
  The specified Vserver to which this limit applies. The “Cluster” Vserver is used to limit Vservers that do not have a configured limit.

Examples
The following example illustrates deleting all per-Vserver limits for management sessions except the default limit.

```
cluster1::*> security session limit vserver delete -interface * -vserver !Cluster
1 entries was deleted.
```

security session limit vserver modify
Modify per-vserver session limit

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
This command allows modification of a per-Vserver management session limit.

Parameters
- `interface {cli|ontapi}` - Interface
  The interface (CLI or ONTAPI) to which the limit applies.
- `vserver <vserver>` - Vserver
  The specified Vserver to which this limit applies. The “Cluster” Vserver is used to limit Vservers that do not have a configured limit.
- `[-max-active-limit <integer>]` - Max-Active Limit
  The maximum number of concurrent sessions allowed for this interface and Vserver.
Examples
The following example illustrates modifying the admin Vserver's limit for CLI management sessions.

cluster1:*> security session limit vserver modify -interface cli -vserver cluster1 -max-active-limit 40

security session limit vserver show
Show per-vserver session limits

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
This command shows the per-Vserver management session limits that have been configured for each interface and Vserver.

Parameters
{ [-fields <fieldname>,...]
  If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.
}

| [-instance ]
  If you specify the -instance parameter, the command displays detailed information about all fields.

[-interface {cli|ontapi}] - Interface
Selects the sessions that match this parameter value. This identifies the interface (CLI or ONTAPI) to which the limit applies.

[-vserver <vserver>] - Vserver
Selects the sessions that match this parameter value. This identifies the Vserver for the limit. The "Cluster" Vserver is used to limit Vservers that do not have a configured limit.

[-max-active-limit <integer>] - Max-Active Limit
Selects the sessions that match this parameter value. This identifies the configured limit that is used to throttle or reject requests.

Examples
The following example illustrates displaying the per-Vserver limits for management sessions.

cluster1:*> security session limit vserver show
Interface Vserver    Max-Active
--------------------- -------
c1i  Cluster  4
ontapi  Cluster  2
ontapi  cluster1  16
3 entries were displayed.

Security Session Request-Statistics Commands
View session request statistics
These commands provide historical statistics surrounding management session activity for specific categories, including application, location, request, user, and Vserver.
security session request-statistics show-by-application

Show session request statistics by application

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**
The `security session request-statistics show-by-application` command shows historical statistics for management session activity, categorized by application name. CLI sessions connections will have an application name based on the connection method, i.e.: `ssh`, `telnet`, `rsh`, `console`, or `ngsh`. ONTAPI sessions will extract the application name from the ZAPI request. ONTAP looks for the application name in the following three locations, in the following order of precedence:

1. The "X-Dot-Client-App" HTTP header;
2. The "app-name" attribute of the "netapp" element, within the ZAPI XML request;
3. The "User-Agent" HTTP header.

**Parameters**

`[-fields <fieldname>, ...]`
If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

`[-instance]`
If you specify the `-instance` parameter, the command displays detailed information about all fields.

`[-node {<nodename>|local}] - Node`
Selects the sessions that match this parameter value. This identifies the node that processed the session.

`[-interface {cli|ontapi}] - Interface`
Selects the sessions that match this parameter value. This identifies the interface (CLI or ONTAPI) that processed the session.

`[-application <text>] - Application`
Selects the sessions that match this parameter value. This identifies the calling application by name.

`[-total <integer>] - Total Requests`
Selects the sessions that match this parameter value. This identifies the total number of requests that have been made on a session. The following commands are not counted: top, up, cd, rows, history, exit.

`[-blocked <integer>] - Blocked Requests`
Selects the sessions that match this parameter value. This identifies the number of requests that were blocked due to configured limits.

`[-failed <integer>] - Failed Requests`
Selects the sessions that match this parameter value. This identifies the number of requests that failed for any reason (including if they were blocked by configured limits).

`[-max-time <integer>] - Maximum Time (ms)`
Selects the sessions that match this parameter value. This identifies the maximum amount of time (in milliseconds) that any request took.

`[-last-time <integer>] - Last Time (ms)`
Selects the sessions that match this parameter value. This identifies the amount of time (in milliseconds) that the last request took.

`[-active <integer>] - Number Active Now`
Selects the sessions that match this parameter value. This identifies the number of currently active sessions.
Selects the sessions that match this parameter value. This identifies the maximum number of concurrently active sessions.

- **last-active-seconds <integer>** - Seconds Since Last Session Start

Selects the sessions that match this parameter value. When a session is active, this indicates the time (in seconds) since the last session started.

- **idle-seconds <integer>** - Idle Seconds

Selects the sessions that match this parameter value. When no sessions are active, this indicates the time (in seconds) since the last session ended.

- **total-seconds <integer>** - Total Seconds

Selects the sessions that match this parameter value. This identifies the total time (in seconds) that have been taken by all completed requests; it does not include session idle time.

- **average-time <integer>** - Average Time (ms)

Selects the sessions that match this parameter value. This identifies the mean time spent processing requests.

- **success-percent <percent>** - Success Percent

Selects the sessions that match this parameter value. This identifies the percentage of successful requests.

- **blocked-percent <percent>** - Blocked Percent

Selects the sessions that match this parameter value. This identifies the percentage of requests that were blocked due to configured limits.

- **failed-percent <percent>** - Failed Percent

Selects the sessions that match this parameter value. This identifies the percentage of requests that failed for any reason (including if they were blocked by configured limits).

- **max-active-limit <integer>** - Max-Active Limit (privilege: advanced)

Selects the sessions that match this parameter value. This identifies the configured limit that is used to throttle or reject requests.

### Examples

The following example illustrates displaying historical statistics for all management session activity across the cluster, categorized by application name.

```plaintext
cluster1::> security session request-statistics show-by-application

Node: node1               Interface: cli                 Idle    Total
Application                  Total Now Max Pass Fail  Seconds  Seconds Avg (ms)
------------------------- -------- --- --- ---- ---- -------- -------- --------
console                       2126   0   6  95%   96       68      361      170
ssh                              6   2   3 100%    0        -      794   132444

Node: node2               Interface: cli                 Idle    Total
Application                  Total Now Max Pass Fail  Seconds  Seconds Avg (ms)
------------------------- -------- --- --- ---- ---- -------- -------- --------
console                       2090   0   6  95%   96      90      655      313
4 entries were displayed.

cluster1::>
```

The following example illustrates displaying historical statistics for management session activity on a specific node and for a specific application.
security session request-statistics show-by-application

Node: node1               Interface: ontapi              Idle    Total
Application                  Total Now Max Pass Fail  Seconds  Seconds Avg (ms)
------------------------- -------- --- --- ---- ---- -------- -------- --------
api_test                         2   0   1 100%    0      102        0       18

security session request-statistics show-by-location

Show session request statistics by location

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The security session request-statistics show-by-location command shows historical statistics for management session activity, categorized by client location.

Parameters

{ [-fields <fieldname>, ...]
  If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.
}

{ [-instance ]
  If you specify the -instance parameter, the command displays detailed information about all fields.
}

[-node {<nodename>|local}] - Node
  Selects the sessions that match this parameter value. This identifies the node that processed the session.

[-interface {cli|ontapi}] - Interface
  Selects the sessions that match this parameter value. This identifies the interface (CLI or ONTAPI) that processed the session.

[-location <text>] - Client Location
  Selects the sessions that match this parameter value. This identifies the location of the calling client application. This is typically the IP address of the calling client, or "console" or "localhost" for console or localhost connections.

[-ipspace <IPspace>] - IPspace of Location
  Selects the sessions that match this parameter value. This identifies the IPspace of the client location.

[-total <integer>] - Total Requests
  Selects the sessions that match this parameter value. This identifies the total number of requests that have been made on a session. The following commands are not counted: top, up, cd, rows, history, exit.

[-blocked <integer>] - Blocked Requests
  Selects the sessions that match this parameter value. This identifies the number of requests that were blocked due to configured limits.

[-failed <integer>] - Failed Requests
  Selects the sessions that match this parameter value. This identifies the number of requests that failed for any reason (including if they were blocked by configured limits).
[-max-time <integer>] - Maximum Time (ms)
Selects the sessions that match this parameter value. This identifies the maximum amount of time (in milliseconds) that any request took.

[-last-time <integer>] - Last Time (ms)
Selects the sessions that match this parameter value. This identifies the amount of time (in milliseconds) that the last request took.

[-active <integer>] - Number Active Now
Selects the sessions that match this parameter value. This identifies the number of currently active sessions.

[-max-active <integer>] - Max Number Active
Selects the sessions that match this parameter value. This identifies the maximum number of concurrently active sessions.

[-last-active-seconds <integer>] - Seconds Since Last Session Start
Selects the sessions that match this parameter value. When a session is active, this indicates the time (in seconds) since the last session started.

[-idle-seconds <integer>] - Idle Seconds
Selects the sessions that match this parameter value. When no sessions are active, this indicates the time (in seconds) since the last session ended.

[-total-seconds <integer>] - Total Seconds
Selects the sessions that match this parameter value. This identifies the total time (in seconds) that have been taken by all completed requests; it does not include session idle time.

[-average-time <integer>] - Average Time (ms)
Selects the sessions that match this parameter value. This identifies the mean time spent processing requests.

[-success-percent <percent>] - Success Percent
Selects the sessions that match this parameter value. This identifies the percentage of successful requests.

[-blocked-percent <percent>] - Blocked Percent
Selects the sessions that match this parameter value. This identifies the percentage of requests that were blocked due to configured limits.

[-failed-percent <percent>] - Failed Percent
Selects the sessions that match this parameter value. This identifies the percentage of requests that failed for any reason (including if they were blocked by configured limits).

[-max-active-limit <integer>] - Max-Active Limit (privilege: advanced)
Selects the sessions that match this parameter value. This identifies the configured limit that is used to throttle or reject requests.

---

**Examples**

### security session request-statistics show-by-request

Show session request statistics by request name

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**

The `security session request-statistics show-by-request` command shows historical statistics for management session activity, categorized by request (command or API name).

**Parameters**

- `[-fields <fieldname>, ...]`
  
  If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

- `[-instance ]`

  If you specify the `-instance` parameter, the command displays detailed information about all fields.

- `[-node {<nodename>|local}] - Node`

  Selects the sessions that match this parameter value. This identifies the node that processed the session.

- `[-interface {cli|ontapi}] - Interface`

  Selects the sessions that match this parameter value. This identifies the interface (CLI or ONTAPI) that processed the session.

- `[-request <text>] - Request Name`

  Selects the sessions that match this parameter value. This identifies the command associated with these requests.

- `[-total <integer>] - Total Requests`

  Selects the sessions that match this parameter value. This identifies the total number of requests that have been made on a session. The following commands are not counted: top, up, cd, rows, history, exit.

- `[-blocked <integer>] - Blocked Requests`

  Selects the sessions that match this parameter value. This identifies the number of requests that were blocked due to configured limits.
[-failed <integer>] - Failed Requests  
Selects the sessions that match this parameter value. This identifies the number of requests that failed for any reason (including if they were blocked by configured limits).

[-max-time <integer>] - Maximum Time (ms)  
Selects the sessions that match this parameter value. This identifies the maximum amount of time (in milliseconds) that any request took.

[-last-time <integer>] - Last Time (ms)  
Selects the sessions that match this parameter value. This identifies the amount of time (in milliseconds) that the last request took.

[-active <integer>] - Number Active Now  
Selects the sessions that match this parameter value. This identifies the number of currently active requests.

[-max-active <integer>] - Max Number Active  
Selects the sessions that match this parameter value. This identifies the maximum number of concurrently active requests.

[-last-active-seconds <integer>] - Seconds Since Last Request Start  
Selects the sessions that match this parameter value. When requests are active, this indicates the time (in seconds) since the last request started.

[-idle-seconds <integer>] - Idle Seconds  
Selects the sessions that match this parameter value. When no requests are active, this indicates the time (in seconds) since the last request ended.

[-total-seconds <integer>] - Total Seconds  
Selects the sessions that match this parameter value. This identifies the total time (in seconds) that have been taken by all completed requests; it does not include session idle time.

[-average-time <integer>] - Average Time (ms)  
Selects the sessions that match this parameter value. This identifies the mean time spent processing requests.

[-success-percent <percent>] - Success Percent  
Selects the sessions that match this parameter value. This identifies the percentage of successful requests.

[-blocked-percent <percent>] - Blocked Percent  
Selects the sessions that match this parameter value. This identifies the percentage of requests that were blocked due to configured limits.

[-failed-percent <percent>] - Failed Percent  
Selects the sessions that match this parameter value. This identifies the percentage of requests that failed for any reason (including if they were blocked by configured limits).

[-max-active-limit <integer>] - Max-Active Limit (privilege: advanced)  
Selects the sessions that match this parameter value. This identifies the configured limit that is used to throttle or reject requests.

Examples

The following example illustrates displaying historical statistics for all management session activity on a specific node, with a specific request query.

```
cluster1::> security session request-statistics show-by-request -node node1 -request network*
```

<table>
<thead>
<tr>
<th>Request Name</th>

</tbody>
</table>
**security session request-statistics show-by-user**

Show session request statistics by username

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**
The `security session request-statistics show-by-user` command shows historical statistics for management session activity, categorized by username. Entries for username 'autosupport' reflect commands that are executed by the AutoSupport OnDemand feature.

**Parameters**

```
[-fields <fieldname>, ...]  
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

[-instance]  
If you specify the -instance parameter, the command displays detailed information about all fields.

[-node <nodename> [local]] - Node  
Selects the sessions that match this parameter value. This identifies the node that processed the session.

[-interface {cli|ontapi}] - Interface  
Selects the sessions that match this parameter value. This identifies the interface (CLI or ONTAPI) that processed the session.

[-vserver <vserver>] - Vserver  
Selects the sessions that match this parameter value. This identifies the Vserver associated with this management session.

[-username <text>] - Username  
Selects the sessions that match this parameter value. This identifies the authenticated user associated with this management session.

[-total <integer>] - Total Requests  
Selects the sessions that match this parameter value. This identifies the total number of requests that have been made on a session. The following commands are not counted: top, up, cd, rows, history, exit.

[-blocked <integer>] - Blocked Requests  
Selects the sessions that match this parameter value. This identifies the number of requests that were blocked due to configured limits.

[-failed <integer>] - Failed Requests  
Selects the sessions that match this parameter value. This identifies the number of requests that failed for any reason (including if they were blocked by configured limits).

[-max-time <integer>] - Maximum Time (ms)  
Selects the sessions that match this parameter value. This identifies the maximum amount of time (in milliseconds) that any request took.
```
[-last-time <integer>] - Last Time (ms)
Selects the sessions that match this parameter value. This identifies the amount of time (in milliseconds) that
the last request took.

[-active <integer>] - Number Active Now
Selects the sessions that match this parameter value. This identifies the number of currently active sessions.

[-max-active <integer>] - Max Number Active
Selects the sessions that match this parameter value. This identifies the maximum number of concurrently
active sessions.

[-last-active-seconds <integer>] - Seconds Since Last Session Start
Selects the sessions that match this parameter value. When a session is active, this indicates the time (in
seconds) since the last session started.

[-idle-seconds <integer>] - Idle Seconds
Selects the sessions that match this parameter value. When no sessions are active, this indicates the time (in
seconds) since the last session ended.

[-total-seconds <integer>] - Total Seconds
Selects the sessions that match this parameter value. This identifies the total time (in seconds) that have been
taken by all completed requests; it does not include session idle time.

[-average-time <integer>] - Average Time (ms)
Selects the sessions that match this parameter value. This identifies the mean time spent processing requests.

[-success-percent <percent>] - Success Percent
Selects the sessions that match this parameter value. This identifies the percentage of successful requests.

[-blocked-percent <percent>] - Blocked Percent
Selects the sessions that match this parameter value. This identifies the percentage of requests that were
blocked due to configured limits.

[-failed-percent <percent>] - Failed Percent
Selects the sessions that match this parameter value. This identifies the percentage of requests that failed for
any reason (including if they were blocked by configured limits).

[-max-active-limit <integer>] - Max-Active Limit (privilege: advanced)
Selects the sessions that match this parameter value. This identifies the configured limit that is used to throttle
or reject requests.

Examples
The following example illustrates displaying historical statistics for all management session activity across the cluster,
categorized by username.

```
cluster1::> security session request-statistics show-by-user

Node: node1  Interface: cli  Idle  Total
Vserver   Username    Total Now Max Pass Fail  Seconds  Seconds Avg (ms)
----------  ---------  -------- --- --- ---- ---- -------- -------- --------
cluster1    admin       81   1   3  80%   16        -     1228    15171

Security Session Commands
The following example illustrates displaying historical statistics for management session activity on a specific node and for a specific username.

```
cluster1::> security session request-statistics show-by-user -node node1 -username diag
Node: node1               Interface: cli                 Idle    Total
Vserver          Username    Total Now Max Pass Fail  Seconds  Seconds Avg (ms)
-------------- ---------- -------- --- --- ---- ---- -------- -------- --------
cluster1             diag        1   0   1 100%    0        -     1511  1511958
```

**security session request-statistics show-by-vserver**

Show session request statistics by Vserver

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**
The `security session request-statistics show-by-vserver` command shows historical statistics for management session activity, categorized by vserver.

**Parameters**

```
[] [-fields <fieldname>, ...]
      If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

[] [-instance]
      If you specify the `-instance` parameter, the command displays detailed information about all fields.

[-node <nodename> | local] - Node
      Selects the sessions that match this parameter value. This identifies the node that processed the session.

[-interface {cli|ontapi}] - Interface
      Selects the sessions that match this parameter value. This identifies the interface (CLI or ONTAPI) that processed the session.

[-vserver <vserver>] - Vserver
      Selects the sessions that match this parameter value. This identifies the Vserver associated with this management session.

[-total <integer>] - Total Requests
      Selects the sessions that match this parameter value. This identifies the total number of requests that have been made on a session. The following commands are not counted: top, up, cd, rows, history, exit.

[-blocked <integer>] - Blocked Requests
      Selects the sessions that match this parameter value. This identifies the number of requests that were blocked due to configured limits.

[-failed <integer>] - Failed Requests
      Selects the sessions that match this parameter value. This identifies the number of requests that failed for any reason (including if they were blocked by configured limits).
```
[-max-time <integer>] - Maximum Time (ms)
Selects the sessions that match this parameter value. This identifies the maximum amount of time (in milliseconds) that any request took.

[-last-time <integer>] - Last Time (ms)
Selects the sessions that match this parameter value. This identifies the amount of time (in milliseconds) that the last request took.

[-active <integer>] - Number Active Now
Selects the sessions that match this parameter value. This identifies the number of currently active sessions.

[-max-active <integer>] - Max Number Active
Selects the sessions that match this parameter value. This identifies the maximum number of concurrently active sessions.

[-last-active-seconds <integer>] - Seconds Since Last Session Start
Selects the sessions that match this parameter value. When a session is active, this indicates the time (in seconds) since the last session started.

[-idle-seconds <integer>] - Idle Seconds
Selects the sessions that match this parameter value. When no sessions are active, this indicates the time (in seconds) since the last session ended.

[-total-seconds <integer>] - Total Seconds
Selects the sessions that match this parameter value. This identifies the total time (in seconds) that have been taken by all completed requests; it does not include session idle time.

[-average-time <integer>] - Average Time (ms)
Selects the sessions that match this parameter value. This identifies the mean time spent processing requests.

[-success-percent <percent>] - Success Percent
Selects the sessions that match this parameter value. This identifies the percentage of successful requests.

[-blocked-percent <percent>] - Blocked Percent
Selects the sessions that match this parameter value. This identifies the percentage of requests that were blocked due to configured limits.

[-failed-percent <percent>] - Failed Percent
Selects the sessions that match this parameter value. This identifies the percentage of requests that failed for any reason (including if they were blocked by configured limits).

[-max-active-limit <integer>] - Max-Active Limit (privilege: advanced)
Selects the sessions that match this parameter value. This identifies the configured limit that is used to throttle or reject requests.

**Examples**

The following example illustrates displaying historical statistics for all management session activity across the cluster, categorized by Vserver.

```
cluster1::> security session request-statistics show-by-vserver

Node: node1               Interface: cli                 Idle    Total
Vserver                      Total Now Max Pass Fail  Seconds  Seconds Avg (ms)  
------------------------- -------- --- --- ---- ---- -------- -------- --------
cluster1                      2725   1   8  94%  146        -     3052     1120

Node: node1               Interface: ontapi              Idle    Total
Vserver                      Total Now Max Pass Fail  Seconds  Seconds Avg (ms)  
------------------------- -------- --- --- ---- ---- -------- -------- --------
cluster1                         2   0   1 100%    0     2742        0       18
```

Security Session Commands

### security ssh commands

#### Manage SSH Configuration

#### security ssh add

Add SSH configuration options

**Availability:** This command is available to cluster and Vserver administrators at the admin privilege level.

**Description**

The `security ssh add` command adds additional SSH key exchange algorithms or ciphers or MAC algorithms to the existing configurations of the cluster or a Vserver. The added algorithms or ciphers or MAC algorithms are enabled on the cluster or Vserver. If you change the cluster configuration settings, it is used as the default for all newly created Vservers. The existing SSH key exchange algorithms, ciphers, and MAC algorithms remain unchanged in the configuration. If the SSH key exchange algorithms or ciphers or MAC algorithms are already enabled in the current configuration, the command will not fail. Data ONTAP supports the `diffie-hellman-group-exchange-sha256` key exchange algorithm for SHA-2. Data ONTAP also supports the `diffie-hellman-group-exchange-shal`, `diffie-hellman-group14-shal`, and `diffie-hellman-group1-shal` SSH key exchange algorithms for SHA-1. The SHA-2 key exchange algorithm is more secure than the SHA-1 key exchange algorithms. Data ONTAP also supports the `ecdh-sha2-nistp256`, `ecdh-sha2-nistp384`, `ecdh-sha2-nistp521`, and `curve25519-sha256`. Data ONTAP also supports the AES and 3DES symmetric encryptions (also known as ciphers) of the following types: `aes256-ctr`, `aes192-ctr`, `aes128-ctr`, `aes256-cbc`, `aes192-cbc`, `aes128-cbc`, `aes128-gcm`, `aes256-gcm`, and `3des-cbc`. Data ONTAP supports MAC algorithms of the following types: `hmac-shal`, `hmac-shal-96`, `hmac-md5`, `hmac-md5-96`, `hmac-ripemd160`, `umac-64`, `umac-64`, `umac-128`, `hmac-sha2-256`, `hmac-sha2-512`, `hmac-sha1-xml`, `hmac-sha1-96`, `hmac-sha2-256`, `hmac-sha2-512`, `hmac-sha1-xml`, `hmac-sha2-256`, `hmac-sha2-512`, `hmac-md5-etm`, `hmac-md5-96-etm`, `hmac-ripemd160`, `umac-64`, `umac-128`, and `umac-128-xml`.

**Parameters**

```
-vserver <Vserver Name> - Vserver
```

Identifies the Vserver to which you want to add additional SSH key exchange algorithms or ciphers.
[-key-exchange-algorithms <algorithm name>, ...] - List of SSH Key Exchange Algorithms to Add

Adds the specified SSH key exchange algorithm or algorithms to the Vserver.

[-ciphers <cipher name>, ...] - List of SSH Ciphers to Add

Adds the specified cipher or ciphers to the Vserver.

[-mac-algorithms <MAC name>, ...] - List of SSH MAC Algorithms to Add

Adds the specified MAC algorithm or algorithms to the Vserver.

Examples

The following command adds the diffie-hellman-group-exchange-sha256 and diffie-hellman-group-exchange-shal key exchange algorithms for the cluster1 Vserver. It also adds the aes256-cbc and aes192-cbc ciphers and the hmac-sha1 and hmac-sha2-256 MAC algorithms to the cluster1 Vserver.

cluster1::> security ssh add -vserver cluster1 -key-exchange-algorithms diffie-hellman-group-exchange-sha256,diffie-hellman-group-exchange-shal -ciphers aes256-cbc,aes192-cbc -mac-algorithms hmac-sha1,hmac-sha2-256

security ssh modify

Modify SSH configuration options

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description

The security ssh modify command replaces the existing configurations of the SSH key exchange algorithms or ciphers or MAC algorithms for the cluster or a Vserver with the configuration settings you specify. If you modify the cluster configuration settings, it will be used as the default for all newly created Vservers. Data ONTAP supports the diffie-hellman-group-exchange-sha256 key exchange algorithm for SHA-2. Data ONTAP also supports the diffie-hellman-group-exchange-shal, diffie-hellman-group14-shal, and diffie-hellman-group1-shal SSH key exchange algorithms for SHA-1. The SHA-2 key exchange algorithm is more secure than the SHA-1 key exchange algorithms. Data ONTAP also supports the AES and 3DES symmetric encryptions (also known as ciphers) of the following types: aes256-ctr, aes192-ctr, aes128-ctr, aes256-cbc, aes192-cbc, aes128-cbc, aes128-gcm, aes256-gcm, and 3des-cbc. Data ONTAP supports MAC algorithms of the following types: hmac-shal, hmac-shal-96, hmac-md5, hmac-md5-96, hmac-ripemd160, umac-64, umac-64, umac-128, hmac-shal2-256, hmac-shal2-512, hmac-shal-etal, hmac-shal-96-etal, hmac-shal2-256-etal, hmac-shal2-512-etal, hmac-md5-etal, hmac-md5-96-etal, hmac-ripemd160-etal, umac-64-etal, and umac-128-etal.

Parameters

-vserver <Vserver Name> - Vserver

Identifies the Vserver for which you want to replace the existing SSH key exchange algorithm and cipher configurations.

[-key-exchange-algorithms <algorithm name>, ...] - Key Exchange Algorithms

Enables the specified SSH key exchange algorithm or algorithms for the Vserver. This parameter also replaces all existing SSH key exchange algorithms with the specified settings.

[-ciphers <cipher name>, ...] - Ciphers

Enables the specified cipher or ciphers for the Vserver. This parameter also replaces all existing ciphers with the specified settings.

[-mac-algorithms <MAC name>, ...] - MAC Algorithms

Enables the specified MAC algorithm or algorithms for the Vserver. This parameter also replaces all existing MAC algorithms with the specified settings.
Examples

The following command enables the `diffie-hellman-group-exchange-sha256` and `diffie-hellman-group14-shal` key exchange algorithms for the cluster1 Vserver. It also enables the `aes256-ctr`, `aes192-ctr` and `aes128-ctr` ciphers, `hmac-shal` and `hmac-sha2-256` MAC algorithms for the cluster1 Vserver.

```
cluster1::> security ssh modify -vserver cluster1 -key-exchange-algorithms diffie-hellman-group-exchange-sha256,diffie-hellman-group14-shal -ciphers aes256-ctr,aes192-ctr,aes128-ctr -mac-algorithms hmac-shal,hmac-sha2-256
```

**security ssh prepare-to-downgrade**

Restore SSH configuration to releases earlier than Data ONTAP 9.0.0.

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

**Description**
The `security ssh prepare-to-downgrade` command restores the configurations of SSH key exchange algorithms and ciphers of all V servers and the cluster to their default settings prior to ONTAP 9.0. This command also disables the MAC configuration capability. You must run this command in advanced privilege mode when prompted to do so during the release downgrade. Otherwise, the release downgrade process will fail.

```
Examples

The following command restores the SSH security configurations of all Vservers and the cluster to the settings used before ONTAP 9.0.

```
```
cluster1::*> security ssh prepare-to-downgrade
```
```
security ssh remove

Remove SSH configuration options

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

**Description**
The `security ssh remove` command removes the specified SSH key exchange algorithms or ciphers from the existing configurations of the cluster or a Vserver. The removed algorithms or ciphers are disabled on the cluster or Vserver. If you changed the cluster configuration settings, it will be is used as the default for all newly created Vservers. If the SSH key exchange algorithms or ciphers that you specify with this command are not currently enabled, the command will not fail. Data ONTAP supports the `diffie-hellman-group-exchange-sha256` key exchange algorithm for SHA-2. Data ONTAP also supports the `diffie-hellman-group-exchange-shal`, `diffie-hellman-group14-shal`, and `diffie-hellman-group1-shal` key exchange algorithms for SHA-1. The SHA-2 key exchange algorithm is more secure than the SHA-1 key exchange algorithms. Data ONTAP also supports `ecdh-sha2-nistp256`, `ecdh-sha2-nistp384`, `ecdh-sha2-nistp521`, and `curve25519-sha256`. Data ONTAP also supports the AES and 3DES symmetric encryption (also known as ciphers) of the following types: `aes256-ctr`, `aes192-ctr`, `aes128-ctr`, `aes256-cbc`, `aes192-cbc`, `aes128-cbc`, `aes128-gcm`, `aes256-gcm` and `3des-cbc`. Data ONTAP also supports MAC algorithms of the following types: `hmac-shal`, `hmac-shal-96`, `hmac-md5`, `hmac-md5-96`, `hmac-ripemd160`, `umac-64`, `umac-64`, `umac-128`, `hmac-sha2-256`, `hmac-sha2-512`, `hmac-shal-16t`, `hmac-shal-96-etm`, `hmac-sha2-256-etm`, `hmac-sha2-512-etm`, `hmac-md5-etm`, `hmac-md5-96-etm`, `hmac-ripemd160-etm`, `umac-64-etm`, and `umac-128-etm`.

**Parameters**

- `vserver <Vserver Name>` - Vserver

  Identifies the Vserver from which you want to remove the SSH key exchange algorithms or ciphers.
[-key-exchange-algorithms <algorithm name>, ...] - List of SSH Key Exchange Algorithms to Remove
Removes the specified key exchange algorithm or algorithms from the Vserver.

[-ciphers <cipher name>, ...] - List of SSH Ciphers to Remove
Removes the specified cipher or ciphers from the Vserver.

[-mac-algorithms <MAC name>, ...] - List of SSH MAC algorithms to Remove
Removes the specified MAC algorithm or algorithms from the Vserver.

**Examples**
The following command removes the `diffie-hellman-group1-sha1` and `diffie-hellman-group-exchange-sha1` key exchange algorithms from the `cluster1` Vserver. It also removes the `aes128-cbc` and `3des-cbc` ciphers and the `hmac-sha1-96` and `hmac-sha2-256` MAC algorithms from the `cluster1` Vserver.

```bash
cluster1::> security ssh remove -vserver cluster1 -key-exchange-algorithms diffie-hellman-group1-sha1,diffie-hellman-group-exchange-sha1 -ciphers aes128-cbc,3des-cbc -mac-algorithms hmac-sha1-96,hmac-sha2-256
```

**security ssh show**
Display SSH configuration options

**Availability:** This command is available to `cluster` and `Vserver` administrators at the `admin` privilege level.

**Description**
The `security ssh show` command displays the configurations of the SSH key exchange algorithms, ciphers and MAC algorithms for the cluster and Vservers. The SSH protocol uses a Diffie-Hellman based key exchange method to establish a shared secret key during the SSH negotiation phrase. The key exchange method specifies how one-time session keys are generated for encryption and authentication and how the server authentication takes place. Data ONTAP supports the `diffie-hellman-group-exchange-sha256` key exchange algorithm for SHA-2. Data ONTAP also supports the `diffie-hellman-group-exchange-sha1`, `diffie-hellman-group14-sha1`, and `diffie-hellman-group1-sha1` key exchange algorithms for SHA-1. Data ONTAP also supports `ecdh-sha2-nistp256`, `ecdh-sha2-nistp384`, `ecdh-sha2-nistp521`, `curve25519-sha256`. Data ONTAP also supports the AES and 3DES symmetric encryptions (also known as ciphers) of the following types: `aes256-ctr`, `aes192-ctr`, `aes128-ctr`, `aes256-cbc`, `aes192-cbc`, `aes128-cbc`, `aes128-gcm`, `aes256-gcm` and `3des-cbc`. Data ONTAP supports MAC algorithms of the following types: `hmac-shal`, `hmac-shal-96`, `hmac-md5`, `hmac-md5-96`, `hmac-ripemd160`, `umac-64`, `umac-64`, `umac-128`, `hmac-sha2-256`, `hmac-sha2-512`, `hmac-sha-256`, `hmac-sha1-96`, `hmac-sha2-256-htm`, `hmac-sha2-256-htm`, `hmac-sha2-512-htm`, `hmac-md5-htm`, `hmac-md5-96-htm`, `hmac-ripemd160-htm`, `umac-64-htm`, `umac-128-htm`

**Parameters**

| [-fields <fieldname>, ...] |
| If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify. |

| [-instance ]] |
| If you specify the `-instance` parameter, the command displays detailed information about all fields. |

[-vserver <Vserver Name>] - Vserver
Identifies the Vserver for which you want to display the SSH key exchange algorithm, cipher, and MAC algorithm configurations.

[-key-exchange-algorithms <algorithm name>, ...] - Key Exchange Algorithms
Displays the Vserver or Vservers that have the specified key exchange algorithms enabled.
[-ciphers <cipher name>, ...] - Ciphers
 Displays the Vserver or Vservers that have the specified ciphers enabled.

[-mac-algorithms <MAC name>, ...] - MAC Algorithms
 Displays the Vserver or Vservers that have the specified MAC algorithm or algorithms.

Examples
The following command displays the enabled SSH key exchange algorithms, ciphers and MAC algorithms for the cluster and all Vservers. The cluster settings are used as the default for all newly created Vservers.

```
cluster1::> security ssh show
Vserver         Ciphers           Key Exchange Algorithms     MAC Algorithms

Virtual Server SSL Management

Manage the SSL configurations for a Vserver

These commands control the use of encrypted HTTP on Vservers, including whether SSL is available, which certificate is used for communication, and whether OCSP checks are enabled.

security ssl modify

Modify the SSL configuration for HTTP servers

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
This command modifies the configuration of encrypted HTTP (SSL) for Vservers in the cluster. Depending on the requirements of the individual node's or cluster's web services (displayed by the `vserver services web show` command), this encryption might or might not be used. If the Vserver does not have a certificate associated with it, SSL will not be available.

Parameters
-vserver <Vserver Name> - Vserver
 Identifies a Vserver for hosting SSL-encrypted web services.

[-ca <text>] - Server Certificate Issuing CA
 Identifies a Certificate Authority (CA) of a certificate to be associated with the instance of a given Vserver. If this parameter, along with serial, is omitted during modification, a self-signed SSL certificate can be optionally generated for that Vserver.

[-serial <text>] - Server Certificate Serial Number
 Identifies a serial number of a certificate to be associated with the instance of a given Vserver. If this parameter, along with ca, is omitted during modification, a self-signed SSL certificate can be optionally generated for that Vserver.
[-common-name <FQDN or Custom Common Name>] - Server Certificate Common Name

Identifies the common name (CN) of a certificate to be associated with the instance of a given Vserver. This parameter becomes optional if serial and ca are specified. You can use the `security certificate create` and `security certificate install` commands to add new certificates to Vservers.

**Note:** The use of self-signed SSL certificates exposes users to man-in-the-middle security attacks. Where possible, obtain a certificate that is signed by a reputable certificate authority (CA) and use the `security certificate install` command to configure it before enabling SSL on a Vserver.

[-server-enabled {true|false}] - SSL Server Authentication Enabled

Defines the working condition of SSL server authentication in an instance of the Vserver. Any Vserver with a valid certificate of type server is server-enabled.

[-client-enabled {true|false}] - SSL Client Authentication Enabled

Defines the working condition of SSL client authentication in an instance of the Vserver. Any Vserver with a valid certificate of type client-ca is client-enabled. It can only be enabled if server-enabled is true.

[-ocsp-enabled {true|false}] - Online Certificate Status Protocol Validation Enabled

This parameter enables OCSP validation of the client certificate chain. When this parameter is enabled, certificates in the certificate chain of the client will be validated against an OCSP responder after normal verification (including CRL checks) has occurred. The OCSP responder used for validation process is either extracted from the certificate itself, or it is derived by configuration.

[-ocsp-default-responder <text>] - URI of the Default Responder for OCSP Validation

This parameter sets the default OCSP responder to use. If this parameter is not enabled, the URI given will be used only if no responder URI is specified in the certificate that are being verified.

[-ocsp-force-responder {true|false}] - Force the Use of the Default Responder URI for OCSP Validation

This parameter forces the configured default OCSP responder to be used during OCSP certificate validation, even if the certificate that is being validated references an OCSP responder.

[-ocsp-timeout <[<integer>h][<integer>m][<integer>s]>]] - Timeout for OCSP Queries

Use this parameter to specify the timeout in seconds for OCSP responders. Specify zero for the minimum possible timeout. The default value is 10 seconds.

[-ocsp-max-response-age <unsigned32_or_unlimited>] - Maximum Allowable Age for OCSP Responses (secs)

This parameter sets the maximum allowable age (freshness) in seconds for the OCSP responses. The default value for this parameter is unlimited, which does not enforce a maximum age and the OCSP responses are considered valid as long as their expiration date field is in the future.

[-ocsp-max-response-time-skew <[<integer>h][<integer>m][<integer>s]>]] - Maximum Allowable Time Skew for OCSP Response Validation

This parameter sets the maximum allowable time difference for OCSP responses (when validating their ThisUpdate and NextUpdate fields).

[-ocsp-use-request-nonce {true|false}] - Use a NONCE within OCSP Queries

This parameter determines whether the queries to the OCSP responders should contain a NONCE or not. By default, a query NONCE is always used and checked against the OCSP response. When the responder does not use NONCEs, this parameter should be disabled.

**Note:** A NONCE is a unique identifier included in each OCSP request or OCSP response to prevent a replay attack.

### Examples

The following example enables SSL server authentication for a Vserver named vs0 with a certificate that has ca as www.example.com and serial as 4F4EB629.
The following example disables SSL server authentication for a Vserver name vs0.

```
cluster1::> security ssl modify -vserver vs0 -server-enabled false
```

The following example enables SSL client authentication for a Vserver named vs0.

```
cluster1::> security ssl modify -vserver vs0 -client-enabled true
```

The following example disables SSL client authentication for a Vserver named vs0.

```
cluster1::> security ssl modify -vserver vs0 -client-enabled false
```

- `vserver services web show` on page 1874

**security ssl show**

Display the SSL configuration for HTTP servers

**Availability:** This command is available to cluster and Vserver administrators at the admin privilege level.

**Description**

This command displays the configuration of encrypted HTTP (SSL) for Vservers in the cluster. Depending on the requirements of the individual node's or cluster's web services (displayed by the `vserver services web show` command), this encryption might or might not be used. If the Vserver does not have a certificate associated with it, SSL will not be available.

**Parameters**

```
[-fields <fieldname>, ...]
```

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

```
[-ocsp]
```

If you specify the `-ocsp` parameter, the command displays the Online Certificate Status Protocol configuration.

```
[-instance]
```

If you specify the `-instance` parameter, the command displays detailed information about all fields.

```
[-vserver <Vserver Name>] - Vserver
```

Identifies a Vserver for hosting SSL-encrypted web services.

```
[-ca <text>] - Server Certificate Issuing CA
```

Filters the display of SSL configuration by specifying the Certificate Authority (CA) that issued the server certificate.

```
[-serial <text>] - Server Certificate Serial Number
```

Filters the display of SSL configuration by specifying the serial number of a server certificate.

```
[-common-name <FQDN or Custom Common Name>] - Server Certificate Common Name
```

Filters the display of SSL configuration by specifying the common name for the server certificate.
[-server-enabled (true|false)] - SSL Server Authentication Enabled
Filters the display of SSL configuration according to whether the SSL server authentication is enabled or disabled. Vservers have self-signed certificates automatically generated during their creation. These Vserver self-signed certificates are server-enabled by default.

[-client-enabled (true|false)] - SSL Client Authentication Enabled
Filters the display of SSL configuration according to whether the SSL client authentication is enabled or disabled. You can enable client authentication only when server authentication is enabled.

[-ocsp-enabled (true|false)] - Online Certificate Status Protocol Validation Enabled
Filters the display of SSL configuration when the Online Certificate Status Protocol validation is enabled.

[-ocsp-default-responder <text>] - URI of the Default Responder for OCSP Validation
Filters the display of SSL configuration according to the URI of the default responder for OCSP validation.

[-ocsp-override-responder (true|false)] - Force the Use of the Default Responder URI for OCSP Validation
Filters the display of SSL configuration, which forces the use of the default responder URI for OCSP validation.

[-ocsp-responder-timeout <[<integer>h][<integer>m][<integer>s]>]- Timeout for OCSP Queries
Filters the display of SSL configuration according to the timeout for queries to OCSP responders.

[-ocsp-max-response-age <unsigned32_or_unlimited>] - Maximum Allowable Age for OCSP Responses (secs)
Filters the display of SSL configuration according to the maximum allowable age (freshness) in seconds for the OCSP responses.

[-ocsp-max-response-time-skew <[<integer>h][<integer>m][<integer>s]>]- Maximum Allowable Time Skew for OCSP Response Validation
Filters the display of SSL configuration according to the maximum allowable time difference for OCSP responses (when validating their ThisUpdate and NextUpdate fields).

[-ocsp-use-request-nonce (true|false)] - Use a NONCE within OCSP Queries
Filters the display of SSL configuration by specifying whether the queries to the OCSP responders should contain a NONCE or not.

Note: A NONCE is a unique identifier included in each OCSP request or OCSP response to prevent a replay attack.

Examples
The following example displays the configured certificates for Vservers.

```
cluster1::security ssl> show
Sensor          Server  Client
Vserver     Number  Common Name            Enabled    Enabled
----------  -------  ------------------------------- -------- --------
cluster1    516C3CB3 cluster1.company.com  true        true
vs0        516816D4 vs0.company.com         true        false
2 entries were displayed.
```

SnapLock Commands

Manages SnapLock attributes in the system.

The `snaplock` commands manage compliance-related functionality in the system. A volume created using the `volume create` command becomes a SnapLock volume when it is created on a SnapLock aggregate. A SnapLock aggregate is created using the `storage aggr create` command when the `snaplock-type` is specified as either `compliance` or `enterprise`.

The `snaplock compliance-clock` command can be used to manage the ComplianceClock in the system.

The `snaplock log` command can be used to manage SnapLock log infrastructure.

- `volume create` on page 1199
- `snaplock compliance-clock` on page 488
- `snaplock log` on page 490

SnapLock Clock commands

Manages ComplianceClock of nodes.

The `snaplock compliance-clock` manages the ComplianceClock of the system. ComplianceClock determines the expiry time of the SnapLock objects in the system. ComplianceClock can be initialized only once by the user and once it is set, it cannot be changed or altered by the user. There are two types of ComplianceClocks in the system:

- System ComplianceClock
- Volume ComplianceClock

System ComplianceClock (SCC) is maintained per node. SCC is used to update the Volume ComplianceClock and to provide a base value for Volume ComplianceClock for new SnapLock volumes. The SCC is initialized once by the user and takes the initial base value from the system clock. `snaplock compliance-clock show` can be used to check the value of the System ComplianceClock.

Volume ComplianceClock (VCC) is maintained per volume and is used as the time reference to calculate the expiry time of SnapLock objects in the SnapLock volume, such as files and the expiry date of the volume. `volume snaplock show` can be used to check the value of the Volume ComplianceClock.

**Related references**
- `snaplock compliance-clock show` on page 489
- `volume snaplock show` on page 1364

**snaplock compliance-clock initialize**

Initializes the node ComplianceClock

**Availability:** This command is available to `cluster` administrators at the `admin` privilege level.

**Description**

The `snaplock compliance-clock initialize` command is used to initialize System ComplianceClock from the system clock. System ComplianceClock can be initialized only once by the user. Once initialized, user cannot make any changes to the System ComplianceClock. Hence, user should ensure that system clock is correct before initializing the System ComplianceClock.
Parameters

- **node** *(<nodename>|local)* - Node
  Specifies the name of the node on which System ComplianceClock needs to be initialized.

- **[force true]** - Forces Initialization
  If you use this parameter, it will suppress the warning message during `snaplock compliance-clock initialize` operation.

Examples

```bash
cluster-1::> snaplock compliance-clock initialize -node node1
Warning: You are about to initialize the secure ComplianceClock of the node node1 to the current value of the node's system clock. This procedure can be performed only once on a given node, so you should ensure that the system time is set correctly before proceeding.
The current node's system clock is: Wed Nov 26 16:18:30 IST 2014
Do you want to continue? {y|n}: y
cluster-1::>
```

**snaplock compliance-clock show**

Displays the node ComplianceClock

**Availability:** This command is available to cluster administrators at the `admin` privilege level.

**Description**
The `snaplock compliance-clock show` command will display System ComplianceClock of the nodes in the cluster. It will display the following information:

- Node name
- ComplianceClock Time

**Parameters**

- **[fields <fieldname>, ...]**
  If you specify the `fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

- **[instance]**
  If you specify the `instance` parameter, the command displays detailed information about all fields.

- **[node (<nodename>|local)]** - Node
  If this parameter is specified, the command will display ComplianceClock for that particular node only.

- **[time <text>]** - ComplianceClock Time of the Node
  If this parameter is specified, the command will display nodes having the same `-time` value.
**Examples**

```
cluster1::> snaplock compliance-clock show
Node                  ComplianceClock Time
--------------------- -----------------------------
node1                 Mon Jan 12 11:34:15 IST 2015 +05:30
node2                 Mon Jan 12 11:34:10 IST 2015 +05:30
2 entries were displayed.
```

```
cluster1::> snaplock compliance-clock show -node node1
Node                  ComplianceClock Time
--------------------- -----------------------------
node1                 Mon Jan 12 11:34:45 IST 2015 +05:30
```

The following example shows the output when the session privilege level is "diagnostic".

```
cluster1::*> snaplock compliance-clock show
Node        ComplianceClock Time                Node ID    ID
----------- ----------------------------------- ---------- --------------
node1       Mon Jan 12 11:37:13 IST 2015 +05:30 4040216954 1418640203778
node2       ComplianceClock is not configured.
-          -
2 entries were displayed.
```

The following example shows the output when the session privilege level is "diagnostic".

```
cluster1::*> snaplock compliance-clock show -node node1
Node: node1
      ComplianceClock Time: Mon Jan 12 11:37:55 IST 2015 +05:30
      Node ID: 4040216954
      ID: 1418640203778
      ComplianceClock Time (secs): 1419002188
      ComplianceClock Skew (secs): 1014
```

**SnapLock Log commands**

Create and manage audit log configuration for a Vserver.

The `snaplock log` commands manage SnapLock log infrastructure for the SnapLock feature. This infrastructure provides the capability to record events that are required to provide an audit trail. These commands enable you to create and initialize the SnapLock log configuration for the Vserver, modify attributes associated with the SnapLock log configuration, and delete the auditlog configuration. Attributes of a SnapLock log configuration include the following:

- SnapLock log volume
- Maximum log size
- Default retention period

The SnapLock log volume is a SnapLock Compliance volume. The SnapLock log infrastructure creates directories and files in this volume to store the SnapLock log records.
The maximum log size specifies the maximum size of a log file that stores SnapLock log records. Once the file reaches this size, it is archived and a new log file is created.

The default retention period is the time period for which the log file is retained, if the SnapLock log records that are stored in the file do not carry any retention period.

**snaplock log create**

Create audit log configuration for a Vserver.

**Availability:** This command is available to cluster and Vserver administrators at the admin privilege level.

**Description**
The `snaplock log create` command is used to create a SnapLock log configuration for the Vserver. A SnapLock log configuration consists of volume to store the log, the maximum size of the log file, and the default period of time for which the log file should be retained.

**Parameters**

- `-vserver <vserver name>` - Vserver Name
  Specifies the name of the Vserver for which the configuration needs to be created.

- `-volume <volume name>` - Log Volume Name
  Specifies the name of the volume that is used for logging. This must be a SnapLock Compliance volume.

- `[-max-log-size {<integer>{KB|MB|GB|TB|PB}}]` - Maximum Size of Log File
  Specifies the maximum size of the log file. Once a log file reaches this limit, it is archived and a new log file is created. This parameter is optional. The default value is 10MB.

- `[-default-retention-period {{<integer> seconds|minutes|hours|days|months|years} | infinite}]` - Default Log Record Retention Period
  Specifies the default period of time a record (which is logged) is retained. This parameter is optional. The default value is "6 months".

**Examples**

```
class1::> snaplock log create -volume vol1 -max-log-size 50MB -default-retention-period "1 year" -vserver vsl
[Job 47] Job succeeded: SnapLock log created for Vserver "vsl".
```

**snaplock log delete**

Delete audit log configuration for a Vserver.

**Availability:** This command is available to cluster and Vserver administrators at the admin privilege level.

**Description**
The `snaplock log delete` command deletes the SnapLock log configuration associated with the Vserver. This command closes all the active log files in the log volume and mark the volume as disabled for SnapLock logging.

**Parameters**

- `-vserver <vserver name>` - Vserver Name
  Specifies the name of the Vserver whose SnapLock log configuration is deleted.
snaplock log modify

Modify audit log configuration for a Vserver.

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The snaplock log modify command modifies the SnapLock log configuration of the Vserver. Log volume, maximum size of log file, and default retention period can be modified. If the log volume is modified, then the active log files in the existing log volume is closed and the log volume is marked as disabled for logging. The new log volume is enabled for logging.

Parameters
- -vserver <vserver name> - Vserver Name
  Specifies the name of the Vserver for which the SnapLock log configuration needs to be modified.

- -volume <volume name> - Log Volume Name
  Specifies the new log volume that is configured for this Vserver for logging.

- -max-log-size {<integer> KB | MB | GB | TB | PB} - Maximum Size of Log File
  Specifies the new value for maximum log file size.

- -default-retention-period {<integer> seconds|minutes|hours|days|months|years | infinite}
  - Default Log Record Retention Period
  Specifies the new value for default retention period.

Examples

cluster1::> snaplock log delete -vserver vs1
[Job 47] Job succeeded: SnapLock log deleted for Vserver "vs1".

cluster1::> snaplock log modify -volume vol1 -vserver vs1 -max-log-size 15MB
[Job 48] Job succeeded: SnapLock log modified for Vserver "vs1".

snaplock log show

Display audit log configuration.

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The snaplock log show command displays the following information about the SnapLock log infrastructure:

- Vserver name
- Volume name
- Maximum log size
- Default retention period
Parameters
{[-fields <fieldname>, ...]
  If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

[-instance ]
  If you specify the -instance parameter, the command displays detailed information about all fields.

[-vserver <vserver name>] - Vserver Name
  If this parameter is specified, the command displays the log information for Vserveers that match the specified value.

[-volume <volume name>] - Log Volume Name
  If this parameter is specified, the command displays the log configuration for volumes that match the specified value.

[-max-log-size {<integer> [KB|MB|GB|TB|PB]}] - Maximum Size of Log File
  If this parameter is specified, the command displays the log configuration with a matching -max-log-size value.

[-default-retention-period {{<integer> seconds|minutes|hours|days|months|years} | infinite}] - Default Log Record Retention Period
  If this parameter is specified, the command displays the log configuration with a matching -default-retention-period value.

Examples

```
class1::> snaplock log show -vserver vs1
Vserver Name            : vs1
Log Volume Name         : 15MB
Maximum Size of Log File: 15MB
Default Log Record Retention Period : 6 months
```

```
class1::> snaplock log show
Vserver       Volume     Maximum Size  Retention Period
--------------- ------------- -----------------------------
vs1           voll        15MB                        6 months
```

SnapLock Log File commands
Manage Audit Log files of a Vserver.

The snaplock log file commands manage the log files used for recording events that need to be logged. Commands in this directory enable you to archive and close log files and display active log files.

snaplock log file archive
Archive Active Log Files in Log Volume

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.
Description
The snaplock log file archive command archives the currently active log file by closing it and creating a new active log file. If base-name is not provided, the command archives all active log files associated with the Vserver. Otherwise, the command archives the active log file associated with the base-name provided.

Parameters
-vserver <vserver name> - Vserver Name
   Specifies the name of the Vserver for which active log files need to be archived.

[base-name {privileged-delete | system}] - Base Name of Log File
   Specifies the log base-name, whose active log file needs to be archived. The base-name is the name of the source of log records. Valid base-names are system and privileged-delete. Each base-name has its own directory in which log files containing log records generated by base-name are stored.

Examples

    cluster1:/> snaplock log archive -vserver vs1
    [Job 48] Job succeeded: SnapLock log archived for Vserver "vs1".

snaplock log file show
Display audit log file information.

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The snaplock log file show command displays the following information about the log files:

- Vserver name
- Volume name
- File path
- Expiry time of the file
- File size

Parameters

- [fields <fieldname>, ...]
  If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

- [instance]
  If you specify the -instance parameter, the command displays detailed information about all fields.

-vserver <vserver name> - Vserver Name
   If this parameter is specified, then log files in the Vserver that match the specified value is displayed.

-base-name {privileged-delete | system} - Base Name of Log File
   If this parameter is specified, then the log files having a matching -base-name is displayed.

-volume <volume name> - Log Volume Name
   If this parameter is specified, then the log files in volumes that match the specified value are shown.
[-file-path <text>] - Log File Path
If this parameter is specified, then the log files that match the specified value are displayed.

[-expiry-time <text>] - Log File Expiry Time
If this parameter is specified, then the log files having a matching -expiry-time value are displayed.

[-file-size <integer> [KB|MB|GB|TB|PB]] - File Size
If this parameter is specified, then the log files having a matching -file-size value are displayed.

### Examples

```plaintext
cluster1::> snaplock log file show
Vserver       Volume              Base Name           File Path
----------------- ------------------- ------------------- ------------------------
vs1            vol1                system              /vol/vol1/snaplock_log/
                 system_logs/20160120_183756_GMT-present

cluster1::> snaplock log file show -vserver vs1 -base-name system
Vserver     : vs1
Volume      : vol1
Base Name   : system
File Path   : /vol/vol1/snaplock_log/system_logs/20160120_183756_GMT-present
File Size   : 560B
```

### SnapMirror Commands

#### Manage SnapMirror

The `snapmirror` commands enable you to create and manage data protection mirrors, extended data protection relationships, and load-sharing mirrors.

These commands are available to the cluster and Vserver administrators.

Note that there are "Pre 8.2" relationships: (1) load-sharing relationships; (2) data protection relationships with the source volume on a storage system running clustered Data ONTAP 8.1; (3) data protection relationships that existed before the source and destination storage systems were upgraded from clustered Data ONTAP 8.1 to clustered Data ONTAP 8.2 and later and have not yet been converted to ones with Data ONTAP 8.2 capabilities. These relationships have the same limitations as on Data ONTAP 8.1. In particular, only `snapmirror` commands present on Data ONTAP 8.1 can be used for these relationships. The "Relationship Capability" field, as shown in the output of the `snapmirror show` command, is set to "Pre 8.2" for these relationships. "Pre 8.2" data protection relationships can only be created and managed by the cluster administrator; load-sharing relationships which are all "Pre 8.2" can be created and managed by either a cluster or Vserver administrator.

Data protection relationships that existed before the source and destination storage systems were upgraded from Data ONTAP 8.1 will be auto-converted to "8.2 and above" with full capabilities when a Vserver peering relationship is set up between the source and destination Vservers. Relationships which have both the source and destination in the same Vserver and therefore require no Vserver peering relationship will be converted on the first boot when all nodes in the storage system are running Data ONTAP 8.2 or later. Note that since there is no "8.2 and above" implementation of load-sharing relationships, there is no conversion of load-sharing relationships to "8.2 and above".

snapmirror abort

Abort an active transfer

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description

The snapmirror abort command stops SnapMirror transfers that might have started and have not finished. A SnapMirror transfer is an operation on a given SnapMirror relationship, and the relationship is identified by its destination endpoint, which can be a volume or Vserver. You identify the SnapMirror relationship with this command and the command aborts the transfer for the relationship, and for load-sharing mirrors, transfers for associated relationships.

Load-sharing mirrors are either up to date and serving data to clients, or they are lagging and not serving data to clients. If the snapmirror abort command identifies an up-to-date load-sharing mirror, then SnapMirror transfers to the up-to-date load-sharing mirror and associated up-to-date load-sharing mirrors in the set of load-sharing mirrors are aborted. If the snapmirror abort command identifies a lagging load-sharing mirror, then only the SnapMirror transfer associated with the lagging load-sharing mirror is aborted.

After the snapmirror abort command successfully completes its operation, the volume on the receiving side of the transfer might contain a restart checkpoint. The restart checkpoint can be used by a subsequent transfer to restart and continue the aborted SnapMirror transfer.

This command is supported for SnapMirror relationships with the field "Relationship Capability" showing as either "8.2 and above" or "Pre 8.2" in the output of the snapmirror show command.

The use of wildcards in parameter values is not supported from the source Vserver or cluster for relationships with "Relationship Capability" of "8.2 and above".

You can use this command from the source or the destination Vserver or cluster for FlexVol volume relationships or Infinite Volume relationships.

For Vserver SnapMirror relationships, this command must be run only from the cluster containing the destination Vserver.

Parameters

\[-source-path | -S \{<vserver:>[volume]>|<[[cluster://]vserver//]volume>|<hostname:/lun/lun-name>\} - Source Path

Specifies the source endpoint of the SnapMirror relationship in one of two path formats. The normal format includes the names of the Vserver (vserver) and/or volume (volume). To support relationships with "Relationship Capability" of "Pre 8.2", a format which also includes the name of the cluster (cluster) is provided. The "Pre 8.2" format cannot be used when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above".

\[-source-cluster <Cluster name>\] - Source Cluster

Specifies the source cluster of the SnapMirror relationship. If this parameter is specified, the -source-vserver and -source-volume parameters must also be specified. This parameter is only applicable for relationships with "Relationship Capability" of "Pre 8.2". This parameter cannot be specified when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above".

\[-source-vserver <vserver name>\] - Source Vserver

Specifies the source Vserver of the SnapMirror relationship. For relationships with volumes as endpoints, if this parameter is specified, parameters -source-volume and for relationships with "Relationship Capability" of "Pre 8.2", -source-cluster must also be specified.
[-source-volume <volume name>] - Source Volume

Specifies the source volume of the SnapMirror relationship. If this parameter is specified, parameters -
source-vserver and for relationships with "Relationship Capability" of "Pre 8.2", -source-
cluster must also be specified.

[-destination-path {<vserver:<volume>|<cluster://vserver/volume>|<hostname:/lun/
lun-name>}] - Destination Path

Specifies the destination endpoint of the SnapMirror relationship in one of two path formats. The normal
format includes the names of the Vserver (vserver) and/or volume (volume). To support relationships with
"Relationship Capability" of "Pre 8.2", a format which also includes the name of the cluster
(cluster) is provided. The "Pre 8.2" format cannot be used when operating in a Vserver context on
relationships with "Relationship Capability" of "8.2 and above".

[-destination-cluster <Cluster name>] - Destination Cluster

Specifies the destination cluster of the SnapMirror relationship. If this parameter is specified, parameters
-destination-vserver and -destination-volume must also be specified. This parameter is only
applicable for relationships with "Relationship Capability" of "Pre 8.2". This parameter cannot be
specified when operating in a Vserver context on relationships with "Relationship Capability" of "8.2
and above".

-destination-vserver <vserver name> - Destination Vserver

Specifies the destination Vserver of the SnapMirror relationship. For relationships with volumes as endpoints,
if this parameter is specified, parameters -destination-volume and for relationships with
"Relationship Capability" of "Pre 8.2", -destination-cluster must also be specified.

-destination-volume <volume name> - Destination Volume

Specifies the destination volume of the SnapMirror relationship. If this parameter is specified, parameters
-destination-vserver and for relationships with "Relationship Capability" of "Pre 8.2", -
destination-cluster must also be specified.

[-hard | -h [true]] - Discard Restart Checkpoint

If this option is specified true, the restart checkpoint is discarded and the destination volume is restored to the
last Snapshot copy that was successfully transferred. You can use the -hard option to discard the restart
checkpoint of a previous transfer attempt which forces the subsequent transfer to start with a fresh Snapshot
copy on the destination volume. This option can only be used from the destination Vserver or cluster.

[-foreground | -w [true]] - Foreground Process

This specifies whether the operation runs as a foreground process. If this parameter is specified, the default
setting is true (the operation runs in the foreground). When set to true, the command will not return until
the process completes. This parameter is only applicable to relationships with "Relationship
Capability" of "Pre 8.2".

Examples

To stop the active SnapMirror replication to the destination volume vs2.example.com:dept_eng_dp_mirror1, type
the following command:

vs2.example.com::> snapmirror abort -destination-path
   vs2.example.com:dept_eng_dp_mirror1

For relationships with "Relationship Capability" of "Pre 8.2", to stop the active SnapMirror replication to the
destination volume cluster2://vs2.example.com/dept_eng_dp_mirror1, type the following command:

cluster2::> snapmirror abort -destination-path
   cluster2://vs2.example.com/dept_eng_dp_mirror1

To stop the active SnapMirror replication to the destination Vserver dvs1.example.com, type the following command:
cluster2::> snapmirror abort -destination-path
dvs1.example.com:

Under PVR control to stop user-initiated active SnapMirror replication to the destination Consistency Group cg_dst in Vserver vs2.example.com, type the following command:

vs2.example.com::> snapmirror abort -destination-path
   vs2.example.com:/cg/cg_dst

snapmirror break

Make SnapMirror destination writable

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description

The snapmirror break command breaks a SnapMirror relationship between a source and destination endpoint of a data protection mirror. The endpoint can be a Vserver or a volume. When Data ONTAP breaks the relationship, if the endpoint is a volume, the destination volume is made a read-write volume and can diverge from the source volume, client redirection is turned off on the destination volume, the restart checkpoint is cleared, and the clients can see the latest Snapshot copy. If the endpoint is a Vserver, the subtype of the destination Vserver is changed to default, volumes in the destination Vserver are made read-write and the clients can now access the Vserver namespace for modifications.

Subsequent manual or scheduled SnapMirror updates to the broken relationship will fail until the SnapMirror relationship is reestablished using the snapmirror resync command.

This command applies to data protection mirrors. For vault relationships, this command is only intended for use when preparing for a Data ONTAP revert operation (see the -delete-snapshots parameter in advanced privilege level). This command is not intended for use with load-sharing mirrors.

This command is supported for SnapMirror relationships with the field "Relationship Capability" showing as either "8.2 and above" or "Pre 8.2" in the output of the snapmirror show command.

The snapmirror break command must be used from the destination Vserver or cluster.

Parameters

{ [-source-path | -S {<vserver:[volume]> | <[cluster://vserver/]volume> | <[hostname://lun/lun-name]>}] - Source Path

  Specifies the source endpoint of the SnapMirror relationship in one of two path formats. The normal format includes the names of the Vserver (vserver) and/or volume (volume). To support relationships with "Relationship Capability" of "Pre 8.2", a format which also includes the name of the cluster (cluster) is provided. The "Pre 8.2" format cannot be used when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above".

  | [-source-cluster <Cluster name>] - Source Cluster

  Specifies the source cluster of the SnapMirror relationship. If this parameter is specified, the -source-vserver and -source-volume parameters must also be specified. This parameter is only applicable for
relationships with "Relationship Capability" of "Pre 8.2". This parameter cannot be specified when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above".

[-source-vserver <vserver name>] - Source Vserver

Specifies the source Vserver of the SnapMirror relationship. For relationships with volumes as endpoints, if this parameter is specified, parameters -source-volume and for relationships with "Relationship Capability" of "Pre 8.2", -source-cluster must also be specified.

[-source-volume <volume name>] - Source Volume

Specifies the source volume of the SnapMirror relationship. If this parameter is specified, parameters -source-vserver and for relationships with "Relationship Capability" of "Pre 8.2", -source-cluster must also be specified.

{ -destination-path {[vserver:]volume}> | {[cluster://vserver/]volume}|<[hostname:/]lun/ lun-name> } - Destination Path

Specifies the destination endpoint of the SnapMirror relationship in one of two path formats. The normal format includes the names of the Vserver (vserver) and/or volume (volume). To support relationships with "Relationship Capability" of "Pre 8.2", a format which also includes the name of the cluster (cluster) is provided. The "Pre 8.2" format cannot be used when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above".

[-destination-cluster <Cluster name>] - Destination Cluster

Specifies the destination cluster of the SnapMirror relationship. If this parameter is specified, parameters -destination-vserver and -destination-volume must also be specified. This parameter is only applicable for relationships with "Relationship Capability" of "Pre 8.2". This parameter cannot be specified when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above".

-destination-vserver <vserver name> - Destination Vserver

Specifies the destination Vserver of the SnapMirror relationship. For relationships with volumes as endpoints, if this parameter is specified, parameters -destination-volume and for relationships with "Relationship Capability" of "Pre 8.2", -destination-cluster must also be specified.

-destination-volume <volume name> - Destination Volume

Specifies the destination volume of the SnapMirror relationship. If this parameter is specified, parameters -destination-vserver and for relationships with "Relationship Capability" of "Pre 8.2", -destination-cluster must also be specified.

[-force | -f [true]] - Force

If this parameter is specified, the command proceeds without prompting for confirmation.

[-foreground | -w [true]] - Foreground Process

This specifies whether the operation runs as a foreground process. If this parameter is specified, the default setting is true (the operation runs in the foreground). When set to true, the command will not return until the process completes. This parameter is only applicable to relationships with "Relationship Capability" of "Pre 8.2".

[-delete-snapshots [true]] - Delete Snapshots for Revert (privilege: advanced)

Using this parameter causes break to delete Snapshot copies on a vault destination so that the system can be reverted. Note that the only Snapshot copies that will be deleted are those that were created with the current version of Data ONTAP. Any Snapshot copies that might be present created with a different version will not be deleted.

[-restore-destination-to-snapshot | -s <text>] - Restore Destination to Snapshot Copy

This optional parameter specifies the Snapshot copy to which the destination volume is restored after a successful break operation. If the parameter is not specified, the destination is restored to the latest Snapshot copy. This parameter is not supported for Vserver relationships.
Examples

To stop the SnapMirror replication to the destination volume vs2.example.com:dept_eng_dp_mirror1, type the following command:

```
vs2.example.com::> snapmirror break -destination-path vs2.example.com:dept_eng_dp_mirror1
```

For relationships with "Relationship Capability" of "Pre 8.2", to stop the SnapMirror replication to the destination volume cluster2://vs2.example.com/dept_eng_dp_mirror1, type the following command:

```
cluster2::> snapmirror break -destination-path cluster2://vs2.example.com/dept_eng_dp_mirror1
```

To stop replication to the destination Vserver dvs1.example.com of a Vserver SnapMirror relationship, type the following command:

```
cluster2::> snapmirror break -destination-path dvs1.example.com:
```

Under PVR control to stop synchronous SnapMirror replication to the destination Consistency Group cg_dst in Vserver vs2.example.com, type the following command:

```
vs2.example.com::> snapmirror break -destination-path vs2.example.com:/cg/cg_dst
```

snapmirror create

Create a new SnapMirror relationship

**Availability:** This command is available to cluster and Vserver administrators at the admin privilege level.

**Description**

The `snapmirror create` command creates a SnapMirror relationship between a source and destination endpoint. You can use this command to create a data protection relationship, a vault relationship, or a load-sharing relationship between FlexVol volumes. You can also use it to create a data protection relationship between Infinite Volumes and between Vservers. Infinite Volumes and Vservers support only data protection relationships. A SnapMirror relationship between Vservers can only be created if the system containing the source Vserver is also running Data ONTAP version 8.3 or later. Creating Vserver SnapMirror relationships is not supported for Vservers with Infinite Volumes.

Before using this command to create a SnapMirror relationship between Vservers, you typically create a source and destination Vserver using the `vserver create` command. The source Vserver should be of subtype default and the destination Vserver of subtype dp-destination. Also, before creating the relationship between Vservers, you must setup Vserver peer by using the `vserver peer create` command between the source and destination Vservers. A Vserver relationship cannot be created between two Vservers within the same cluster. The root volume of the destination Vserver will be read-write and data from the source Vserver's root volume will not be replicated. Hence there will be no volume level relationship created between the root volumes of the two Vservers.

After creating the relationship, the destination Vserver must be initialized by using the `snapmirror initialize` command.
Before using this command to create a volume SnapMirror relationship, you typically create a source and destination volume using the `volume create` command. The source volume should be in the online state and a read-write (RW) type. The destination volume should be in the online state and a data protection (DP) type.

You must also take the volume style into consideration when creating volume level SnapMirror relationships. Data ONTAP mirrors FlexVol volumes and Infinite Volumes.

For an Infinite Volume SnapMirror relationship, the destination Infinite Volume size must be greater than or equal to the source Infinite Volume size in bytes. You can verify the size in bytes by running set -units KB followed by volume show.

If all systems involved are running Data ONTAP version 8.2 and later, a Vserver peering relationship must be set up using the `vserver peer create` command between the source and the destination Vservers in order to create a relationship between the source and destination volumes. To enable interoperability with Data ONTAP version 8.1, if the source volume is on a storage system running clustered Data ONTAP version 8.1, the cluster administrator can create a data protection relationship between the source and destination volumes without a Vserver peering relationship between the source and destination Vservers. These relationships are managed the same way as on Data ONTAP 8.1 and the "Relationship Capability" field, as shown in the output of the `snapmirror show` command, is set to "Pre 8.2".

Note: SnapMirror relationships, except load-sharing relationships, which are created between two volumes which are both on a storage system running Data ONTAP version 8.2 and later have the "Relationship Capability" field set to "8.2 and above".

Load-sharing mirrors must be confined to a single Vserver; they are not allowed to span Vservers. Load-sharing relationships are created with the "Relationship Capability" field set to "Pre 8.2" even if both the source and destination volumes are on a storage system running Data ONTAP version 8.2 and later. There is no "8.2 and above" implementation for load-sharing relationships.

A set of load-sharing mirrors can have one or more destination volumes. You create separate SnapMirror relationships between the common source volume and each destination volume to create the set of load-sharing mirrors.

The source or destination of a load-sharing relationship cannot be the source or destination of any other SnapMirror relationship.

After creating the relationship, the destination volume can be initialized using the `snapmirror initialize` command. The destination volumes in a set of load-sharing mirrors are initialized using the `snapmirror initialize-ls-set` command. Load sharing mirrors are not supported for Infinite Volumes.

The `snapmirror create` command must be used from the destination Vserver or cluster.

**Parameters**

```
-s <[vserver:]volume> | <[cluster:]//vserver/volume> | [hostname:/lun/lun-name>]
```

- **Source Path**
  Specifies the source endpoint of the SnapMirror relationship in one of two path formats. The normal format includes the names of the Vserver (vserver) and/or volume (volume). To support relationships with "Relationship Capability" of "Pre 8.2", a format which also includes the name of the cluster (cluster) is provided. The "Pre 8.2" format cannot be used when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above".

```
-c Cluster name
```

- **Source Cluster**
  Specifies the source cluster of the SnapMirror relationship. If this parameter is specified, the `-source-vserver` and `-source-volume` parameters must also be specified. This parameter is only applicable for relationships with "Relationship Capability" of "Pre 8.2". This parameter cannot be specified when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above".

```
-s <vserver name>
```

- **Source Vserver**
  Specifies the source Vserver of the SnapMirror relationship. For relationships with volumes as endpoints, if this parameter is specified, parameters `-source-volume` and for relationships with "Relationship Capability" of "Pre 8.2", `-source-cluster` must also be specified.
[-source-volume <volume name>] - Source Volume

Specifies the source volume of the SnapMirror relationship. If this parameter is specified, parameters –
source-vserver and for relationships with "Relationship Capability" of "Pre 8.2", -source-
cluster must also be specified.

{ -destination-path {{<[vserver:]>[volume]>|<[[cluster:]/vserver/]volume>|<[hostname:]/lun/
lun-name>}} - Destination Path

Specifies the destination endpoint of the SnapMirror relationship in one of two path formats. The normal
format includes the names of the Vserver (vserver) and/or volume (volume). To support relationships with
"Relationship Capability" of "Pre 8.2", a format which also includes the name of the cluster
(cluster) is provided. The "Pre 8.2" format cannot be used when operating in a Vserver context on
relationships with "Relationship Capability" of "8.2 and above".

[-destination-cluster <Cluster name>] - Destination Cluster

Specifies the destination cluster of the SnapMirror relationship. If this parameter is specified, parameters –
destination-vserver and -destination-volume must also be specified. This parameter is only
applicable for relationships with "Relationship Capability" of "Pre 8.2". This parameter cannot be
specified when operating in a Vserver context on relationships with "Relationship Capability" of "8.2
and above".

-destination-vserver <vserver name> - Destination Vserver

Specifies the destination Vserver of the SnapMirror relationship. For relationships with volumes as endpoints,
if this parameter is specified, parameters -destination-volume and for relationships with
"Relationship Capability" of "Pre 8.2", -destination-cluster must also be specified.

-destination-volume <volume name> - Destination Volume

Specifies the destination volume of the SnapMirror relationship. If this parameter is specified, parameters –
destination-vserver and for relationships with "Relationship Capability" of "Pre 8.2", -
destination-cluster must also be specified.

[-type <snapmirrorType>] - Relationship Type

Specifies the type of SnapMirror relationship that will be created. You can create a data protection (DP)
relationship, an extended data protection (XDP) relationship, a transition data protection relationship between
a 7-Mode and a clustered Data ONTAP system (TDP), or a load-sharing (LS) relationship. The default value is
DP. Infinite Volumes support only data protection (DP) relationships.

-<vserver name> - Managing Vserver

If this optional parameter is specified, designates the managing Vserver. The managing Vserver is authorized
to use snapmirror commands to manage the SnapMirror relationship. The -vserver parameter is currently a
reserved parameter.

[-schedule <text>] - SnapMirror Schedule

This optional parameter designates the name of the schedule which is used to update the SnapMirror
relationship. If you do not designate a schedule, updates are not scheduled, so you must update the SnapMirror
relationship manually using the snapmirror update command or, in the case of a set of load-sharing
mirrors, using the snapmirror update-ls-set command.

**Note:** You define and name a schedule using the job schedule cron create command.

The schedules associated with an Infinite Volume SnapMirror relationship should not have an interval
shorter than hourly.

[-policy <sm_policy>] - SnapMirror Policy

This optional parameter designates the name of the SnapMirror policy which is associated with the
SnapMirror relationship. If you do not designate a policy, the DPDefault policy is applied to data protection
relationships and the XDPDefault policy is applied to extended data protection relationships. This parameter
is not applicable to relationships with "Relationship Capability" of "Pre 8.2".
In clustered Data ONTAP 8.2 data protection (DP) relationships were used for mirroring, while extended data protection (XDP) relationships were used for backup/vaulting. In clustered Data ONTAP 8.3 extended data protection (XDP) relationships support two more use cases, mirroring and unified mirror-vault. The exact behavior of an extended data protection (XDP) relationship is governed by the snapmirror policy associated with that relationship. In clustered ONTAP 8.3 the snapmirror policy has a new field type to indicate how the relationships with that policy will behave. The supported types are async-mirror (mirroring), vault (vaulting/backup) and mirror-vault (unified mirroring and vault). Refer to the man page for the snapmirror policy create command for more information.

Note: You define and name a policy using the snapmirror policy create command.

```
[-tries <unsigned32_or_unlimited>] - Tries Limit
```
This optional parameter specifies the maximum number of times to attempt each manual or scheduled transfer for a SnapMirror relationship. The default is eight times. The -tries parameter can be set to 0 to disable manual and scheduled updates for the SnapMirror relationship. This parameter is only applicable to relationships with "Relationship Capability" of "Pre 8.2". For relationships with "8.2 and above" capability, the tries limit is controlled by the value of tries in the SnapMirror policy which is associated with the relationship.

```
[-throttle | -k <throttleType>] - Throttle (KB/sec)
```
This optional parameter limits the network bandwidth used for transfers. It configures for the relationship the maximum rate (in Kbytes/sec) at which data can be transferred. If no throttle is configured, by default the SnapMirror relationship fully utilizes the network bandwidth available. You can also configure the relationship to fully use the network bandwidth available by explicitly setting the throttle to unlimited or 0. The minimum effective throttle value is four Kbytes/sec, so if you specify a throttle value between 1 and 4, it will be treated as 4. The -throttle parameter does not affect load-sharing mirrors and other SnapMirror relationships with "Relationship Capability" of "Pre 8.2" confined to a single cluster.

```
[-identity-preserve {true|false}] - Identity Preserve Vserver DR
```
Specifies whether or not the identity of the source Vserver is replicated to the destination Vserver of the Vserver SnapMirror relationship that will be created. If this parameter is set to true, the source Vserver's configuration will additionally be replicated to the destination. If the parameter is set to false, then only the source Vserver's volumes and RBAC configuration are replicated to the destination. This parameter is applicable only for SnapMirror relationships with Vserver endpoints. The default value is false.

### Examples
To create a data protection mirror between the source endpoint vs1.example.com:dept_eng, and the destination endpoint vs2.example.com:dept_eng_dp_mirror2, type the following command:

```
vs2.example.com::> snapmirror create -destination-path vs2.example.com:dept_eng_dp_mirror2 -source-path vs1.example.com:dept_eng -type DP
```

To create a data protection mirror between the source endpoint cluster1://vs1.example.com/dept_eng, and the destination endpoint cluster2://vs2.example.com/dept_eng_dp_mirror2 when the source cluster is running Data ONTAP 8.1 software, type the following command:

```
cluster2::> snapmirror create -destination-path cluster2://vs2.example.com/dept_eng_dp_mirror2 -source-path cluster1://vs1.example.com/dept_eng -type DP
```

To create a load-sharing mirror between the source endpoint cluster1://vs1.example.com/mkt1, and the destination endpoint cluster1://vs1.example.com/mkt1_ls1 with the schedule named 5min used to update the relationship, type the following command:

```
cluster1::> snapmirror create -source-path cluster1://vs1.example.com/mkt1 -destination-path cluster1://vs1.example.com/mkt1_ls1 -type LS -folder cluster1://vs1.example.com/mkt1 -schedule 5min
```
To create a SnapMirror relationship between the source Vserver `vsl.example.com`, and the destination Vserver `dvsl.example.com` with the schedule named `hourly` used to update the relationship, type the following command:

```
cluster2::> snapmirror create
    -destination-path dvsl.example.com:
    -source-path vsl.example.com:
    -schedule hourly
```

Under PVR control to create a SnapMirror synchronous Consistency Group relationship with the following attributes:

- It is between the source Consistency Group `cg_src` in Vserver `vsl.example.com`, and the destination Consistency Group `cg_dst` in Vserver `vs2.example.com`.
- It has item mappings between `lun1` and `lun2` on volume `srcvol` and `lun1` and `lun2` on volume `dstvol`.
- It uses a policy named `Sync` that has a policy type of `sync-mirror` that the user has previously created.

```
vs2.example.com::> snapmirror create
    -destination-path vs2.example.com:/cg/cg_dst
    -source-path vs1.example.com:/cg/cg_src
    -type XDP -policy Sync
    -cg-item-mappings /vol/srcvol/lun1:@/vol/dstvol/lun1,
    /vol/srcvol/lun2:@/vol/dstvol/lun2
```

Under PVR control to create a new item mapping between `lun3` on volume `srcvol` and `lun3` on volume `dstvol` in the existing SnapMirror synchronous Consistency Group relationship that was created above, type the following command:

```
vs2.example.com::> snapmirror create
    -destination-path vs2.example.com:/cg/cg_dst
    -source-path vs1.example.com:/cg/cg_src
    -type XDP -policy Sync
    -cg-item-mappings /vol/srcvol/lun3:@/vol/dstvol/lun3
```

snapmirror delete

Delete a SnapMirror relationship

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

**Description**

The `snapmirror delete` command removes the SnapMirror relationship between a source endpoint and a destination endpoint. The endpoint can be a Vserver or a volume. The Vservers and the volumes are not destroyed and Snapshot copies on the volumes are not removed.

The `snapmirror delete` command fails if a SnapMirror transfer for the SnapMirror relationship is in progress for relationships with "**Relationship Capability**" of "Pre 8.2". For relationships with "**8.2 and above**" capability the delete will succeed even if a transfer is in progress and the transfer will ultimately stop.

A set of load-sharing mirrors can contain multiple destination volumes, each destination volume having a separate SnapMirror relationship with the common source volume. When used on one of the SnapMirror relationships from the set of load-sharing mirrors, the `snapmirror delete` command deletes the specified SnapMirror relationship from the set of load-sharing mirrors.

The `snapmirror delete` command preserves the read-write or read-only attributes of the volumes of a SnapMirror relationship after the relationship is deleted. Therefore, a read-write volume that was the source of a SnapMirror relationship retains its read-write attributes, and a data protection volume or a load-sharing volume that was a destination of a SnapMirror relationship retains its read-only attributes. Similarly, the subtype attribute of source and destination Vservers is not modified when a Vserver SnapMirror relationship is deleted.

**Note:** When a SnapMirror relationship from a set of load-sharing mirrors is deleted, the destination volume becomes a data protection volume and retains the read-only attributes of a data protection volume.

This command is supported for SnapMirror relationships with the field "**Relationship Capability**" showing as either "**8.2 and above**" or "**Pre 8.2**" in the output of the `snapmirror show` command.

For relationships with "**Relationship Capability**" of "**8.2 and above**", the `snapmirror delete` command must be used from the destination Vserver or cluster. The SnapMirror relationship information is deleted from the destination Vserver, but no cleanup or deletion is performed on the source Vserver. The `snapmirror release` command must be issued on the source Vserver to delete the source relationship information.

For relationships with "**Relationship Capability**" of "**Pre 8.2**", you can use this command from the source or from the destination cluster. When used from the destination cluster, the SnapMirror relationship information on the source and destination clusters is deleted. When used from the source cluster, only the SnapMirror relationship information on the source cluster is deleted. The use of `snapmirror delete` on a source cluster is not supported for an Infinite Volume relationships in this release.

**Parameters**

```
[[-source-path | -S {<vserver:/volume>|<cluster://vserver/volume>|<hostname:/lun/lun-name>}] - Source Path

  Specifies the source endpoint of the SnapMirror relationship in one of two path formats. The normal format includes the names of the Vserver (vserver) and/or volume (volume). To support relationships with "**Relationship Capability**" of "**Pre 8.2**", a format which also includes the name of the cluster (cluster) is provided. The "**Pre 8.2**" format cannot be used when operating in a Vserver context on relationships with "**Relationship Capability**" of "**8.2 and above**".

  | [-source-cluster <Cluster name>] - Source Cluster

  Specifies the source cluster of the SnapMirror relationship. If this parameter is specified, the `-source-vserver` and `-source-volume` parameters must also be specified. This parameter is only applicable for relationships with "**Relationship Capability**" of "**Pre 8.2**". This parameter cannot be specified when operating in a Vserver context on relationships with "**Relationship Capability**" of "**8.2 and above**".
```
[-source-vserver <vserver name>] - Source Vserver

Specifies the source Vserver of the SnapMirror relationship. For relationships with volumes as endpoints, if this parameter is specified, parameters -source-volume and for relationships with "Relationship Capability" of "Pre 8.2", -source-cluster must also be specified.

[-source-volume <volume name>] - Source Volume

Specifies the source volume of the SnapMirror relationship. If this parameter is specified, parameters -source-vserver and for relationships with "Relationship Capability" of "Pre 8.2", -source-cluster must also be specified.

{-destination-path (<[vserver:]<volume>|<([cluster:]//vserver/)volume>|<[hostname:]|lun/lun-name>)} - Destination Path

Specifies the destination endpoint of the SnapMirror relationship in one of two path formats. The normal format includes the names of the Vserver (vserver) and/or volume (volume). To support relationships with "Relationship Capability" of "Pre 8.2", a format which also includes the name of the cluster (cluster) is provided. The "Pre 8.2" format cannot be used when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above".

[-destination-cluster <Cluster name>] - Destination Cluster

Specifies the destination cluster of the SnapMirror relationship. If this parameter is specified, parameters -destination-vserver and -destination-volume must also be specified. This parameter is only applicable for relationships with "Relationship Capability" of "Pre 8.2". This parameter cannot be specified when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above".

-destination-vserver <vserver name> - Destination Vserver

Specifies the destination Vserver of the SnapMirror relationship. For relationships with volumes as endpoints, if this parameter is specified, parameters -destination-volume and for relationships with "Relationship Capability" of "Pre 8.2", -destination-cluster must also be specified.

-destination-volume <volume name> - Destination Volume

Specifies the destination volume of the SnapMirror relationship. If this parameter is specified, parameters -destination-vserver and for relationships with "Relationship Capability" of "Pre 8.2", -destination-cluster must also be specified.

[-force | -f [true]] - Force

If specified, the delete proceeds even if it cannot clean up all artifacts of the relationship.

[-foreground | -w [true]] - Foreground Process

This specifies whether the operation runs as a foreground process. If this parameter is specified, the default setting is true (the operation runs in the foreground). When set to true, the command will not return until the process completes. This parameter is only applicable to relationships with "Relationship Capability" of "Pre 8.2".

Examples

To delete the SnapMirror relationship with the destination endpoint vs2.example.com:dept_eng_dp_mirror4, type the following command:

```
vs2.example.com::> snapmirror delete -destination-path vs2.example.com:dept_eng_dp_mirror4
```

For relationships with "Relationship Capability" of "Pre 8.2", to delete the SnapMirror relationship with the destination endpoint cluster2://vs2.example.com/dept_eng_dp_mirror4, type the following command:

```
cluster2::> snapmirror delete -destination-path cluster2://vs2.example.com/dept_eng_dp_mirror4
```
To delete the SnapMirror relationship with destination endpoint `dvs1.example.com`, type the following command:

```
cluster2::> snapmirror delete -destination-path dvs1.example.com:
```

Under PVR control to delete the synchronous SnapMirror Consistency Group relationship with the destination Consistency Group `cg_dst` in Vserver `vs2.example.com` and all item mappings, type the following command:

```
vs2.example.com::> snapmirror delete -destination-path vs2.example.com:/cg/cg_dst
```

Under PVR control to delete the item mapping between `lun3` on volume `srcvol` and `lun3` on volume `dstvol` in the SnapMirror synchronous Consistency Group relationship with the destination Consistency Group `cg_dst` in Vserver `vs2.example.com`, type the following command:

```
vs2.example.com::> snapmirror delete -destination-path vs2.example.com:/cg/cg_dst -cg-item-mappings /vol/srcvol/lun3:@/vol/dstvol/lun3
```

**snapmirror initialize**

Start a baseline transfer

**Availability:** This command is available to `cluster` and `Vserver` administrators at the `admin` privilege level.

**Description**

The `snapmirror initialize` command initializes the destination volume of a SnapMirror relationship. The command behaves differently between data protection (DP), extended data protection (XDP) and load-sharing (LS) relationships.

For data protection (DP) and extended data protection (XDP) relationships, the `snapmirror initialize` command initializes the destination volume.

For load-sharing (LS) relationships, the `snapmirror initialize` command initializes a new load-sharing mirror in an existing set of load-sharing mirrors. If the command finishes before the start of a scheduled or manual transfer of the set of load-sharing mirrors, the load-sharing mirror is up to date with the set of load-sharing mirrors; otherwise, the load-sharing mirror will be brought up to date at the next scheduled or manual transfer of the set of load-sharing mirrors.

The initial transfer to an empty destination volume is called a baseline transfer. During a baseline transfer for a data protection (DP) or extended data protection (XDP) relationship, the `snapmirror initialize` command takes a Snapshot copy on the source volume to capture the current image of the source volume. For data protection relationships, the `snapmirror initialize` command transfers all of the Snapshot copies up to and including the Snapshot copy created by it from the source volume to the destination volume. For extended data protection (XDP) relationships, the `snapmirror initialize` command behavior depends on the `snapmirror policy` associated with the relationship. If the policy type is `async-mirror` then depending on the rules in the policy it can transfer either all the Snapshot copies up to and including the Snapshot copy created by it or only the Snapshot copy created by it from the source volume to the destination volume. For extended data protection (XDP) relationships with policy type `vault` or `mirror-vault` the `snapmirror initialize` transfers only the Snapshot copy created by it.
After the `snapmirror initialize` command successfully completes, the last Snapshot copy transferred is made the exported Snapshot copy on the destination volume.

When an Infinite Volume SnapMirror relationship is initialized, the command will create any needed constituent volumes for the destination Infinite Volume. The Infinite Volume relationship will appear in the `snapmirror show` command output on the source cluster after it is initialized.

You can use the `snapmirror initialize` command to initialize a specific load-sharing mirror that is new to the set of load-sharing mirrors. An initialize of the new load-sharing mirror should bring it up to date with the other up-to-date destination volumes in the set of load-sharing mirrors.

**Note:** Using the `snapmirror initialize` command to initialize a set of load-sharing mirrors will not work. Use the `snapmirror initialize-ls-set` command to initialize a set of load-sharing mirrors.

If a SnapMirror relationship does not already exist, that is, the relationship was not created using the `snapmirror create` command, the `snapmirror initialize` command will implicitly create the SnapMirror relationship, with the same behaviors as described for the `snapmirror create` command before initializing the relationship. This implicit create feature is not supported for Infinite Volumes and Vservers.

This command is supported for SnapMirror relationships with the field "Relationship Capability" showing as either "8.2 and above" or "Pre 8.2" in the output of the `snapmirror show` command.

For relationships with "Relationship Capability" of "8.2 and above", you can track the progress of the operation using the `snapmirror show` command.

For relationships with "Relationship Capability" of "Pre 8.2", a job will be spawned to operate on the SnapMirror relationship, and the job id will be shown in the command output. The progress of the job can be tracked using the `job show` and `job history show` commands.

The `snapmirror initialize` command must be used from the destination Vserver or cluster.

**Parameters**

```
[-source-path | -S {<vserver:>[volume]> | <[[cluster://vserver/]]volume> | <[hostname://lun/]lun-name>}] - Source Path
```

Specifies the source endpoint of the SnapMirror relationship in one of two path formats. The normal format includes the names of the Vserver (vserver) and/or volume (volume). To support relationships with "Relationship Capability" of "Pre 8.2", a format which also includes the name of the cluster (cluster) is provided. The "Pre 8.2" format cannot be used when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above".

```
[-source-cluster <Cluster name>] - Source Cluster
```

Specifies the source cluster of the SnapMirror relationship. If this parameter is specified, the `-source-vserver` and `-source-volume` parameters must also be specified. This parameter is only applicable for relationships with "Relationship Capability" of "Pre 8.2". This parameter cannot be specified when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above".

```
[-source-vserver <vserver name>] - Source Vserver
```

Specifies the source Vserver of the SnapMirror relationship. For relationships with volumes as endpoints, if this parameter is specified, parameters `-source-volume` and for relationships with "Relationship Capability" of "Pre 8.2", `-source-cluster` must also be specified.

```
[-source-volume <volume name>] - Source Volume
```

Specifies the source volume of the SnapMirror relationship. If this parameter is specified, parameters `-source-vserver` and for relationships with "Relationship Capability" of "Pre 8.2", `-source-cluster` must also be specified.
{ -destination-path <[vserver:]volume>|<[cluster:]//vserver/volume>|<[hostname:]lun/lun-name> } - Destination Path

Specifies the destination endpoint of the SnapMirror relationship in one of two path formats. The normal format includes the names of the Vserver (vserver) and/or volume (volume). To support relationships with "Relationship Capability" of "Pre 8.2", a format which also includes the name of the cluster (cluster) is provided. The "Pre 8.2" format cannot be used when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above".

{ -destination-cluster <Cluster name> } - Destination Cluster

Specifies the destination cluster of the SnapMirror relationship. If this parameter is specified, parameters -destination-vserver and -destination-volume must also be specified. This parameter is only applicable for relationships with "Relationship Capability" of "Pre 8.2". This parameter cannot be specified when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above".

-destination-vserver <vserver name> - Destination Vserver

Specifies the destination Vserver of the SnapMirror relationship. For relationships with volumes as endpoints, if this parameter is specified, parameters -destination-volume and for relationships with "Relationship Capability" of "Pre 8.2", -destination-cluster must also be specified.

-destination-volume <volume name> - Destination Volume

Specifies the destination volume of the SnapMirror relationship. If this parameter is specified, parameters -destination-vserver and for relationships with "Relationship Capability" of "Pre 8.2", -destination-cluster must also be specified.

[-source-snapshot | -s <text>] - Source Snapshot

This optional parameter specifies the Snapshot copy that snapmirror initialize will use for the baseline transfer. For data protection (DP) relationships, the baseline transfer will include all of the Snapshot copies up to and including the specified Snapshot copy. For extended data protection (XDP) relationships, the snapmirror initialize command behavior depends on the snapmirror policy associated with the relationship. If the policy type is async-mirror then depending on the rules in the policy it can transfer either all the Snapshot copies up to and including the specified Snapshot copy or only the specified Snapshot copy from the source volume to the destination volume. For extended data protection (XDP) relationships with policy type vault or mirror-vault the snapmirror initialize transfers only the specified Snapshot copy. This parameter is not supported for relationships with "Relationship Capability" of "Pre 8.2". This parameter is not supported for Infinite Volume SnapMirror relationships.

[-type <snapmirrorType>] - Snapmirror Relationship Type

Specifies the type of SnapMirror relationship if a relationship is implicitly created. This parameter is the same as the one used in the snapmirror create command.

[-policy <sm_policy>] - SnapMirror Policy

This optional parameter designates the name of the SnapMirror policy which is associated with the SnapMirror relationship. If you do not designate a policy, the current policy will be retained. This parameter is not applicable to relationships with "Relationship Capability" of "Pre 8.2". This parameter is not supported by this operation for Infinite Volumes.

Note: You define and name a policy using the snapmirror policy create command.

[-throttle | -k <throttleType>] - Throttle (KB/sec)

This optional parameter limits the network bandwidth used for the initialize transfer. It sets the maximum rate (in Kbytes/sec) at which data can be transferred during the operation. If this parameter is not specified, the throttle value configured for the relationship with the snapmirror create or snapmirror modify commands will be used. To specify fully using the network bandwidth available, set the throttle value to unlimited or 0. The minimum throttle value is four Kbytes/sec, so if you specify a throttle value between 1 and 4, it will be treated as if you specified 4. The -throttle parameter does not affect load-sharing transfers...
and transfers for other relationships with "Relationship Capability" of "Pre 8.2" confined to a single cluster.

**[-transfer-priority {low|normal}] - Transfer Priority**

This optional parameter specifies the priority at which the transfer runs. The default value for this parameter is the value in the SnapMirror policy associated with this relationship. This parameter is not applicable to relationships with a "Relationship Capability" of "Pre 8.2".

**[-foreground | -w [true]} - Foreground Process**

This specifies whether the operation runs as a foreground process. If this parameter is specified, the default setting is true (the operation runs in the foreground). When set to true, the command will not return until the process completes. This parameter is only applicable to relationships with "Relationship Capability" of "Pre 8.2".

### Examples

To start the initial transfer for the SnapMirror relationship with the destination endpoint `vs2.example.com:dept_eng_dp_mirror2` after the relationship has been created with the `snapmirror create` command, type the following command:

```bash
vs2.example.com::> snapmirror initialize -destination-path
vs2.example.com:dept_eng_dp_mirror2
```

For relationships with "Relationship Capability" of "Pre 8.2", to start the initial transfer for the SnapMirror relationship with the destination endpoint `cluster2://vs2.example.com/dept_eng_dp_mirror2` after the relationship has been created with the `snapmirror create` command, type the following command:

```bash
cluster2::> snapmirror initialize -destination-path
cluster2://vs2.example.com/dept_eng_dp_mirror2
```

To create a data protection mirror relationship between the source endpoint `vs1.example.com:dept_mkt`, and the destination endpoint `vs2.example.com:dep_mkt_dp_mirror`, and start the initial transfer, type the following command:

```bash
vs2.example.com::> snapmirror initialize -destination-path
-vs.example.com2:dept_mkt_dp_mirror
-source-path vs1.example.com:dept_mkt
```

To create a data protection mirror relationship between the source endpoint `cluster1://vs1.example.com/dept_mkt`, and the destination endpoint `cluster2://vs2.example.com/dep_mkt_dp_mirror`, and start the initial transfer when the source cluster is running Data ONTAP 8.1 software, type the following command:

```bash
cluster2::> snapmirror initialize -destination-path
cluster2://vs2.example.com/dep_mkt_dp_mirror
-source-path cluster1://vs1.example.com/dept_mkt
```

To start the initial transfer for the Vserver SnapMirror relationship with destination endpoint `dvs1.example.com: after the relationship was created with the snapmirror create command, type the following command:

```bash
cluster2::> snapmirror initialize -destination-path
dvs1.example.com:
```

Under PVR control to create a SnapMirror synchronous Consistency Group relationship with the following attributes:

- It is between the source Consistency Group `cg_src` in Vserver `vs1.example.com`, and the destination Consistency Group `cg_dst` in Vserver `vs2.example.com`.
- It has item mappings between `lun1` and `lun2` on volume `srcvol` and `lun1` and `lun2` on volume `dstvol`.

510

Commands: Manual Page Reference
• It uses a policy named Sync that has a policy type of `sync-mirror` that the user has previously created.

and initialize it and bring it InSync, type the following command:

```
vs2.example.com::> snapmirror initialize -destination-path
   vs2.example.com:/cg/cg_dst -source-path
   vs1.example.com:/cg/cg_src -type XDP -policy Sync
   -cg-item-mappings /vol/srcvol/lun1:@/vol/dstvol/lun1,
                    /vol/srcvol/lun2:@/vol/dstvol/lun2
```

Under PVR control to initialize the relationship with destination Consistency Group `cg_dst` in Vserver `vs2.example.com` that has been created with the `snapmirror create` command and bring it InSync, type the following command:

```
vs2.example.com::> snapmirror initialize -destination-path
   vs2.example.com:/cg/cg_dst
```

**snapmirror initialize-Is-set**

Start a baseline load-sharing set transfer

**Availability:** This command is available to `cluster` and `Vserver` administrators at the `admin` privilege level.

**Description**

The `snapmirror initialize-Is-set` command initializes and updates a set of load-sharing mirrors. This command is usually used after the `snapmirror create` command is used to create a SnapMirror relationship for each of the destination volumes in the set of load-sharing mirrors. The initial transfers to empty load-sharing mirrors are baseline transfers done in parallel. During a baseline transfer Data ONTAP takes a Snapshot copy on the source volume to capture the current image of the source volume and transfers all of the Snapshot copies on the source volume to each of the destination volumes.

After the `snapmirror initialize-Is-set` command successfully completes, the last Snapshot copy transferred is made the exported Snapshot copy on the destination volumes.

The parameter that identifies the set of load-sharing mirrors is the source volume. Data and Snapshot copies are transferred from the source volume to all up-to-date destination volumes in the set of load-sharing mirrors.

Use the `snapmirror initialize` command to add and initialize a new destination volume to an existing set of load-sharing mirrors.

**Note:** Even if the load-sharing set only has one mirror, you still need to use the `snapmirror initialize-Is-set` command to initialize the set. The `snapmirror initialize` command can only be used to initialize a new destination volume, if the load-sharing set has already been initialized.
This command is not supported on Infinite Volume snapmirror relationships. This command is only supported for SnapMirror relationships with the field "Relationship Capability" showing as "Pre 8.2" in the output of the snapmirror show command.

Parameters

- **-source-path | -S {<[vserver:]>[volume]>|<[[cluster:]//vserver/]volume>|<[hostname:]//lun/lun-name>}** - Source Path
  Specifies the source endpoint of the SnapMirror relationship in one of two path formats. The normal format includes the names of the Vserver (vserver) and/or volume (volume). To support relationships with "Relationship Capability" of "Pre 8.2", a format which also includes the name of the cluster (cluster) is provided. The "Pre 8.2" format cannot be used when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above".

- **-source-cluster [Cluster name]** - Source Cluster
  Specifies the source cluster of the SnapMirror relationship. If this parameter is specified, the -source-vserver and -source-volume parameters must also be specified. This parameter is only applicable for relationships with "Relationship Capability" of "Pre 8.2". This parameter cannot be specified when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above".

- **-source-vserver <vserver name>** - Source Vserver
  Specifies the source Vserver of the SnapMirror relationship. For relationships with volumes as endpoints, if this parameter is specified, parameters -source-volume and for relationships with "Relationship Capability" of "Pre 8.2", -source-cluster must also be specified.

- **-source-volume <volume name>** - Source Volume
  Specifies the source volume of the SnapMirror relationship. If this parameter is specified, parameters -source-vserver and for relationships with "Relationship Capability" of "Pre 8.2", -source-cluster must also be specified.

- **[-foreground | -w [true]]** - Foreground Process
  This specifies whether the operation runs as a foreground process. If this parameter is specified, the default setting is true (the operation runs in the foreground). When set to true, the command will not return until the process completes. This parameter is only applicable to relationships with "Relationship Capability" of "Pre 8.2".

Examples

To initialize the group of load-sharing mirrors for the source endpoint //vs1.example.com/dept_eng, type the following command:

```
cluster1::> snapmirror initialize-ls-set -source-path
//vs1.example.com/dept_eng
```

snapmirror list-destinations

Display a list of destinations for SnapMirror sources

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The `snapmirror list-destinations` command displays information including the destination endpoints, the relationship status, and transfer progress, for SnapMirror relationships whose source endpoints are in the current Vserver if you are in a Vserver context, or the current cluster if you are in a cluster context.

The command might display several relationships that have the same source and destination endpoints, but have different relationship IDs. If this is the case, some of the information is stale. It corresponds to relationships that have been deleted on the destination Vserver or cluster, and have not been released yet on the source Vserver or source cluster.

The relationships and the information displayed are controlled by the parameters that you specify. If no parameters are specified, the command displays the following information associated with each SnapMirror relationship whose source endpoint is in the current Vserver if you are in a Vserver context, or the current cluster if you are in a cluster context:

- Source path
- Relationship Type
- Destination Path
- Relationship Status
- Transfer Progress
- Progress Last Updated
- Relationship ID

Note the following limitations on the information displayed by the `snapmirror list-destinations` command:

- The "Relationship Status" field is not valid after the node hosting the source volume joins the cluster quorum, until at least one transfer is performed on the SnapMirror relationship.
- "Transfer Progress" and "Progress Last Updated" fields are only valid if a Snapshot copy transfer is in progress.
- The "Relationship ID" field is not valid for Vserver SnapMirror relationships.

The `-instance` and `-fields` parameters are mutually exclusive and select the fields that are displayed. The `-instance` parameter if specified, displays detailed information about the relationships. The other parameters of the `snapmirror list-destinations` command, select the SnapMirror relationships for which the information is displayed.

Parameters

```
{ [-fields <fieldname>,...]  # If you specify the -fields <fieldname>,... parameter, the command only displays the fields that you have specified.

| [-instance]  # If you specify the -instance parameter, the command displays detailed information about all relationships selected.

{ [-source-path |-S <[vserver:][volume]>|<[[cluster://vserver/]]volume>|<[hostname:]/lun/lun-name>] } - Source Path

Selects SnapMirror relationships that have a matching source path name.
```
[-source-vserver <vserver name>] - Source Vserver
  Selects SnapMirror relationships that have a matching source Vserver name.

[-source-volume <volume name>] - Source Volume
  Selects SnapMirror relationships that have a matching source volume name.

[-destination-path (<!--vserver:/>vol/>|<!--cluster://vserver/>vol/>|<!--hostname:/lun/ lun-name-->)] - Destination Path
  Selects SnapMirror relationships that have a matching destination path name.

[-destination-vserver <vserver name>] - Destination Vserver
  Selects SnapMirror relationships that have a matching destination Vserver name.

[-destination-volume <volume name>] - Destination Volume
  Selects SnapMirror relationships that have a matching destination volume name.

[-relationship-id <UUID>] - Relationship ID
  Selects SnapMirror relationships that have a matching relationship identifier. This parameter is not supported for Vserver SnapMirror relationships.

[-type <snapmirrorType>] - Relationship Type
  Selects SnapMirror relationships that have a matching relationship type. Possible values are:
  • DP
  • XDP
  • RST

[-relationship-group-type {none|vserver|infinitevol|consistencygroup}] - Relationship Group Type
  Selects SnapMirror relationships that have a matching relationship group type. Possible values are:
  • none
  • vserver
  • infinitevol

[-policy-type {vault|async-mirror|mirror-vault}] - SnapMirror Policy Type
  Selects SnapMirror relationships that have a matching SnapMirror policy type. Possible values are:
  • async-mirror
  • vault
  • mirror-vault

[-status <mirror status>] - Relationship Status
  Selects SnapMirror relationships that have a matching relationship status. Possible values are:
  • Idle
  • Transferring

[-transfer-progress (<integer>[KB|MB|GB|TB|PB])] - Transfer Progress
  Selects SnapMirror relationships that have a matching transfer progress. This option is not supported for Infinite Volume SnapMirror relationships.

[-progress-last-updated <MM/DD HH:MM:SS>] - Timestamp of Last Progress Update
  Selects SnapMirror relationships that have a matching transfer progress last updated timestamp. This option is not supported for Infinite Volume SnapMirror relationships.
[-is-constituent {true|false}] - Constituent Relationship
Selects SnapMirror relationships that have a matching constituent condition. This parameter is not supported for VServer SnapMirror relationships.

[-source-volume-node <nodename>] - Source Volume Node Name
Selects SnapMirror relationships that have a matching source volume node name. This parameter is not supported for VServer SnapMirror relationships.

[-expand {true}] - Show Constituents of the Group
Specifies whether to display constituent relationships of Vserver SnapMirror relationships. By default, the constituents are not displayed.

### Examples

To display summary information about all relationships whose source endpoints are in the current cluster, type the following command:

```
class::> snapmirror list-destinations
```

<table>
<thead>
<tr>
<th>Source Path</th>
<th>Type</th>
<th>Destination Path</th>
<th>Status</th>
<th>Transfer Progress</th>
<th>Progress Last Updated</th>
<th>Relationship ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>vserver1.example.com:dp_s1</td>
<td>DP</td>
<td>vserver2.example.com:dp_d1</td>
<td>Idle</td>
<td>-</td>
<td>-</td>
<td>06b4327b-954f-11e1-af65-123478563412</td>
</tr>
<tr>
<td>vserver1.example.com:xdp_s1</td>
<td>XDP</td>
<td>vserver2.example.com:xdp_d1</td>
<td>Idle</td>
<td>-</td>
<td>-</td>
<td>a9c1db0b-954f-11e1-af65-123478563412</td>
</tr>
<tr>
<td>vserver2.example.com:dp_s1</td>
<td>DP</td>
<td>dvserver2.example.com:dp_s1</td>
<td>Idle</td>
<td>-</td>
<td>-</td>
<td>-</td>
</tr>
</tbody>
</table>

3 entries were displayed.

To display summary information about all relationships whose source endpoints are in the current Vserver, type the following command:

```
vserver1.example.com::> snapmirror list-destinations
```

<table>
<thead>
<tr>
<th>Source Path</th>
<th>Type</th>
<th>Destination Path</th>
<th>Status</th>
<th>Transfer Progress</th>
<th>Progress Last Updated</th>
<th>Relationship ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>vserver1.example.com:dp_s1</td>
<td>DP</td>
<td>vserver2.example.com:dp_d1</td>
<td>Idle</td>
<td>-</td>
<td>-</td>
<td>06b4327b-954f-11e1-af65-123478563412</td>
</tr>
<tr>
<td>vserver1.example.com:xdp_s1</td>
<td>XDP</td>
<td>vserver2.example.com:xdp_d1</td>
<td>Idle</td>
<td>-</td>
<td>-</td>
<td>a9c1db0b-954f-11e1-af65-123478563412</td>
</tr>
<tr>
<td>vserver2.example.com:dp_s1</td>
<td>DP</td>
<td>dvserver2.example.com:dp_s1</td>
<td>Idle</td>
<td>-</td>
<td>-</td>
<td>-</td>
</tr>
</tbody>
</table>

2 entries were displayed.

To display detailed information about SnapMirror relationships whose source endpoints are in the current Vserver, type the following command:

```
vserver1.example.com::> snapmirror list-destinations -instance
```

Source Path: vserver1.example.com:dp_s1
Destination Path: vserver2.example.com:dp_d1
Relationship Type: DP
Relationship Group Type: none
Relationship Status: Idle
Transfer Progress: -
Progress Last Updated: -
Source Volume Node: node1
Relationship ID: 06b4327b-954f-11e1-af65-123478563412

`snapmirror show` on page 538

## snapmirror modify

Modify a SnapMirror relationship

**Availability:** This command is available to `cluster` and `Vserver` administrators at the `admin` privilege level.

**Description**

The `snapmirror modify` command allows you to change one or more properties of SnapMirror relationships. The key parameter that identifies any SnapMirror relationship is the destination endpoint. The endpoint can be a Vserver or a volume.

For load-sharing mirrors, a change to a property affects all of the SnapMirror relationships in the set of load-sharing mirrors. Destination volumes in a set of load-sharing mirrors do not have individual property settings.

Changes made by the `snapmirror modify` command do not take effect until the next manual or scheduled update of the SnapMirror relationship. Changes do not affect updates that have started and have not finished yet.

This command is supported for SnapMirror relationships with the field "Relationship Capability" showing as either "8.2 and above" or "Pre 8.2" in the output of the `snapmirror show` command.

The `snapmirror modify` command must be used from the destination Vserver or cluster.

**Parameters**

```
{-source-path | -S \{<vserver::volume>|<[[cluster::vserver::volume]|<[[hostname::lun/ lwn-name>])
```

- **Source Path**

  Specifies the source endpoint of the SnapMirror relationship in one of two path formats. The normal format includes the names of the Vserver (vserver) and/or volume (volume). To support relationships with "Relationship Capability" of "Pre 8.2", a format which also includes the name of the cluster (cluster) is provided. The "Pre 8.2" format cannot be used when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above".

```
[-source-cluster <Cluster name>]
```

- **Source Cluster**

  Specifies the source cluster of the SnapMirror relationship. If this parameter is specified, the `-source-vserver` and `-source-volume` parameters must also be specified. This parameter is only applicable for relationships with "Relationship Capability" of "Pre 8.2". This parameter cannot be specified when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above".

```
[-source-vserver <vserver name>]
```

- **Source Vserver**

  Specifies the source Vserver of the SnapMirror relationship. For relationships with volumes as endpoints, if this parameter is specified, parameters `-source-volume` and for relationships with "Relationship Capability" of "Pre 8.2", `-source-cluster` must also be specified.
[-source-volume <volume name>] - Source Volume

Specifies the source volume of the SnapMirror relationship. If this parameter is specified, parameters -
source-vserver and for relationships with "Relationship Capability" of "Pre 8.2", -source-
cluster must also be specified.

{-destination-path {<vserver:volume>|<cluster:vserver:volume>|<hostname:lun/lun-name>}} - Destination Path

Specifies the destination endpoint of the SnapMirror relationship in one of two path formats. The normal
format includes the names of the Vserver (vserver) and/or volume (volume). To support relationships with
"Relationship Capability" of "Pre 8.2", a format which also includes the name of the cluster
(cluster) is provided. The "Pre 8.2" format cannot be used when operating in a Vserver context on
relationships with "Relationship Capability" of "8.2 and above".

[-destination-cluster <Cluster name>] - Destination Cluster

Specifies the destination cluster of the SnapMirror relationship. If this parameter is specified, parameters -
destination-vserver and -destination-volume must also be specified. This parameter is only
applicable for relationships with "Relationship Capability" of "Pre 8.2". This parameter cannot be
specified when operating in a Vserver context on relationships with "Relationship Capability" of "8.2
and above".

-destination-vserver <vserver name> - Destination Vserver

Specifies the destination Vserver of the SnapMirror relationship. For relationships with volumes as endpoints,
if this parameter is specified, parameters -destination-volume and for relationships with
"Relationship Capability" of "Pre 8.2", -destination-cluster must also be specified.

-destination-volume <volume name> - Destination Volume

Specifies the destination volume of the SnapMirror relationship. If this parameter is specified, parameters -
destination-vserver and for relationships with "Relationship Capability" of "Pre 8.2", -destination-cluster must also be specified.

[-vserver <vserver name>] - Managing Vserver

If this optional parameter is specified, designates the managing Vserver. The managing Vserver is authorized
to use some snapmirror commands to manage the SnapMirror relationship. The -vserver option is currently
a reserved option.

[-schedule <text>] - SnapMirror Schedule

This optional parameter designates the name of the schedule which is used to update the SnapMirror
relationship. If you do not designate a schedule, updates are not scheduled, so you must update the SnapMirror
relationship manually using the snapmirror update command or, in the case of a set of load-sharing
mirrors, using the snapmirror update-ls-set command.

Note: You define and name a schedule using the job schedule cron create command.

The schedules associated with an Infinite Volume SnapMirror relationship should not have an interval
shorter than hourly.

[-policy <sm_policy>] - SnapMirror Policy

This optional parameter designates the name of the snapmirror policy which is associated with the SnapMirror
relationship. If you do not designate a policy, the current policy will be retained. This parameter is not
applicable to relationships with "Relationship Capability" of "Pre 8.2".

Note: You define and name a policy using the snapmirror policy create command.

[-tries <unsigned32_or_unlimited>] - Tries Limit

This optional parameter specifies the maximum number of times to attempt each manual or scheduled transfer
for a SnapMirror relationship. The default is eight times. The -tries parameter can be set to 0 to disable
manual and scheduled updates for the SnapMirror relationship. This parameter is only applicable to
relationships with "Relationship Capability" of "Pre 8.2". For relationships with "8.2 and above" capability, the tries limit is controlled by the value of tries in the SnapMirror policy which is associated with the relationship.

[-throttle | -k <throttleType>] - Throttle (KB/sec)

This optional parameter limits the network bandwidth used for transfers. It configures for the relationship the maximum rate (in Kbytes/sec) at which data can be transferred. If no throttle is configured, by default the SnapMirror relationship fully utilizes the network bandwidth available. You can also configure the relationship to fully use the network bandwidth available by explicitly setting the throttle to unlimited or 0. The minimum effective throttle value is four Kbytes/sec, so if you specify a throttle value between 1 and 4, it will be treated as 4. The -throttle parameter does not affect load-sharing mirrors and other SnapMirror relationships with "Relationship Capability" of "Pre 8.2" confined to a single cluster.

[-foreground | -w [true]] - Foreground Process

This specifies whether the operation runs as a foreground process. If this parameter is specified, the default setting is true (the operation runs in the foreground). When set to true, the command will not return until the process completes. This parameter is only applicable to relationships with "Relationship Capability" of "Pre 8.2".

**Examples**

To change the schedule to halfhour for the SnapMirror relationship with the destination endpoint vs2.example.com:dept_eng_dp_mirror2, type the following command:

```
vs2.example.com::> snapmirror modify -destination-path vs2.example.com:dept_eng_dp_mirror2 -schedule halfhour
```

For relationships with "Relationship Capability" of "Pre 8.2", to change the schedule to halfhour for the SnapMirror relationship with the destination endpoint cluster2://vs2.example.com/dept_eng_dp_mirror2, type the following command:

```
cluster2::> snapmirror modify -destination-path cluster2://vs2.example.com/dept_eng_dp_mirror2 -schedule halfhour
```

To change the schedule to halfhour for the Vserver SnapMirror relationship with destination endpoint dvs1.example.com:, type the following command:

```
cluster2::> snapmirror modify -destination-path dvs1.example.com: -schedule halfhour
```

To change the policy associated with the synchronous SnapMirror Consistency Group relationship with the destination Consistency Group cg_dst in Vserver vs2.example.com to the policy Sync2, type the following command:

```
vs2.example.com::> snapmirror modify -destination-path vs2.example.com:/cg/cg_dst -policy Sync2
```

snapmirror promote

Promote the destination to read-write

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description

The snapmirror promote command performs a failover to the destination volume of a SnapMirror relationship. This command changes the destination volume from a read-only volume to a read-write volume and makes the destination volume assume the identity of the source volume. The command then destroys the original source volume. The destination volume must be a load-sharing volume. Note that you can promote a load-sharing volume that has been left in read-write state by a previously failed promote operation.

Client accesses are redirected from the original source volume to the promoted destination volume. The view clients see on the promoted destination volume is the latest transferred Snapshot copy, which might lag behind the view clients had of the original source volume before the promote.

The SnapMirror relationship is always deleted as part of the promotion process.

It is possible that the original source volume is the source of multiple SnapMirror relationships. For such a configuration, the promoted destination volume becomes the new source volume of the other SnapMirror relationships.

This command is only supported for SnapMirror relationships with the field "Relationship Capability" showing as "Pre 8.2" in the output of the snapmirror show command.

The snapmirror promote command fails if a SnapMirror transfer is in progress for any SnapMirror relationship with "Relationship Capability" of "Pre 8.2" involving the original source volume. It does not fail if a SnapMirror transfer is in progress for a relationship with "Relationship Capability" of "8.2 and above".

This command is not supported on Infinite Volume snapmirror relationships.

Parameters

{{[-source-path | -S (\<[vserver:]\>[volume]|<[[cluster://vserver/]volume>|<\[hostname:/lun/\>lun-name>>]}  - Source Path

Specifies the source endpoint of the SnapMirror relationship in one of two path formats. The normal format includes the names of the Vserver (vserver) and/or volume (volume). To support relationships with "Relationship Capability" of "Pre 8.2", a format which also includes the name of the cluster (cluster) is provided. The "Pre 8.2" format cannot be used when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above".

|[-source-cluster <Cluster name>] - Source Cluster

Specifies the source cluster of the SnapMirror relationship. If this parameter is specified, the -source-vserver and -source-volume parameters must also be specified. This parameter is only applicable for relationships with "Relationship Capability" of "Pre 8.2". This parameter cannot be specified when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above".

|[-source-vserver <vserver name>] - Source Vserver

Specifies the source Vserver of the SnapMirror relationship. For relationships with volumes as endpoints, if this parameter is specified, parameters -source-volume and for relationships with "Relationship Capability" of "Pre 8.2", -source-cluster must also be specified.

|[-source-volume <volume name>] - Source Volume

Specifies the source volume of the SnapMirror relationship. If this parameter is specified, parameters -source-vserver and for relationships with "Relationship Capability" of "Pre 8.2", -source-cluster must also be specified.
-destination-path <[vserver:]/[volume]>|<[cluster://vserver]/volume>|<[hostname://lun/]
lun-name>} - Destination Path

Specifies the destination endpoint of the SnapMirror relationship in one of two path formats. The normal format includes the names of the Vserver (vserver) and/or volume (volume). To support relationships with "Relationship Capability" of "Pre 8.2", a format which also includes the name of the cluster (cluster) is provided. The "Pre 8.2" format cannot be used when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above".

[-destination-cluster <Cluster name>] - Destination Cluster

Specifies the destination cluster of the SnapMirror relationship. If this parameter is specified, parameters -destination-vserver and -destination-volume must also be specified. This parameter is only applicable for relationships with "Relationship Capability" of "Pre 8.2". This parameter cannot be specified when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above".

-destination-vserver <vserver name> - Destination Vserver

Specifies the destination Vserver of the SnapMirror relationship. For relationships with volumes as endpoints, if this parameter is specified, parameters -destination-volume and for relationships with "Relationship Capability" of "Pre 8.2", -destination-cluster must also be specified.

-destination-volume <volume name> - Destination Volume

Specifies the destination volume of the SnapMirror relationship. If this parameter is specified, parameters -destination-vserver and for relationships with "Relationship Capability" of "Pre 8.2", -destination-cluster must also be specified.

[-force | -f [true]] - Force

If this parameter is specified, the command proceeds without prompting for confirmation.

Examples

To promote a mirror named dept_eng_ls_mirror1 to be the source read-write volume for mirroring and client access, type the following command:

```
cluster1::> snapmirror promote -destination-path
//vsl.example.com/dept_eng_ls_mirror1
-destination-vserver //vsl.example.com/dept_eng
-source-path //vsl.example.com/dept_eng -f true
```

snapmirror quiesce

Disable future transfers

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description

The snapmirror quiesce command disables future transfers for a SnapMirror relationship. If there is no transfer in progress, the relationship becomes "Quiesced".

If there is a transfer in progress, it is not affected, and the relationship becomes "Quiescing" until the transfer completes. If the current transfer aborts, it will be treated like a future transfer and will not restart.

If applied to a load-sharing (LS) SnapMirror relationship, all the relationships in the load-sharing set will be quiesced.

When a SnapMirror relationship is quiesced, it remains quiesced across reboots and fail-overs.
This command is supported for SnapMirror relationships with the field "Relationship Capability" showing as either "8.2 and above" or "Pre 8.2" in the output of the snapmirror show command.

The snapmirror quiesce command must be used from the destination Vserver or cluster.

The relationship must exist on the destination Vserver or cluster. When issuing snapmirror quiesce, you must specify the destination endpoint. The specification of the source endpoint of the relationship is optional.

**Parameters**

```
[-source-path | -S {<[vserver:]volume>|<[cluster://vserver/]volume>|<[hostname:/lun/]
lun-name}>] - Source Path

Specifies the source endpoint of the SnapMirror relationship in one of two path formats. The normal format includes the names of the Vserver (vserver) and/or volume (volume). To support relationships with "Relationship Capability" of "Pre 8.2", a format which also includes the name of the cluster (cluster) is provided. The "Pre 8.2" format cannot be used when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above".

[-source-cluster <Cluster name>] - Source Cluster

Specifies the source cluster of the SnapMirror relationship. If this parameter is specified, the -source-vserver and -source-volume parameters must also be specified. This parameter is only applicable for relationships with "Relationship Capability" of "Pre 8.2". This parameter cannot be specified when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above".

[-source-vserver <vserver name>] - Source Vserver

Specifies the source Vserver of the SnapMirror relationship. For relationships with volumes as endpoints, if this parameter is specified, parameters -source-volume and for relationships with "Relationship Capability" of "Pre 8.2", -source-cluster must also be specified.

[-source-volume <volume name>] - Source Volume

Specifies the source volume of the SnapMirror relationship. If this parameter is specified, parameters -source-volume and for relationships with "Relationship Capability" of "Pre 8.2", -source-cluster must also be specified.

[-destination-path {<[vserver:]volume>|<[cluster://vserver/]volume>|<[hostname:/lun/]
lun-name}>] - Destination Path

Specifies the destination endpoint of the SnapMirror relationship in one of two path formats. The normal format includes the names of the Vserver (vserver) and/or volume (volume). To support relationships with "Relationship Capability" of "Pre 8.2", a format which also includes the name of the cluster (cluster) is provided. The "Pre 8.2" format cannot be used when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above".

[-destination-cluster <Cluster name>] - Destination Cluster

Specifies the destination cluster of the SnapMirror relationship. If this parameter is specified, parameters -destination-vserver and -destination-volume must also be specified. This parameter is only applicable for relationships with "Relationship Capability" of "Pre 8.2". This parameter cannot be specified when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above".

-destination-vserver <vserver name> - Destination Vserver

Specifies the destination Vserver of the SnapMirror relationship. For relationships with volumes as endpoints, if this parameter is specified, parameters -destination-volume and for relationships with "Relationship Capability" of "Pre 8.2", -destination-cluster must also be specified.

-destination-volume <volume name> - Destination Volume

Specifies the destination volume of the SnapMirror relationship. If this parameter is specified, parameters -destination-vserver and for relationships with "Relationship Capability" of "Pre 8.2", -destination-cluster must also be specified.
### Examples

To quiesce the SnapMirror relationship with the destination endpoint `vs2.example.com:dept_eng_mirror2`, type the following command:

```bash
vs2.example.com::> snapmirror quiesce -destination-path vs2.example.com:dept_eng_mirror2
```

For relationships with "Relationship Capability" of "Pre 8.2", to quiesce the SnapMirror relationship with the destination endpoint `cluster2://vs2.example.com/dept_eng_mirror2`, type the following command:

```bash
cluster2::> snapmirror quiesce -destination-path cluster2://vs2.example.com/dept_eng_mirror2
```

To quiesce the Vserver SnapMirror relationship with the destination endpoint `dvs1.example.com:`, type the following command:

```bash
cluster2::> snapmirror quiesce -destination-path dvs1.example.com:
```

Under PVR control to quiesce the synchronous SnapMirror Consistency Group relationship with the destination Consistency Group `cg_dst` in Vserver `vs2.example.com`, type the following command:

```bash
vs2.example.com::> snapmirror quiesce -destination-path vs2.example.com:/cg/cg_dst
```

### snapmirror release

Remove source information for a SnapMirror relationship

**Availability:** This command is available to cluster and Vserver administrators at the `admin` privilege level.

**Description**

The `snapmirror release` command removes the relationship information from the source Vserver. The command also removes any Snapshot copy owner tags and any Snapshot copies which were created for the specified relationship from the source volumes. It does not destroy any volumes or Vservers. This command must be used from the source Vserver or cluster.

You can use the `snapmirror list-destinations` command to display source Vservers' relationship information. This information is populated during the first SnapMirror transfer, not when the `snapmirror create` command is issued.

This command is not supported for SnapMirror relationships with the field "Relationship Capability" showing as "Pre 8.2" in the output of the `snapmirror show` command.

The `snapmirror release` operation fails if a SnapMirror transfer for the SnapMirror relationship is in a data phase of the transfer.
Parameters

\[-source-path | -S \{<vserver:[volume]>|<[[cluster://vserver/]]volume>|<hostname:/lun/lun-name>\}\] - Source Path

Specifies the source endpoint of the SnapMirror relationship in one of two formats. The normal format includes the names of the Vserver (vserver), and/or volume (volume). A format which also includes the name of the cluster (cluster) is also provided for consistency with other snapmirror commands. The form of the pathname which includes the cluster name cannot be used when operating in a Vserver context.

\[-source-vserver <vserver name>\] - Source Vserver

Specifies the source Vserver of the SnapMirror relationship. For relationships with volumes as endpoints, if this parameter is specified, parameter -source-volume must also be specified.

\[-source-volume <volume name>\] - Source Volume

Specifies the source volume of the SnapMirror relationship. If this parameter is specified, parameter -source-vserver must also be specified.

\{-destination-path \{<vserver:[volume]>|<[[cluster://vserver/]]volume>|<hostname:/lun/lun-name>\}\] - Destination Path

Specifies the destination endpoint of the SnapMirror relationship in one of two formats. The normal format includes the names of the Vserver (vserver), and/or volume (volume). A format which also includes the name of the cluster (cluster) is also provided for consistency with other snapmirror commands. The form of the pathname which includes the cluster name cannot be used when operating in a Vserver context.

\[-destination-vserver <vserver name>\] - Destination Vserver

Specifies the destination Vserver of the SnapMirror relationship. For relationships with volumes as endpoints, if this parameter is specified, parameter -destination-volume must also be specified.

\[-destination-volume <volume name>\] - Destination Volume

Specifies the destination volume of the SnapMirror relationship. If this parameter is specified, parameter -destination-vserver must also be specified.

\[-relationship-info-only [true]\] - Remove relationship info only (skip cleanup of snapshots)

If this parameter is specified, the cleanup of Snapshot copies is bypassed and only the source relationship information is removed. It is recommended to specify this parameter only when the source volume is not accessible.

\[-relationship-id <UUID>\] - Relationship ID

This optional parameter specifies the relationship identifier of the relationship. It must be specified when information for more than one relationship with the same source and destination paths is present. This parameter is not supported for Vserver SnapMirror relationships.

\[-force | -f [true]\] - Force

If this parameter is specified, the command proceeds without prompting for confirmation.

Examples

To release the source information for the SnapMirror relationship with the destination endpoint

\nvs2.example.com:dept_eng_dp_mirror4\n\ntype the following command:

\nvs1.example.com::> snapmirror release
-destination-path vs2.example.com:dept_eng_dp_mirror4\n\nTo release the source information for the SnapMirror relationship with the destination endpoint

\nvs2.example.com:dept_eng_dp_mirror4\n\ntype the following command:
To release the source information for the SnapMirror relationship with the destination endpoint `dvs1.example.com:`, type the following command:

```
cluster1::> snapmirror release
  -destination-path dvs1.example.com:
```

Under PVR control to release the source information for the synchronous SnapMirror Consistency Group relationship with the destination Consistency Group `cg_dst` in Vserver `vs2.example.com`, type the following command:

```
vs2.example.com::> snapmirror release
  -destination-path vs2.example.com:/cg/cg_dst
```

Under PVR control to release just the source information but not remove the Snapshot copies that might be needed for a subsequent resync for the synchronous SnapMirror Consistency Group relationship with the destination Consistency Group `cg_dst` in Vserver `vs2.example.com`, type the following command:

```
vs2.example.com::> snapmirror relese
  -destination-path vs2.example.com:/cg/cg_dst
  -relationship-info-only true
```

### snapmirror restore

Restore a Snapshot copy from a source volume to a destination volume

**Availability:** This command is available to cluster and Vserver administrators at the `admin` privilege level.

**Description**

The `snapmirror restore` command restores the entire contents of a Snapshot copy or one or more files or LUNs of a Snapshot copy from one volume to another volume.

The source of the restore can be a volume that is:

- the destination volume of a extended data protection (XDP) relationship
- the destination volume of a data protection (DP) relationship with "Relationship Capability" of "8.2 and above"
- a data-protection volume which is not the destination endpoint of any SnapMirror relationship
- a read-write volume.

The following volumes cannot be used as either the source nor destination volume of a restore:

- a volume that is the source or destination endpoint of a SnapMirror load-sharing relationship.
A SnapMirror relationship of type RST is created from the source volume to the destination volume by the `snapmirror restore` command. This relationship lasts for the duration of the restore operation and is deleted when the command completes successfully.

The following paragraphs describe the behavior when restoring the entire contents of a Snapshot copy to a destination volume.

By default the `snapmirror restore` will copy the latest Snapshot copy from the source volume to the destination volume. A specific Snapshot copy can be selected with the `-source-snapshot` parameter.

Any quota rules defined for the destination volume are deactivated prior to restoring the entire contents of a Snapshot copy. Run the command `volume quota modify -vserver destination-volume-vserver -volume destination-volume-name -state on` to reactivate quota rules after the entire contents of the Snapshot copy have been restored.

If the destination volume is an empty data protection volume, the `snapmirror restore` command performs a baseline restore. For a baseline restore the following steps are performed:

- Create the RST SnapMirror relationship.
- The entire contents of the Snapshot copy selected to be restored are copied to the active file system of the destination volume.
- The destination volume is made read-write.
- The RST SnapMirror relationship is deleted.

If the destination volume is a read-write volume, an incremental restore is performed. The incremental restore fails if it cannot find a common Snapshot copy between the source and destination volumes. Restoring a Snapshot copy to an empty read-write volume is not supported.

An incremental restore preserves all Snapshot copies on the destination volume but does not preserve changes to the active file system since the latest Snapshot copy. To preserve changes to the destination volume since the latest Snapshot copy use the `volume snapshot create` command. Restore is a disruptive operation so client access of the destination volume is not advised for the duration of the operation.

For an incremental restore the following steps are performed:

- Create the RST SnapMirror relationship.
- The active file system of the destination volume is reverted to the latest Snapshot copy on the destination volume and the destination volume is made read-only.
- This Snapshot copy is the exported Snapshot copy and it is the view to which clients are redirected when accessing the destination volume.
- The contents of the Snapshot copy selected to be restored are copied to the active file system of the destination volume.
- The destination volume is made read-write.
- The RST SnapMirror relationship is deleted.

If `snapmirror restore` fails or is aborted, the RST relationship remains. Use the `snapmirror show` command with the destination volume name to display the reason for the error. An EMS is also generated when a failure occurs. There are two options to recover when restore fails or is aborted:

- Take corrective action suggested by the EMS and reissue the original command.
- Use the original command with `-clean-up-failure` to cancel the request.

When specifying `-clean-up-failure` to cancel an incremental restore request, the following steps are performed:
• If the Snapshot copy has not been restored to the destination volume, all data copied to the active file system by `snapmirror restore` to the destination volume is reverted.

• The destination volume is made read-write.

• The `RST` SnapMirror relationship is deleted.

When specifying `--clean-up-failure` to cancel a baseline restore request, the following steps are performed:

• If the Snapshot copy has been restored to the destination volume, the volume is made read-write.

• The `RST` SnapMirror relationship is deleted.

The following paragraphs describe the behavior and requirements when restoring one or more files or LUNs to the destination volume.

The destination volume must be a read-write volume. Restoring files or LUNs to a data protection volume is not supported. When restoring files or LUNs the source and destination volumes are not required to have a common Snapshot copy. If a common Snapshot copy exists, an incremental restore is performed for those files or LUNs being restored which exist in the common Snapshot copy.

The contents of the files or LUNs to which data is being restored on the destination volume are not preserved by this command. To preserve the contents of the destination files or LUNs, create a Snapshot copy on the destination volume prior to running this command. Client I/O is not allowed to a file or LUN to which data is being restored on the destination volume.

The `--source-snapshot` parameter is required when restoring files or LUNs. It identifies the Snapshot copy on the source volume from which the files or LUNs to be restored are copied. If all files or LUNs to be restored do not exist in this Snapshot copy the command fails.

The source path for each file or LUN being restored is required. The source path of a file or LUN is from the root of the source Snapshot copy of the source volume. The file is restored to the same path on the destination volume unless an optional destination path is specified. The destination path is from the root of the destination volume. If a file or LUN to which data is being restored on the destination volume does not exist, the file or LUN is created. If any directory in the path of the file or LUN being restored does not exist on the destination volume, the command fails. Overwriting the contents of an existing file with the contents of a different file or overwriting the contents of an existing LUN with the contents of a different LUN is supported. Overwriting a file with a LUN or a LUN with a file is not supported. Client I/O is not allowed to all files and LUNs to which data is being restored on the destination volume.

If quota rules have been defined for the destination volume, resource usage is updated during file restore, but limits of quota rules are not enforced. Therefore, resource limits might be exceeded during a file restore.

Multiple concurrent `snapmirror restore` commands, restoring one or more files or LUNs to the same destination volume, are not supported. The destination volume of a `snapmirror restore` to which one or more file or LUNs are being restored, can simultaneously be the source volume of a `snapmirror update`.

For a file or LUN restore the following steps are performed:

• Create the `RST` SnapMirror relationship.

• If any file or LUN being restored does not exist on the destination volume, create all such files or LUNs.

• Prevent client I/O to files or LUNs to which data is being restored on the destination volume.

• Revoke locks and space reservations held by NAS clients for files being restored.

• Copy the contents of all source files or LUNs to the corresponding file or LUN on the destination volume.

• Allow client I/O to files or LUNs to which data has been restored on the destination volume.

• Delete the `RST` SnapMirror relationship.

**Note:** Some file restore operations require a Snapshot copy to be created. This Snapshot copy is temporary, it is deleted before the operation completes.
Since client I/O is not allowed to files or LUNs being restored, client I/O to files or LUNs being restored should be quiesced. Mapped LUNs remain mapped throughout the operation. SAN clients do not need to rediscover a mapped LUN that has been restored.

If `snapmirror restore` fails or is aborted, the RST relationship remains. Use the `snapmirror show` command with the destination volume to display the reason for the error. An EMS is also generated when a failure occurs. There are two options to recover when restore fails or is aborted:

- Take corrective action suggested by the EMS and reissue the original command.
- Use `snapmirror restore -clean-up-failure` along with specifying the destination volume to cancel the request.

When specifying `-clean-up-failure` to cancel a file restore request, the following steps are performed:

- Any files to which Client I/O is not allowed are removed.
- Any Snapshot copy created for use during a file restore operation is deleted.
- The RST SnapMirror relationship is deleted.

**Note:** LUNs to which Client I/O is not allowed remain. For LUNs to which client I/O is not allowed, do one of the following:

- Use the `snapmirror restore` command to restore data to the LUN. Once the command completes successfully, client I/O to the LUN is allowed.
- Delete the LUN using the `lun delete` command with the `-force-fenced` parameter.

The `snapmirror restore` command must be used from the destination Vserver or cluster.

**Parameters**

```
{-source-path | -S <[vserver]:[volume]> | <[cluster://vserver/]:volume>|<[hostname:/]lun/lun-name>} - Source Path
```

Specifies the source endpoint in one of two formats. The basic format includes the names of the Vserver (vserver) and volume (volume). A format which also includes the name of the cluster (cluster) is supported for consistency with other `snapmirror` commands. The form of the pathname which includes the cluster name is not valid when operating in a Vserver context.

```
[-source-cluster <Cluster name>] - Source Cluster
```

Specifies the cluster in which the source volume resides. This parameter is not needed; it is provided for consistency with other `snapmirror` commands. If this parameter is specified, the `-source-vserver` and `-source-volume` parameters must also be specified. This parameter is not valid when operating in a Vserver context.

```
[-source-vserver <vserver name>] - Source Vserver
```

Specifies the source Vserver of the SnapMirror relationship. If this parameter is specified, the `-source-volume` parameter must also be specified.

```
[-source-volume <volume name>]] - Source Volume
```

Specifies the source volume of the SnapMirror relationship. If this parameter is specified, the `-source-vserver` parameter must also be specified.

```
{ -destination-path <[vserver]:[volume]> | <[cluster://vserver/]:volume>|<[hostname:/]lun/lun-name>} - Destination Path
```

Specifies the destination endpoint in one of two formats. The basic format includes the names of the Vserver (vserver) and volume (volume). A format that also includes the name of the cluster (cluster) is supported for consistency with other `snapmirror` commands. The form of the pathname which includes the cluster name is not valid when operating in a Vserver context.
[[-destination-cluster <Cluster name>] - Destination Cluster

Specifies the cluster in which the destination volume resides. This parameter is not needed; it is provided for consistency with other snapmirror commands. If this parameter is specified, the -destination-vserver and -destination-volume parameters must also be specified. This parameter is not valid when operating in a Vserver context. This parameter is only applicable for relationships with "Relationship Capability" of "Pre 8.2".

-destination-vserver <vserver name> - Destination Vserver

Specifies the destination Vserver. If this parameter is specified, the -destination-volume parameter must also be specified.

-destination-volume <volume name> - Destination Volume

Specifies the destination volume. If this parameter is specified, the -destination-vserver parameter must also be specified.

[-source-snapshot | -s <text>] - Source Snapshot

When restoring the entire contents of a Snapshot copy, this optional parameter identifies the Snapshot copy to be restored from the source volume to the destination volume. The default value is the latest snapshot on the source volume. When restoring one or more files or LUNs from a Snapshot copy, this parameter is required.

[-throttle | -k <throttleType>] - Throttle (KB/sec)

This optional parameter limits the network bandwidth used for the restore transfer when the source and destination volumes belong to different clusters. It sets the maximum rate (in Kbytes/sec) at which data can be transferred between the clusters during the operation. To specify fully using the network bandwidth available between the clusters, set the throttle value to unlimited or 0. The minimum throttle value is four Kbytes/sec, so if you specify a throttle value between 1 and 4, it will be treated as if you specified 4.

[-transfer-priority {low|normal}] - Transfer Priority

This optional parameter specifies the priority at which the transfer runs. The default value for this parameter is normal.

[-disable-storage-efficiency [true]] - Disable Storage Efficient Transfer

The default behavior of restore is to preserve storage efficiency when possible. Use this optional parameter to turn off storage efficiency for data transferred over the wire and written to the destination volume.

[-clean-up-failure [true]] - Clean up after Failure

Use this optional parameter to recover from an aborted or failed restore operation. Any temporary RST relationship is removed from the destination Vserver. An attempt is made to remove any temporary RST relationship from the source Vserver. If cleaning up an incomplete restore of the entire contents of a Snapshot copy and the destination volume was read-write prior to the failed or aborted restore operation, it is converted back to read-write if necessary, while removing all data transferred or copied during the restore operation. If cleaning up an incomplete restore of one or more files or LUNs of a Snapshot copy, any file to which client I/O is not allowed is deleted.

[-tries <unsigned32_or_unlimited>] - Tries Limit

Specifies the total number of attempts to transfer data in cases where a transfer is interrupted by an error that SnapMirror can recover from. The value of this parameter must be a positive integer or unlimited.

[-force | -f [true]] - Force

If this parameter is specified, the command proceeds without prompting for confirmation.

[-file-list <<source path>,[@<destination path>],...] - File List

Specifies the files or LUNs to be restored. The list can contain specifications for up to 8 files or LUNs. Specification for each file or LUN consists of a source_path and an optional destination_path, and is of the form 'source_path[@destination_path]'. source_path is required and is the path of the file from the source Snapshot copy, e.g. /dira/file1 or /lun1. The source path does not include the Snapshot name nor the source volume name. The path to each file to be restored in the active file system of the destination volume is the same as the path specified by source_path, unless an optional destination_path is specified.
destination_path begins with the @ symbol followed by the path of the file from the root of the active file system of the destination volume, e.g. @/file1 or @/dira/lun1. Each source_path and destination_path is a separate entity in the list of paths. A destination_path is associated with the source_path that immediately precedes it. If this parameter is specified, -source-snapshot must also be specified. Examples:

| /dira/file1 |
| /dira/file1,@/dirb/file2 |
| /dira/file1,@/dirb/file2,/dirc/file3 |

[-use-network-compression [true]] - Use Network Compression

Use this optional parameter to use network compression for data transfer over the wire.

**Examples**

The following example does an incremental restore between the restore source volume vs2.example.com:dept_eng_dp_mirror2 and the restore destination volume vs1.example.com:dept_eng:

```
vs1.example.com::> snapmirror restore
   -destination-path vs1.example.com:dept_eng
   -source-path vs2.example.com:dept_eng_dp_mirror2
   -source-snapshot snap3
Warning: All data newer than Snapshot copy snap6 on volume vs1.example.com:dept_eng will be deleted.
Do you want to continue? {y|n}: y
[Job 34] Job is queued: snapmirror restore from source vs2.example.com:dept_eng_dp_mirror2 for the snapshot snap3.
vs1.example.com::>
```

The following example restores /file3 from the source Snapshot copy snap3 on the source volume vs2.example.com:dept_eng_dp_mirror2 to the active file system of the restore destination volume vs1.example.com:dept_eng:

```
vs1.example.com::> snapmirror restore
   -destination-path vs1.example.com:dept_eng
   -source-path vs2.example.com:dept_eng_dp_mirror2
   -source-snapshot snap3
   -file-list /file3
Warning: This command will overwrite any file on destination "vs1.example.com:dept_eng" that has the same path as any of the files to be restored.
Do you want to continue? {y|n}: y
[Job 35] Job is queued: snapmirror restore from source "vs2.example.com:dept_eng_dp_mirror2" for the snapshot snap3.
vs1.example.com::>
```

The following example restores /file3 from the source Snapshot copy snap3 on the source volume vs2.example.com:dept_eng_dp_mirror2 to /file3.new in the active file system of the restore destination volume vs1.example.com:dept_eng:

```
vs1.example.com::> snapmirror restore
   -destination-path vs1.example.com:dept_eng
   -source-path vs2.example.com:dept_eng_dp_mirror2
   -source-snapshot snap3
   -file-list /file3,@/file3.new
Warning: This command will overwrite any file on destination "vs1.example.com:dept_eng" that has the same path as any of the files to be restored.
```
Do you want to continue? {y|n}: y
[Job 36] Job is queued: snapmirror restore from source "vs2.example.com:dept_eng_dp_mirror2" for the snapshot snap3.
vs1.example.com:>

The following example restores /file1, /file2, and /file3 from the source Snapshot copy snap3 on the source volume vs2.example.com:dept_eng_dp_mirror2 respectively to /file1.new, /file2, and /file3.new in the active file system of the restore destination volume vs1.example.com:dept_eng:

```
vs1.example.com:/> snapmirror restore
   -destination-path vs1.example.com:dept_eng
   -source-path vs2.example.com:dept_eng_dp_mirror2
   -source-snapshot snap3
   -file-list /file1,@/file1.new,/file2,/file3,@/file3.new
Warning: This command will overwrite any file on destination "vs1.example.com:dept_eng" that has the same path as any of the files to be restored.
Do you want to continue? {y|n}: y
[Job 36] Job is queued: snapmirror restore from source "vs2.example.com:dept_eng_dp_mirror2" for the snapshot snap3.
vs1.example.com:>
```

The following example deletes data from an incomplete file restore, captured in a Snapshot copy which was later promoted to the active file system of a volume.

```
vs1.example.com:/> snapmirror restore
   -destination-path vs1.example.com:dept_eng
   -file-restore-clean-up
Operation is queued: snapmirror restore with "-file-restore-clean-up"
on volume "vs1.example.com:dept_eng".
vs1.example.com:>
```

### snapmirror resume

Enable future transfers

**Availability:** This command is available to `cluster` and `Vserver` administrators at the `admin` privilege level.

**Description**

The `snapmirror resume` command enables future transfers for a SnapMirror relationship that has been quiesced.

- If there is a scheduled transfer for the relationship, it will be triggered on the next schedule. If there is a restart checkpoint, it will be re-used if possible.
- If applied on a load-sharing (LS) SnapMirror relationship, it enables future transfers for all the relationships in the load-sharing set.
When a quiesced SnapMirror relationship is resumed, future transfers remain enabled across reboots and fail-overs.

This command is supported for SnapMirror relationships with the field "Relationship Capability" showing as either "8.2 and above" or "Pre 8.2" in the output of the snapmirror show command.

The snapmirror resume command must be used from the destination Vserver or cluster.

The relationship must exist on the destination Vserver or cluster. When issuing snapmirror resume, you must specify the destination endpoint. The specification of the source endpoint of the relationship is optional.

**Parameters**

`{ [-source-path] -S (<[vserver:][volume]>|[[[cluster://vserver/]volume]>|[hostname://lun/lun-name>]) - Source Path`

Specifies the source endpoint of the SnapMirror relationship in one of two path formats. The normal format includes the names of the Vserver (vserver) and/or volume (volume). To support relationships with "Relationship Capability" of "Pre 8.2", a format which also includes the name of the cluster (cluster) is provided. The "Pre 8.2" format cannot be used when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above".

`| [-source-cluster <Cluster name>] - Source Cluster`

Specifies the source cluster of the SnapMirror relationship. If this parameter is specified, the -source-vserver and -source-volume parameters must also be specified. This parameter is only applicable for relationships with "Relationship Capability" of "Pre 8.2". This parameter cannot be specified when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above".

`[-source-vserver <vserver name>] - Source Vserver`

Specifies the source Vserver of the SnapMirror relationship. For relationships with volumes as endpoints, if this parameter is specified, parameters -source-volume and for relationships with "Relationship Capability" of "Pre 8.2", -source-cluster must also be specified.

`[-source-volume <volume name>] - Source Volume`

Specifies the source volume of the SnapMirror relationship. If this parameter is specified, parameters -source-vserver and for relationships with "Relationship Capability" of "Pre 8.2", -source-cluster must also be specified.

`{ -destination-path (<[vserver:][volume]>|[[[cluster://vserver/]volume]>|[hostname://lun/lun-name>]) - Destination Path`

Specifies the destination endpoint of the SnapMirror relationship in one of two path formats. The normal format includes the names of the Vserver (vserver) and/or volume (volume). To support relationships with "Relationship Capability" of "Pre 8.2", a format which also includes the name of the cluster (cluster) is provided. The "Pre 8.2" format cannot be used when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above".

`| [-destination-cluster <Cluster name>] - Destination Cluster`

Specifies the destination cluster of the SnapMirror relationship. If this parameter is specified, parameters -destination-vserver and -destination-volume must also be specified. This parameter is only applicable for relationships with "Relationship Capability" of "Pre 8.2". This parameter cannot be specified when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above".

`-destination-vserver <vserver name> - Destination Vserver`

Specifies the destination Vserver of the SnapMirror relationship. For relationships with volumes as endpoints, if this parameter is specified, parameters -destination-volume and for relationships with "Relationship Capability" of "Pre 8.2", -destination-cluster must also be specified.
-destination-volume <volume name>} - Destination Volume

Specifies the destination volume of the SnapMirror relationship. If this parameter is specified, parameters -
destination-vserver and for relationships with "Relationship Capability" of "Pre 8.2", -
destination-cluster must also be specified.

Examples

To re-enable future transfers for the SnapMirror relationship with the destination endpoint
vs2.example.com:dept_eng_dp_mirror2 that has been previously quiesced, type the following command:

```
vs2.example.com::> snapmirror resume -destination-path
              vs2.example.com:dept_eng_dp_mirror2
```

To re-enable future transfers for the SnapMirror relationship with the destination endpoint cluster2://
vs2.example.com/dept_eng_dp_mirror2 that has been previously quiesced, type the following command:

```
class2::> snapmirror resume -destination-path
           cluster2://vs2.example.com/dept_eng_dp_mirror2
```

To re-enable future transfers for the Vserver SnapMirror relationship with the destination endpoint dvs1.example.com:
that has been previously quiesced, type the following command:

```
class2::> snapmirror resume -destination-path
           dvs1.example.com:
```

Under PVR control to re-enable future transfers and initiate an Auto Resync of the synchronous SnapMirror Consistency
Group relationship with the destination Consistency Group cg_dst in Vserver vs2.example.com, type the following
command:

```
vs2.example.com::> snapmirror resume -destination-path
                   vs2.example.com:/cg/cg_dst
```

snapmirror resync

Start a resynchronize operation

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description

The snapmirror resync command establishes or reestablishes a mirroring relationship between a source and a destination
endpoint. The endpoints can be Vservers or volumes. snapmirror resync for a SnapMirror relationship with volumes as
endpoints is typically executed in the following cases:

- The destination mirror is broken (that is, the destination volume is a read-write volume and no longer a data protection
  mirror). After the snapmirror resync command completes, the destination volume is made a data protection mirror and
  the mirror can be manually updated or scheduled for updates.
- snapmirror update command failed because the required common Snapshot copy was deleted on the source volume.
• The volumes are the first and third endpoints in a cascade chain of relationships and they have a common Snapshot copy. In this case, snapmirror resync may implicitly create the SnapMirror relationship between them.

Attention: The snapmirror resync command can cause data loss on the destination volume because the command can remove the exported Snapshot copy on the destination volume.

The default behavior of the snapmirror resync command for volume relationships is defined as follows:

• Finds the most recent common Snapshot copy between the source and destination volumes, removes Snapshot copies on the destination volume that are newer than the common Snapshot copy and mounts the destination volume as a DP volume with the common Snapshot copy as the exported Snapshot copy.

• For data protection (DP) relationships, takes a Snapshot copy of the source volume to capture the current image and transfers Snapshot copies that are newer than the common Snapshot copy from the source volume to the destination volume. For extended data protection (XDP) relationships, transfers Snapshot copies newer than the common Snapshot copy according to the relationship policy, i.e., Snapshot copies will match rules associated with the policy as defined by the snapmirror policy commands. For relationships associated with snapmirror policy of type async-mirror and mirror-vault the snapmirror resync first takes a Snapshot copy of the source volume and includes it in the Snapshot copies selected for transfer.

For Vserver SnapMirror relationships, a resync operation is typically executed when the relationship is broken-off, the subtype of the destination Vserver is default and the destination volumes are of type read-write. Once the command is queued, the subtype of the destination Vserver changes from default to dp-destination. A successful resync operation also makes the destination Vserver's volumes data protection volumes.

If the resync command is executed on a Vserver SnapMirror relationship, and the corresponding source and destination Vservers have volumes with volume level SnapMirror relationships, then the volume level SnapMirror relationships will be converted to volumes under the Vserver SnapMirror relationship. This conversion is supported only for source and destination Vservers which have been transitioned from a 7-Mode vFiler into a C-Mode Vserver. Some basic pre-requisites for the conversion are that the destination Vserver should be in a stopped state and all the destination Vserver volumes except the root volume should be in a volume level SnapMirror relationship with volumes of the source Vserver. The state of these volume level SnapMirror relationships should be Snapmirrored and status should be Idle.

The snapmirror resync command supports an optional parameter "preserve". The parameter "preserve" is only supported for extended data protection (XDP) relationships. When used, the parameter "preserve" changes the behavior of snapmirror resync command. Changed behavior of the command can be described as follows:

• Finds the most recent common Snapshot copy between the source and destination volumes, preserves all Snapshot copies on the destination volume that are newer than the common Snapshot copy, and mounts the destination volume as a DP volume with the common Snapshot copy as the exported Snapshot copy.

• Performs a local rollback transfer to make a copy of the common Snapshot copy on the destination volume and establish it as the latest Snapshot copy on the destination volume. The command then transfers all Snapshot copies that are newer than the common Snapshot copy, from the source volume to the destination volume. The command only transfers Snapshot copies that match the relationship's policy, i.e., Snapshot copies will match rules associated with the policy as defined by the snapmirror policy commands.

If a SnapMirror relationship does not already exist, that is, the relationship was not created using the snapmirror create command, the snapmirror resync command will implicitly create the SnapMirror relationship, with the same behaviors as described for the snapmirror create command before resyncing it.

For Infinite Volumes and Vservers, you must create SnapMirror relationships between Infinite Volumes or Vservers by using the snapmirror create command before you run the snapmirror resync command. The snapmirror resync command does not implicitly create the relationship.

This command is supported for SnapMirror relationships with the field "Relationship Capability" showing as either "8.2 and above" or "Pre 8.2" in the output of the snapmirror show command.

For relationships with "Relationship Capability" of "8.2 and above", you can track the progress of the operation using the snapmirror show command.
For relationships with "Relationship Capability" of "Pre 8.2", a job will be spawned to operate on the SnapMirror relationship, and the job id will be shown in the command output. The progress of the job can be tracked using the `job show` and `job history show` commands.

The `snapmirror resync` command fails if the destination volume does not have a Snapshot copy in common with the source volume.

The `snapmirror resync` command does not work on load-sharing mirrors.

The `snapmirror resync` command must be used from the destination Vserver or cluster.

**Parameters**

\{ [-source-path] | -S {<[vserver:]volunue>|<[cluster://vserver/volume>|<[hostname://lun/lun-name>]} - Source Path

Specifies the source endpoint of the SnapMirror relationship in one of two path formats. The normal format includes the names of the Vserver (vserver) and/or volume (volume). To support relationships with "Relationship Capability" of "Pre 8.2", a format which also includes the name of the cluster (cluster) is provided. The "Pre 8.2" format cannot be used when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above".

\{ [-source-cluster <cluster name>] | -Source Cluster

Specifies the source cluster of the SnapMirror relationship. If this parameter is specified, the `-source-vserver` and `-source-volume` parameters must also be specified. This parameter is only applicable for relationships with "Relationship Capability" of "Pre 8.2". This parameter cannot be specified when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above".

\{ [-source-vserver <vserver name>] | -Source Vserver

Specifies the source Vserver of the SnapMirror relationship. For relationships with volumes as endpoints, if this parameter is specified, parameters `-source-volume` and for relationships with "Relationship Capability" of "Pre 8.2", `-source-cluster` must also be specified.

\{ [-source-volume <volume name>] | -Source Volume

Specifies the source volume of the SnapMirror relationship. If this parameter is specified, parameters `-source-vserver` and for relationships with "Relationship Capability" of "Pre 8.2", `-source-cluster` must also be specified.

\{ [-destination-path} {<[vserver:]volumen>|<[cluster://vserver/volume>|<[hostname://lun/lun-name>]} - Destination Path

Specifies the destination endpoint of the SnapMirror relationship in one of two path formats. The normal format includes the names of the Vserver (vserver) and/or volume (volume). To support relationships with "Relationship Capability" of "Pre 8.2", a format which also includes the name of the cluster (cluster) is provided. The "Pre 8.2" format cannot be used when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above".

\{ [-destination-cluster <Cluster name>] | -Destination Cluster

Specifies the destination cluster of the SnapMirror relationship. If this parameter is specified, parameters `-destination-vserver` and `-destination-volume` must also be specified. This parameter is only applicable for relationships with "Relationship Capability" of "Pre 8.2". This parameter cannot be specified when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above".

\{ [-destination-vserver <vserver name>] | -Destination Vserver

Specifies the destination Vserver of the SnapMirror relationship. For relationships with volumes as endpoints, if this parameter is specified, parameters `-destination-volume` and for relationships with "Relationship Capability" of "Pre 8.2", `-destination-cluster` must also be specified.
-destination-volume <volume name> - Destination Volume

Specifies the destination volume of the SnapMirror relationship. If this parameter is specified, parameters -
destination-vserver and for relationships with "Relationship Capability" of "Pre 8.2", -
destination-cluster must also be specified.

[-source-snapshot | -s <text>] - Source Snapshot

This optional parameter specifies a Snapshot copy to transfer. The default behavior for a data protection
relationship with a read-write source is that Data ONTAP creates a new Snapshot copy and uses it as the basis
for determining what data are replicated; with this option, the specified Snapshot copy will be used instead.
The default behavior for an extended data protection relationship depends on the relationship's policy type. For
a data protection relationship, the specified Snapshot copy must be newer than the latest common Snapshot
copy. For an extended data protection relationship, the specified Snapshot copy may be newer or older than the
common Snapshot copy. This parameter is not supported for relationships with "Relationship
Capability" of "Pre 8.2".

[-type <snapmirrorType>] - Snapmirror Relationship Type

Specifies the type of SnapMirror relationship if a relationship is implicitly created. The default is data
protection (DP).

[-policy <sm_policy>] - SnapMirror Policy

This optional parameter designates the name of the SnapMirror policy which is associated with the
SnapMirror relationship. If you do not designate a policy, the current policy will be retained. This parameter is
not applicable to relationships with "Relationship Capability" of "Pre 8.2". This parameter is not
supported by this operation for Infinite Volumes.

Note: You define and name a policy using the snapmirror policy create command.

[-force | -f [true]] - Force

If this parameter is specified, the command proceeds without prompting for confirmation.

[-throttle | -k <throttleType>] - Throttle (KB/sec)

This optional parameter limits the network bandwidth used for the resync transfer. It sets the maximum rate (in
Kbytes/sec) at which data can be transferred during the operation. If this parameter is not specified, the throttle
value configured for the relationship with the snapmirror create or snapmirror modify commands will be used. To specify fully using the network bandwidth available, set the throttle value to unlimited or 0. The
minimum throttle value is four Kbytes/sec, so if you specify a throttle value between 1 and 4, it will be treated
as if you specified 4. The -throttle parameter does not affect load-sharing transfers and transfers for other
relationships with "Relationship Capability" of "Pre 8.2" confined to a single cluster.

[-transfer-priority {low|normal}] - Transfer Priority

This optional parameter specifies the priority at which the transfer runs. The default value for this parameter is
the value in the SnapMirror policy associated with this relationship. This parameter is not applicable to
relationships with a "Relationship Capability" of "Pre 8.2".

[-preserve [true]] - Preserve

This parameter is only supported for extended data protection (XDP) relationships. It is not supported for data
protection and load-sharing relationships. When specified, it changes the behavior of snapmirror resync to
preserve Snapshot copies on the destination volume that are newer than the latest common Snapshot copy.
This parameter is not supported for relationships with "Relationship Capability" of "Pre 8.2". This
option is not supported for Infinite Volume SnapMirror relationships.

[-quick-resync [true]] - Quick Resync

This parameter is only supported for extended data protection (XDP) relationships. Specifying this optional
parameter reduces the resync time because the resync does not incur storage efficiency overhead before the
transfer of new data. Specifying this parameter is recommended if the source of the resync does not have
volume efficiency enabled or if reducing resync time is more important than preserving all possible storage
efficiency. When this parameter is specified, resync does not preserve the storage efficiency of the new data with existing data over the wire and on the destination.

-foreground | -w [true] - Foreground Process
This specifies whether the operation runs as a foreground process. If this parameter is specified, the default setting is true (the operation runs in the foreground). When set to true, the command will not return until the process completes. This parameter is only applicable to relationships with "Relationship Capability" of "Pre 8.2".

Examples
To reestablish mirroring for the destination endpoint vs2.example.com:dept_mkt_mirror that has been previously broken off with the snapmirror break command, type the following command:

```
vs2.example.com::> snapmirror resync -destination-path vs2.example.com:dept_mkt_dp_mirror
```

For relationships with "Relationship Capability" of "Pre 8.2", to reestablish mirroring for the destination endpoint cluster2://vs2.example.com/ dept_mkt_mirror that has been previously broken off with the snapmirror break command, type the following command:

```
cluster2::> snapmirror resync -destination-path
    cluster2://vs2.example.com/dept_mkt_dp_mirror
```

To create a SnapMirror relationship and reestablish mirroring between the destination endpoint named vs2.example.com:dept_eng_dp_mirror2 and the source endpoint named vs1.example.com:dept_eng, type the following command:

```
vs2.example.com::> snapmirror resync -destination-path vs2.example.com:dept_eng_dp_mirror2
    -source-path vs1.example.com:dept_eng
```

To create a SnapMirror relationship and reestablish mirroring between the destination endpoint named cluster2:// vs2.example.com/ dept_eng_dp_mirror2 and the source endpoint named cluster1:// vs1.example.com/ dept_eng when the source cluster is running Data ONTAP 8.1 software, type the following command:

```
cluster2::> snapmirror resync -destination-path
    cluster2://vs2.example.com/dept_eng_dp_mirror2
    -source-path cluster1://vs1.example.com/dept_eng
```

To reestablish mirroring for the destination endpoint dvs1.example.com: of a Vserver relationship that has been previously broken off with the snapmirror break command, type the following command:

```
cluster2::> snapmirror resync -destination-path
dvs1.example.com:
```

Under PVR control to create a SnapMirror synchronous Consistency Group relationship with the following attributes:

- It is between the source Consistency Group cg_src in Vserver vs1.example.com, and the destination Consistency Group cg_dst in Vserver vs2.example.com.
- It has item mappings between lun1 and lun2 on volume srcvol and lun1 and lun2 on volume dstvol.
- It uses a policy named Sync that has a policy type of sync-mirror that the user has previously created.

and reestablish mirroring, type the following command:
Under PVR control to reestablish mirroring to the destination Consistency Group `cg_dst` in Vserver `vs2.example.com` that has been previously broken off with the `snapmirror break` command, type the following command:

```bash
vs2.example.com::> snapmirror resync -destination-path
    vs2.example.com:/cg/cg_dst
```

**snapmirror set-options**

Display/Set SnapMirror options

**Availability:** This command is available to `cluster` administrators at the `admin` privilege level.

**Description**

The `snapmirror set-options` command can be used to display or set snapmirror options. This command is not supported for Infinite Volume SnapMirror relationships.

**Parameters**

- `-dp-source-xfer-reserve-pct (0|25%|50%|75%|100%)` - Percentage Reserved for DP Source Transfers
  
  Specifies the percentage of maximum allowed concurrent transfers reserved for source DP transfers

- `-xdp-source-xfer-reserve-pct (0|25%|50%|75%|100%)` - Percentage Reserved for XDP Source Transfers
  
  Specifies the percentage of maximum allowed concurrent transfers reserved for source XDP transfers

- `-dp-destination-xfer-reserve-pct (0|25%|50%|75%|100%)` - Percentage Reserved for DP Destination Transfers
  
  Specifies the percentage of maximum allowed concurrent transfers reserved for destination DP transfers

- `-xdp-destination-xfer-reserve-pct (0|25%|50%|75%|100%)` - Percentage Reserved for XDP Destination Transfers
  
  Specifies the percentage of maximum allowed concurrent transfers reserved for destination XDP transfers
Examples
The following example displays SnapMirror options:

```bash
cluster1::> snapmirror set-options
Percentage Reserved for DP Source Transfers: 0
Percentage Reserved for XDP Source Transfers: 0
Percentage Reserved for DP Destination Transfers: 0
Percentage Reserved for XDP Destination Transfers: 0
cluster1::> snapmirror set-options -dp-source-xfer-reserve-pct 25
   -xdp-source-xfer-reserve-pct 50  -dp-destination-xfer-reserve-pct 0
   -xdp-destination-xfer-reserve-pct 50
cluster1::> snapmirror set-options
Percentage Reserved for DP Source Transfers: 25
Percentage Reserved for XDP Source Transfers: 50
Percentage Reserved for DP Destination Transfers: 0
Percentage Reserved for XDP Destination Transfers: 50
```

**snapmirror show**

Display a list of SnapMirror relationships

**Availability:** This command is available to cluster and Vserver administrators at the admin privilege level.

**Description**
The `snapmirror show` command displays information associated with SnapMirror relationships. By default, the command displays the following information:

- Source path
- Relationship Type
- Destination Path
- Mirror State
- Relationship Status
- Total Progress
- Healthy
- Progress Last Updated

For backward compatibility with clustered Data ONTAP 8.1, and to accommodate load-sharing relationships which are only supported in a Data ONTAP 8.1 compatible way, SnapMirror relationships, which match one of the following conditions are managed as on clustered Data ONTAP 8.1: (1) The relationship is of type load-sharing; (2) The source endpoint of the relationship is on a remote Data ONTAP 8.1 cluster; (3) The local cluster was upgraded from clustered Data ONTAP 8.1, the relationship was created before the upgrade, and the relationship has not yet been converted to one with Data ONTAP 8.2 capabilities. These relationships have the same limitations as on clustered Data ONTAP 8.1. Especially, they support the same set of information fields. The "Relationship Capability" field is set to "Pre 8.2" for these relationships.

The `snapmirror show` command displays information for SnapMirror relationships whose destination endpoints are in the current Vserver if you are in a Vserver context, or in the current cluster if you are in a cluster context. For backward compatibility with clustered Data ONTAP 8.1, the command also displays information for SnapMirror relationships with the "Relationship Capability" of "Pre 8.2", and whose source endpoints are in the current Vserver or cluster, and destination endpoints are in different Vservers or clusters. You must use the `snapmirror list-destinations` command to display information for SnapMirror relationships whose source endpoints are in the current Vserver or current cluster.
Some of the SnapMirror relationship information is cached. The `snapmirror show` command only returns the cached information, therefore there is a delay after the information is changed before it is reflected in the `snapmirror show` output. Other information, such as progress metrics during a transfer, is only updated periodically and can be very delayed in the `snapmirror show` output.

The `-instance` and `-fields` parameters are mutually exclusive and select the information fields that are displayed. The other parameters to the `snapmirror show` command select the SnapMirror relationships for which information is displayed. The `-instance` displays detailed information fields including:

| Source Path: Path of the source endpoint. |
| Destination Path: Path of the destination endpoint. |
| Relationship Type: Type of the SnapMirror relationship. May be one of the following: |
| - DP: Data protection relationship. |
| - LS: Load-sharing relationship. |
| - XDP: Extended data protection relationship. |
| - RST: Temporary relationship created during a restore operation, and deleted if the operation completes successfully. |
| - TDP: 7-mode to clustered Data ONTAP transition data protection relationship. |
| Relationship Group Type: For FlexVol relationships, specifies the type of the group relationship that includes this FlexVol. For group relationships, specifies the type of the group relationship. Can be one of the following: |
| - none: No group relationship. |
| - vserver: Vserver relationship. |
| - infinitevol: Infinite Volume relationship. |

Only for relationships with "Relationship Capability" of "8.2 and above".

| Relationship Status: Status of the SnapMirror relationship. |
| May be one of the following: |
| - Idle: No transfer operation is in progress and future transfers are not disabled. |
| - Queued: A transfer operation has been accepted and queued in the system, and future transfers are not disabled. |
| - Transferring: A transfer operation is in progress and future transfers are not disabled. |
| - Preparing: Pre-transfer phase for Vault incremental transfers. For Vault relationships only. |
| - Finalizing: Post-transfer phase for Vault incremental transfers. Network traffic will be low as processing is primarily on the destination volume. For Vault relationships only. |
| - Aborting: A transfer abort operation that may include the removal of the checkpoint is underway. Future transfers are not disabled. Only for relationships with "Relationship Capability" of "8.2 and above". |
| - Quiesced: No transfer operation is in... |
progress and future transfers are disabled.
- Quiescing: A transfer operation is in progress and future transfers are disabled.
- Checking: Destination volume is undergoing a diagnostic check, no transfer is in progress, and future transfers are not disabled. Only for relationships with "Relationship Capability" of "Pre 8.2".
- Breaking: The SnapMirror relationship is being broken off and no transfer is in progress.

Mirror State: State of the destination volume. May be one of the following:
- Uninitialized: Destination volume has not been initialized.
- Snapmirrored: Destination volume has been initialized and is ready to receive SnapMirror updates.
- Broken-off: Destination volume is RW and snapshots are present.

Healthy: Condition of the relationship. May be one of the following:
- true: The SnapMirror relationship is healthy. It has not missed a scheduled transfer, or experienced a manual update failure.
- false: The SnapMirror relationship is not healthy. It has missed a scheduled transfer, or has experienced a manual update failure.

Unhealthy Reason: Reason the SnapMirror relationship is not healthy. Only for relationships with "Relationship Capability" of "8.2 and above"

Newest Snapshot: Name of the newest Snapshot copy on the destination volume.
Newest Snapshot Timestamp: Timestamp of the newest Snapshot copy.
Exported Snapshot: Name of the exported Snapshot copy on the destination volume.
Exported Snapshot Timestamp: Timestamp of the exported Snapshot copy.
Lag Time: Time since the exported Snapshot copy was created. It is displayed in the format: hours:minutes:seconds. Only for relationships with "Relationship Capability" of "8.2 and above".

Transfer Type: Type of the current transfer operation. May be one of the following:
- initialize
- update
- resync
- restore
Only for relationships with "Relationship Capability" of "8.2 and above".

Transfer Snapshot: Name of the Snapshot copy being transferred.
Snapshot Progress: Amount of data transferred for the transfer snapshot.
Total Progress: Total amount of data transferred for the current transfer operation.
Network Compression Ratio: The compression ratio achieved for the data sent over the wire as a part of the current transfer operation. The ratio is not
maintained across checkpoint restarts. If network compression is disabled for the transfer, the ratio will be set to 1:1. Only for relationships with "Relationship Capability" of "8.2 and above". This parameter is not supported for Vserver SnapMirror relationships.

Snapshot Checkpoint: The amount of data transferred as recorded in the restart checkpoint of the current or most recent transfer snapshot. If a restart checkpoint is present the next transfer will continue from the checkpoint.

Transfer Error: Possible transient error condition if any, encountered by the current transfer operation. Only for relationships with "Relationship Capability" of "8.2 and above".

Current Throttle: The maximum transfer rate in Kilobytes per second, used for the current transfer between clusters. Only for relationships with "Relationship Capability" of "8.2 and above".

Current Transfer Priority: Priority assigned to the current transfer. Possible values are:
- low
- normal
Only for relationships with "Relationship Capability" of "8.2 and above".

Last Transfer Type: Type of the previous transfer operation:
- initialize
- update
- resync
- restore
Only for relationships with "Relationship Capability" of "8.2 and above".

Last Transfer Size: Total amount of data transferred during the previous transfer operation if it was successful. Only for relationships with "Relationship Capability" of "8.2 and above".

Last Transfer Network Compression Ratio: The compression ratio achieved for the data sent over the wire as a part of the previous transfer operation. If network compression was disabled for the transfer, the ratio will be set to 1:1. Only for relationships with "Relationship Capability" of "8.2 and above". This parameter is not supported for Vserver SnapMirror relationships.

Last Transfer Duration: Duration of the previous transfer operation if it was successful. Only for relationships with "Relationship Capability" of "8.2 and above".

Last Transfer From: Source endpoint of the previous transfer operation. Only for relationships with "Relationship Capability" of "8.2 and above".

Last Transfer End Timestamp: Timestamp of the end of the previous transfer operation. Only for relationships with "Relationship Capability"
Last Transfer Error: Cause of the failure of the previous transfer operation. Only for relationships with "Relationship Capability" of "8.2 and above".

Relationship Capability: Management and control compatibility:
- "Pre 8.2": Management and control of the relationship is compatible with clustered Data ONTAP 8.1.
- "8.2 and above": Full support of clustered Data ONTAP 8.2 or later SnapMirror relationship management and control. This parameter is not supported for Vserver SnapMirror relationships.

Relationship ID: The unique identifier of the relationship. Only for relationships with "Relationship Capability" of "8.2 and above". This parameter is not supported for Vserver SnapMirror relationships.

Current Operation ID: Operation unique identifier of the currently executing SnapMirror operation. Only for relationships with "Relationship Capability" of "8.2 and above".

Throttle (KB/sec): Configured maximum transfer rate for cross-cluster transfers.

SnapMirror Policy Type: Type of the SnapMirror policy associated with the relationship. May be one of the following:
- async-mirror
- vault
- mirror-vault

Refer to the man page for the `snapmirror policy create` command for a description of what these types mean. Only for relationships with "Relationship Capability" of "8.2 and above".

SnapMirror Policy: Name of the SnapMirror policy associated with the relationship. Only for relationships with "Relationship Capability" of "8.2 and above".

SnapMirror Schedule: Name of the schedule (empty if there is no schedule) associated with the relationship.

Tries Limit: Maximum number of times a transfer will be tried. Only for relationships with "Relationship Capability" of "Pre 8.2". This parameter is not supported for Vserver SnapMirror relationships.

Constituent Relationship: Whether or not the SnapMirror relationship is between Infinite Volume constituent volumes. May be:
- true: The relationship is between constituent volumes.
- false: The relationship is not between constituent volumes.

Destination Volume Node: Node which owns the destination volume of the relationship. Only for relationships with "Relationship Capability" of "8.2 and above".
Identity Preserve Vserver DR: Whether or not the identity of the source Vserver is replicated to the destination Vserver. May be:
- true: Source Vserver's configuration will additionally be replicated to the destination, along with the Vserver's volumes and RBAC configuration.
- false: Only volumes and RBAC configuration of the source Vserver is replicated to the destination.

This parameter is supported only for Vserver SnapMirror relationships.

Volume MSIDs Preserved: Whether or not the MSIDs of the source volumes are retained while creating destination volumes. May be:
- true: MSIDs of source Vserver volumes and destination Vserver volumes match.
- false: MSIDs of source Vserver volumes and destination Vserver volumes do not match.

This parameter is supported only for Vserver SnapMirror relationships.

Number of Successful Updates: The number of successful SnapMirror update operations for the relationship. Only for relationships with "Relationship Capability" of "8.2 and above".

This parameter is not supported for Vserver SnapMirror relationships.

Number of Failed Updates: The number of failed SnapMirror update operations for the relationship. Only for relationships with "Relationship Capability" of "8.2 and above".

This parameter is not supported for Vserver SnapMirror relationships.

Number of Successful Resyncs: The number of successful SnapMirror resync operations for the relationship. Only for relationships with "Relationship Capability" of "8.2 and above".

This parameter is not supported for Vserver SnapMirror relationships.

Number of Failed Resyncs: The number of failed SnapMirror resync operations for the relationship. Only for relationships with "Relationship Capability" of "8.2 and above".

This parameter is not supported for Vserver SnapMirror relationships.

Number of Successful Breaks: The number of successful SnapMirror break operations for the relationship. Only for relationships with "Relationship Capability" of "8.2 and above".

This parameter is not supported for Vserver SnapMirror relationships.

Number of Failed Breaks: The number of failed SnapMirror break operations for the relationship. Only for relationships with "Relationship Capability" of "8.2 and above".

This parameter is not supported for Vserver SnapMirror relationships.

Total Transfer Bytes: Cumulative bytes transferred for the relationship. Only for relationships with "Relationship Capability" of "8.2 and above".
This parameter is not supported for Vserver SnapMirror relationships.

Total Transfer Time: Cumulative total transfer time in seconds for the relationship.
Only for relationships with "Relationship Capability" of "8.2 and above".
This parameter is not supported for Vserver SnapMirror relationships.

Parameters

{{-fields <fieldname>, ...}}

If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use -fields ? to display the fields to specify.

{{-instance}}

If you specify the -instance parameter, the command displays detailed information about all fields.

{{-source-path | -S <[vserver:]|volume> | [[cluster://vserver/]volume> | [[hostname:/lun/lun-name>]] - Source Path

Select SnapMirror relationships that have a matching source path name.

{{-source-cluster <Cluster name>}} - Source Cluster

Select SnapMirror relationships that have a matching source cluster name.

{{-source-vserver <vserver name>}} - Source Vserver

Select SnapMirror relationships that have a matching source Vserver name.

{{-source-volume <volume name>]] - Source Volume

Select SnapMirror relationships that have a matching source volume name.

{{-destination-path <[vserver:]|volume> | [[cluster://vserver/]volume> | [[hostname:/lun/lun-name>]] - Destination Path

Select SnapMirror relationships that have a matching destination path name.

Note: Using wildcards with this parameter:

• To match all Vserver Snapmirror relationships, use: -destination-path *:

• To match all the Snapmirror relationships except Vserver Snapmirror relationships in the cluster, use: -destination-path *

{{-destination-cluster <Cluster name>]] - Destination Cluster

Select SnapMirror relationships that have a matching destination cluster name.

{{-destination-vserver <vserver name>]] - Destination Vserver

Select SnapMirror relationships that have a matching destination Vserver name.

{{-destination-volume <volume name>]] - Destination Volume

Select SnapMirror relationships that have a matching destination volume name.

{{-type <snapmirrorType>]] - Relationship Type

Select SnapMirror relationships that have a matching relationship type. Infinite Volumes and Vservers support only DP SnapMirror relationships. Possible values are:

• DP
• LS
• XDP

Commands: Manual Page Reference

544
- TDP
- RST

[-relationship-group-type {none|vserver|infinitevol|consistencygroup}] - Relationship Group Type
Select SnapMirror relationships that have a matching relationship group type. Possible values are:
- none
- vserver
- infinitevol

[-vserver <vserver name>] - Managing Vserver
Select SnapMirror relationships that have a matching managing Vserver name. The -vserver option is currently a reserved option.

[-schedule <text>] - SnapMirror Schedule
Select SnapMirror relationships that have a matching schedule.

[-policy-type {vault|async-mirror|mirror-vault}] - SnapMirror Policy Type
Selects SnapMirror relationships that have a matching SnapMirror policy type. Possible values are:
- async-mirror
- vault
- mirror-vault

[-policy <sm_policy>] - SnapMirror Policy
Select SnapMirror relationships that have a matching SnapMirror policy.

[-tries <unsigned32_or_unlimited>] - Tries Limit
Select SnapMirror relationships that have a matching tries limit.

[-throttle | -k <throttleType>] - Throttle (KB/sec)
Select SnapMirror relationships that have a matching throttle.

[-current-throttle <throttleType>] - Current Transfer Throttle (KB/sec)
Select SnapMirror relationships that have a matching current throttle.

[-state <mirror state>] - Mirror State
Select SnapMirror relationships that have a matching mirror state. Possible values are:
- Uninitialized
- Snapmirrored
- Broken-off

[-status <mirror status>] - Relationship Status
Select SnapMirror relationships that have a matching relationship status. Possible values are:
- Idle
- Queued
- Transferring
- Preparing
- Finalizing
• Aborting
• Quiesced
• Quiescing
• Checking

Status values Finalizing, Checking and Waiting are not supported for Infinite Volume SnapMirror relationships. Status values Finalizing, Checking, Waiting and Preparing are not supported for Vserver SnapMirror relationships.

[-file-restore-file-count <integer>] - File Restore File Count
The number of files being restored by file restore.

[-file-restore-file-list <text>, ...] - File Restore File List
List of the destination file names of the files being restored by file restore.

[-transfer-snapshot <text>] - Transfer Snapshot
Select SnapMirror relationships that have a matching transfer Snapshot copy.

[-snapshot-progress {<integer> [KB|MB|GB|TB|PB]}] - Snapshot Progress
Select SnapMirror relationships that have a matching Snapshot progress.

[-total-progress {<integer> [KB|MB|GB|TB|PB]}] - Total Progress
Select SnapMirror relationships that have a matching total progress.

[-network-compression-ratio <text>] - Network Compression Ratio
Select SnapMirror relationships that have a matching network compression ratio. This parameter is not supported for Vserver SnapMirror relationships.

[-snapshot-checkpoint {<integer> [KB|MB|GB|TB|PB]}] - Snapshot Checkpoint
Select SnapMirror relationships that have a matching Snapshot copy checkpoint. This parameter is not supported for Vserver SnapMirror relationships.

[-newest-snapshot <text>] - Newest Snapshot
Select SnapMirror relationships that have a matching newest Snapshot copy.

Select SnapMirror relationships that have a matching newest Snapshot copy timestamp.

[-exported-snapshot <text>] - Exported Snapshot
Select SnapMirror relationships that have a matching exported Snapshot copy name. For load-sharing mirror relationships, if the exported-snapshot field for a relationship has a dash (-), the load-sharing mirror is lagging behind the up-to-date mirrors in the set.

[-exported-snapshot-timestamp <MM/DD HH:MM:SS>] - Exported Snapshot Timestamp
Select SnapMirror relationships that have a matching exported Snapshot copy timestamp.

[-healthy {true|false}] - Healthy
Select SnapMirror relationships that have a matching healthy condition.

[-relationship-id <UUID>] - Relationship ID
Select SnapMirror relationships that have a matching relationship ID. This parameter is not supported for Vserver SnapMirror relationships.

[-current-operation-id <UUID>] - Current Operation ID
Select SnapMirror relationships that have a matching operation unique identifier of the currently executing SnapMirror operation.
-current-transfer-type {initialize|update|resync|restore|check|file_restore|cggrs_initialize|cggrs_resync|cg_update|cg_initialize} - Transfer Type
  Select SnapMirror relationships that have a matching current transfer type. Transfer type Check is not supported for Infinite Volume SnapMirror relationships.

-current-transfer-error <text> - Transfer Error
  Select SnapMirror relationships that have a matching current transfer error.

-last-transfer-type {initialize|update|resync|restore|check|file_restore|cggrs_initialize|cggrs_resync|cg_update|cg_initialize} - Last Transfer Type
  Select SnapMirror relationships that have a matching last transfer type.

-last-transfer-error <text> - Last Transfer Error
  Select SnapMirror relationships that have a matching last transfer error.

-last-transfer-size {<integer>[KB|MB|GB|TB|PB]} - Last Transfer Size
  Select SnapMirror relationships that have a matching last transfer size.

-last-transfer-network-compression-ratio <text> - Last Transfer Network Compression Ratio
  Select SnapMirror relationships that have a matching last transfer network compression ratio. This parameter is not supported for Vserver SnapMirror relationships.

-last-transfer-duration <([<hours>:]<minutes>:)<seconds>> - Last Transfer Duration
  Select SnapMirror relationships that have a matching last transfer duration.

-last-transfer-from <text> - Last Transfer From
  Select SnapMirror relationships that have a matching last transfer source.

-last-transfer-end-timestamp <MM/DD HH:MM:SS> - Last Transfer End Timestamp
  Select SnapMirror relationships that have a matching last transfer end timestamp.

-unhealthy-reason <text> - Unhealthy Reason
  Select SnapMirror relationships that have a matching unhealthy reason. This option is not supported for Infinite Volume SnapMirror relationships.

-progress-last-updated <MM/DD HH:MM:SS> - Progress Last Updated
  Select SnapMirror relationships that have a matching progress last updated.

-relationship-capability <text> - Relationship Capability
  Select SnapMirror relationships that have a matching relationship capability. This parameter is not supported for Vserver SnapMirror relationships.

-lag-time <([<hours>:]<minutes>:)<seconds>> - Lag Time
  Select SnapMirror relationships that have a matching lag time.

-current-transfer-priority {low|normal} - Current Transfer Priority
  Select SnapMirror relationships that have a matching current transfer priority.

-is-smtape-op {true|false} - SMtape Operation
  Select SnapMirror relationships that have a matching smtape operation. This option is not supported for Infinite Volume SnapMirror relationships.

-is-constituent {true|false} - Constituent Relationship
  Select SnapMirror relationships that have a matching constituent condition.

-destination-volume-node <nodename> - Destination Volume Node Name
  Select SnapMirror relationships that have a matching destination volume node name. This parameter is not supported for Vserver SnapMirror relationships.
[-identity-preserve {true|false}] - Identity Preserve Vserver DR
Select SnapMirror relationships that have a matching value for identity-preserve. This parameter is valid only for Vserver SnapMirror relationships.

[-expand {true}] - Show Constituents of the Group
Specifies whether to display constituent relationships of Vserver SnapMirror relationships. By default, the constituents are not displayed.

[-update-successful-count <integer>] - Number of Successful Updates
Select SnapMirror relationships that have a matching number of successful updates. This parameter is not supported for Vserver SnapMirror relationships.

[-update-failed-count <integer>] - Number of Failed Updates
Select SnapMirror relationships that have a matching number of failed updates. This parameter is not supported for Vserver SnapMirror relationships.

[-resync-successful-count <integer>] - Number of Successful Resyncs
Select SnapMirror relationships that have a matching number of successful resyncs. This parameter is not supported for Vserver SnapMirror relationships.

[-resync-failed-count <integer>] - Number of Failed Resyncs
Select SnapMirror relationships that have a matching number of failed resyncs. This parameter is not supported for Vserver SnapMirror relationships.

[-break-successful-count <integer>] - Number of Successful Breaks
Select SnapMirror relationships that have a matching number of successful breaks. This parameter is not supported for Vserver SnapMirror relationships.

[-break-failed-count <integer>] - Number of Failed Breaks
Select SnapMirror relationships that have a matching number of failed breaks. This parameter is not supported for Vserver SnapMirror relationships.

[-total-transfer-bytes <integer>] - Total Transfer Bytes
Select SnapMirror relationships that have a matching total transfer bytes. This parameter is not supported for Vserver SnapMirror relationships.

[-total-transfer-time-secs <integer>] - Total Transfer Time in Seconds
Select SnapMirror relationships that have a matching total transfer time in seconds. This parameter is not supported for Vserver SnapMirror relationships.

[-msid-preserve {true|false}] - Source Volume MSIDs Preserved
This parameter specifies whether the volume MSIDs are preserved at the destination. This parameter is applicable only for Vserver SnapMirror relationships.

Examples
The `snapmirror show` command displays information associated with SnapMirror relationships. By default, the command displays the following information:

- Source path
- Relationship Type
- Destination Path
- Mirror State
- Relationship Status
- Total Progress
For backward compatibility with clustered Data ONTAP 8.1, and to accommodate load-sharing relationships which are only supported in a Data ONTAP 8.1 compatible way, SnapMirror relationships, which match one of the following conditions are managed as on clustered Data ONTAP 8.1: (1) The relationship is of type load-sharing; (2) The source endpoint of the relationship is on a remote Data ONTAP 8.1 cluster; (3) The local cluster was upgraded from clustered Data ONTAP 8.1, the relationship was created before the upgrade, and the relationship has not yet been converted to one with Data ONTAP 8.2 capabilities. These relationships have the same limitations as on clustered Data ONTAP 8.1. Especially, they support the same set of information fields. The "Relationship Capability" field is set to "Pre 8.2" for these relationships.

The `snapmirror show` command displays information for SnapMirror relationships whose destination endpoints are in the current Vserver if you are in a Vserver context, or in the current cluster if you are in a cluster context. For backward compatibility with clustered Data ONTAP 8.1, the command also displays information for SnapMirror relationships with the "Relationship Capability" of "Pre 8.2", and whose source endpoints are in the current Vserver or cluster, and destination endpoints are in different Vservers or clusters. You must use the `snapmirror list-destinations` command to display information for SnapMirror relationships whose source endpoints are in the current Vserver or current cluster.

Some of the SnapMirror relationship information is cached. The `snapmirror show` command only returns the cached information, therefore there is a delay after the information is changed before it is reflected in the `snapmirror show` output. Other information, such as progress metrics during a transfer, is only updated periodically and can be very delayed in the `snapmirror show` output.

The `-instance` and `-fields` parameters are mutually exclusive and select the information fields that are displayed. The other parameters to the `snapmirror show` command select the SnapMirror relationships for which information is displayed. The `-instance` displays detailed information fields including:

<table>
<thead>
<tr>
<th>Source Path: Path of the source endpoint.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Destination Path: Path of the destination endpoint.</td>
</tr>
<tr>
<td>Relationship Type: Type of the SnapMirror relationship. May be one of the following:</td>
</tr>
<tr>
<td>- DP: Data protection relationship.</td>
</tr>
<tr>
<td>- LS: Load-sharing relationship.</td>
</tr>
<tr>
<td>- XDP: Extended data protection relationship.</td>
</tr>
<tr>
<td>- RST: Temporary relationship created during a restore operation, and deleted if the operation completes successfully.</td>
</tr>
<tr>
<td>- TDP: 7-mode to clustered Data ONTAP transition data protection relationship.</td>
</tr>
<tr>
<td>Relationship Group Type: For FlexVol relationships, specifies the type of the group relationship that includes this FlexVol. For group relationships, specifies the type of the group relationship. Can be one of the following:</td>
</tr>
<tr>
<td>- none: No group relationship.</td>
</tr>
<tr>
<td>- vserver: Vserver relationship.</td>
</tr>
<tr>
<td>- infinitevol: Infinite Volume relationship.</td>
</tr>
</tbody>
</table>

Under PVR control the following group type is available:
- consistencygroup: Consistency Group relationship.

There are no FlexVol relationships with group type of consistencygroup, only Consistency Group relationships and item-level relationships.
Only for relationships with "Relationship Capability" of "8.2 and above".

Relationship Status: Status of the SnapMirror relationship. May be one of the following:
- Idle: No transfer operation is in progress and future transfers are not disabled.
- Queued: A transfer operation has been accepted and queued in the system, and future transfers are not disabled.
- Transferring: A transfer operation is in progress and future transfers are not disabled.
- Preparing: Pre-transfer phase for Vault incremental transfers.
  For Vault relationships only.
- Finalizing: Post-transfer phase for Vault incremental transfers.
  Network traffic will be low as processing is primarily on the destination volume.
  For Vault relationships only.
- Aborting: A transfer abort operation that may include the removal of the checkpoint is underway. Future transfers are not disabled. Only for relationships with "Relationship Capability" of "8.2 and above".
- Quiesced: No transfer operation is in progress and future transfers are disabled.
- Quiescing: A transfer operation is in progress and future transfers are disabled.
- Checking: Destination volume is undergoing a diagnostic check, no transfer is in progress, and future transfers are not disabled. Only for relationships with "Relationship Capability" of "Pre 8.2".
- Breaking: The SnapMirror relationship is being broken off and no transfer is in progress.

The following values are only applicable to relationships with policy type sync-mirror under PVR control:
- OutOfSync: The SnapMirror relationship is not InSync and no async transfer operation is in progress.
- PreCutover: The SnapMirror relationship is setting up for the last transfer prior Cutover to InSync.
- Cutover: The SnapMirror relationship is transitioning to InSync.
- InSync: The SnapMirror relationship is InSync.

Mirror State: State of the destination volume. May be one of the following:
- Uninitialized: Destination volume has not been initialized.
- Snapmirrored: Destination volume has been initialized and is ready to receive SnapMirror updates.
- Broken-off: Destination volume is RW and snapshots are present.

Healthy: Condition of the relationship. May be one of
the following:
- true: The SnapMirror relationship is healthy. It has not missed a scheduled transfer, or experienced a manual update failure.
- false: The SnapMirror relationship is not healthy. It has missed a scheduled transfer, or has experienced a manual update failure.

Unhealthy Reason: Reason the SnapMirror relationship is not healthy. Only for relationships with "Relationship Capability" of "8.2 and above"

Newest Snapshot: Name of the newest Snapshot copy on the destination volume.

Newest Snapshot Timestamp: Timestamp of the newest Snapshot copy.

Exported Snapshot: Name of the exported Snapshot copy on the destination volume.

Exported Snapshot Timestamp: Timestamp of the exported Snapshot copy.

Lag Time: Time since the exported Snapshot copy was created. It is displayed in the format: hours:minutes:seconds. Only for relationships with "Relationship Capability" of "8.2 and above".

Transfer Type: Type of the current transfer operation. May be one of the following:
- initialize
- update
- resync
- restore
Only for relationships with "Relationship Capability" of "8.2 and above".

Transfer Snapshot: Name of the Snapshot copy being transferred.

Snapshot Progress: Amount of data transferred for the transfer snapshot.

Total Progress: Total amount of data transferred for the current transfer operation.

Network Compression Ratio: The compression ratio achieved for the data sent over the wire as a part of the current transfer operation. The ratio is not maintained across checkpoint restarts. If network compression is disabled for the transfer, the ratio will be set to 1:1. Only for relationships with "Relationship Capability" of "8.2 and above". This parameter is not supported for Vserver SnapMirror relationships.

Snapshot Checkpoint: The amount of data transferred as recorded in the restart checkpoint of the current or most recent transfer snapshot. If a restart checkpoint is present the next transfer will continue from the checkpoint.

Transfer Error: Possible transient error condition if any, encountered by the current transfer operation. Only for relationships with "Relationship Capability" of "8.2 and above".

Current Throttle: The maximum transfer rate in Kilobytes per second, used for the current transfer between clusters. Only for relationships with "Relationship Capability" of "8.2 and above".

Current Transfer Priority: Priority assigned to the current transfer. Possible values are:
- low
- normal
Only for relationships with "Relationship Capability" of "8.2 and above".

Last Transfer Type: Type of the previous transfer operation:
- initialize
- update
- resync
- restore
Only for relationships with "Relationship Capability" of "8.2 and above".

Last Transfer Size: Total amount of data transferred during the previous transfer operation if it was successful. Only for relationships with "Relationship Capability" of "8.2 and above".

Last Transfer Network Compression Ratio: The compression ratio achieved for the data sent over the wire as a part of the previous transfer operation. If network compression was disabled for the transfer, the ratio will be set to 1:1. Only for relationships with "Relationship Capability" of "8.2 and above". This parameter is not supported for Vserver SnapMirror relationships.

Last Transfer Duration: Duration of the previous transfer operation if it was successful. Only for relationships with "Relationship Capability" of "8.2 and above".

Last Transfer From: Source endpoint of the previous transfer operation. Only for relationships with "Relationship Capability" of "8.2 and above".

Last Transfer End Timestamp: Timestamp of the end of the previous transfer operation. Only for relationships with "Relationship Capability" of "8.2 and above".

Last Transfer Error: Cause of the failure of the previous transfer operation. Only for relationships with "Relationship Capability" of "8.2 and above".

Relationship Capability: Management and control compatibility:
- "Pre 8.2": Management and control of the relationship is compatible with clustered Data ONTAP 8.1.
- "8.2 and above": Full support of clustered Data ONTAP 8.2 or later SnapMirror relationship management and control. This parameter is not supported for Vserver SnapMirror relationships.

Relationship ID: The unique identifier of the relationship. Only for relationships with "Relationship Capability" of "8.2 and above". This parameter is not supported for Vserver SnapMirror relationships.

Current Operation ID: Operation unique identifier of the currently executing SnapMirror operation. Only for relationships with "Relationship Capability" of "8.2 and above".

Throttle (KB/sec): Configured maximum transfer rate for cross-cluster transfers.

SnapMirror Policy Type: Type of the SnapMirror policy associated with the relationship. May be one of the following:
- async-mirror
- vault
- mirror-vault

Under PVR control the following type is available:
- sync-mirror
Refer to the man page for the `snapmirror policy create` command for a description of what these types mean. Only for relationships with "Relationship Capability" of "8.2 and above".

**SnapMirror Policy:** Name of the SnapMirror policy associated with the relationship. Only for relationships with "Relationship Capability" of "8.2 and above".

**SnapMirror Schedule:** Name of the schedule (empty if there is no schedule) associated with the relationship.

**Tries Limit:** Maximum number of times a transfer will be tried. Only for relationships with "Relationship Capability" of "Pre 8.2". This parameter is not supported for Vserver SnapMirror relationships.

**Constituent Relationship:** Whether or not the SnapMirror relationship is between Infinite Volume constituent volumes. May be:
- true: The relationship is between constituent volumes.
- false: The relationship is not between constituent volumes.

**Destination Volume Node:** Node which owns the destination volume of the relationship. Only for relationships with "Relationship Capability" of "8.2 and above". This parameter is not supported for Vserver SnapMirror relationships.

**Identity Preserve Vserver DR:** Whether or not the identity of the source Vserver is replicated to the destination Vserver. May be:
- true: Source Vserver's configuration will additionally be replicated to the destination, along with the Vserver's volumes and RBAC configuration.
- false: Only volumes and RBAC configuration of the source Vserver is replicated to the destination.

This parameter is supported only for Vserver SnapMirror relationships.

**Volume MSIDs Preserved:** Whether or not the MSIDs of the source volumes are retained while creating destination volumes. May be:
- true: MSIDs of source Vserver volumes and destination Vserver volumes match.
- false: MSIDs of source Vserver volumes and destination Vserver volumes do not match.

This parameter is supported only for Vserver SnapMirror relationships.

**Number of Successful Updates:** The number of successful SnapMirror update operations for the relationship. Only for relationships with "Relationship Capability" of "8.2 and above". This parameter is not supported for Vserver SnapMirror relationships.

**Number of Failed Updates:** The number of failed SnapMirror update operations for the relationship. Only for relationships with "Relationship Capability" of "8.2 and above". This parameter is not supported for Vserver SnapMirror relationships.

**Number of Successful Resyncs:** The number of successful SnapMirror resync operations for the relationship. Only for relationships with "Relationship Capability" of "8.2 and above". This parameter is not supported for Vserver SnapMirror relationships.
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number of Failed Resyncs</td>
<td>The number of failed SnapMirror resync operations for the relationship. Only for relationships with &quot;Relationship Capability&quot; of &quot;8.2 and above&quot;. This parameter is not supported for Vserver SnapMirror relationships.</td>
</tr>
<tr>
<td>Number of Successful Breaks</td>
<td>The number of successful SnapMirror break operations for the relationship. Only for relationships with &quot;Relationship Capability&quot; of &quot;8.2 and above&quot;. This parameter is not supported for Vserver SnapMirror relationships.</td>
</tr>
<tr>
<td>Number of Failed Breaks</td>
<td>The number of failed SnapMirror break operations for the relationship. Only for relationships with &quot;Relationship Capability&quot; of &quot;8.2 and above&quot;. This parameter is not supported for Vserver SnapMirror relationships.</td>
</tr>
<tr>
<td>Total Transfer Bytes</td>
<td>Cumulative bytes transferred for the relationship. Only for relationships with &quot;Relationship Capability&quot; of &quot;8.2 and above&quot;. This parameter is not supported for Vserver SnapMirror relationships.</td>
</tr>

<td>Cumulative total transfer time in seconds for the relationship. Only for relationships with &quot;Relationship Capability&quot; of &quot;8.2 and above&quot;. This parameter is not supported for Vserver SnapMirror relationships.</td>
</tr>
</tbody>
</table>

The following fields are available only under PVR control for relationships with policy type `sync-mirror`:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number of Successful PCS</td>
<td>The number of successful Pseudo Common Snapshot copy creation operations for the relationship. Pseudo Common Snapshot copies are created periodically for use by SnapMirror so that there is always a comparatively recent common Snapshot copy that can be used to get a relationship with policy type <code>sync-mirror</code> back InSync quickly.</td>
</tr>
<tr>
<td>Number of Failed PCS</td>
<td>The number of failed Pseudo Common Snapshot copy creation operations for the relationship.</td>
</tr>
<tr>
<td>Average Time of Resync Operations</td>
<td>Average duration in seconds of resync operations on relationships with policy type <code>sync-mirror</code>.</td>
</tr>
</tbody>
</table>

The following fields are available only at the diagnostic privilege level:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Last Transfer Error Codes</td>
<td>Set of Data ONTAP internal error codes providing information on the context of the previous transfer failure. Only for relationships with &quot;Relationship Capability&quot; of &quot;8.2 and above&quot;. This parameter is not supported for Vserver SnapMirror relationships.</td>
</tr>
<tr>
<td>Source Vserver UUID</td>
<td>The unique identifier of the source Vserver. Only for relationships with &quot;Relationship Capability&quot; of &quot;8.2 and above&quot;.</td>
</tr>
<tr>
<td>Destination Vserver UUID</td>
<td>The unique identifier of the destination.</td>
</tr>
</tbody>
</table>
Vserver.
Only for relationships with
"Relationship Capability"
of "8.2 and above".

The example below displays summary information for all SnapMirror relationships with destination endpoints in the current cluster:

**snapmirror show-history**

Displays history of SnapMirror operations.

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

**Description**

The `snapmirror show-history` command displays history of the SnapMirror operations. By default, the command displays the following information:

- Destination Path
- Source Path
- Operation
- Start Time
- End Time
- Result

The `snapmirror show-history` command displays - in reverse chronological order - the history of completed SnapMirror operations whose destination endpoints are in the current Vserver for Vserver administrators, or the current cluster for cluster administrators. This command does not return information about operations which happened prior to installing Data ONTAP 8.3. Also, it does not return information for relationships with the "Relationship Capability" field, as shown in the output of the `snapmirror show` command, set to "Pre 8.2".

The `-instance` parameter displays the following detailed information:

- **Destination Path:** Path of the destination endpoint.
- **Source Path:** Path of the source endpoint.
- **Relationship ID:** The unique identifier of the relationship. This parameter is not supported for Vserver SnapMirror relationships.
- **Relationship Group Type:** For FlexVol relationships, specifies the type of the group relationship that includes this FlexVol. For group relationships, specifies the type of the group relationship. Can be one of the following:
  - none: No group relationship.
  - vserver: Vserver relationship.
  - infinitevol: Infinite Volume relationship.
- **Operation:** Type of the operation. May be one of the following:
  - create
  - modify
  - quiesce
  - resume
  - delete
  - initialize
  - manual update
  - scheduled update
  - break
  - resync
  - abort
  - restore
- **Operation ID:** The unique identifier of the operation.
- **Start Time:** Timestamp of the start of the operation.
- **End Time:** Timestamp of the end of the operation.
Result: Result of the SnapMirror operation.
      May be one of the following:
      - success
      - failure

Transfer Size: Total amount of data transferred during the
      SnapMirror operation.

Additional Information: A message describing the cause of the
      failure or additional information about a
      successful operation such as if a checkpoint
      was cleared as part of an abort operation.

Parameters

{ [-fields <fieldname>, ...]
   If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified
   field or fields. You can use ‘-fields ?’ to display the fields to specify.

[-instance ]
   If you specify the -instance parameter, the command displays detailed information about all fields.

{ [-destination-path {<vserver:><volume>|<cluster://vserver/volume>|<hostname:/lun/lun-name>}]} - Destination Path
   Select SnapMirror operations that have a matching destination path name.

[-destination-vserver <vserver name>] - Destination Vserver
   Select SnapMirror operations that have a matching destination Vserver name.

[-destination-volume <volume name>]} - Destination Volume
   Select SnapMirror operations that have a matching destination volume name.

[-operation-id <UUID>] - Operation ID
   Select SnapMirror operations that have a matching operation ID.

[-source-path {<vserver:><volume>|<cluster://vserver/volume>|<hostname:/lun/lun-name>}]} - Source Path
   Select SnapMirror operations that have a matching source path name.

[-source-vserver <vserver name>] - Source Vserver
   Select SnapMirror operations that have a matching source Vserver name.

[-source-volume <volume name>]} - Source Volume
   Select SnapMirror operations that have a matching source volume name.

[-operation-type {create|modify|quiesce|resume|delete|initialize|manual-update|scheduled-update|break|resync|abort|restore}] - Operation Type
   Select SnapMirror operations that have a matching operation type. Possible values are:
     • create
     • modify
     • quiesce
     • resume
     • delete
     • initialize
     • manual-update
• scheduled-update
• break
• resync
• abort
• restore

[-start-time <MM/DD/YYYY HH:MM:SS>] - Start Time
Select SnapMirror operations that have a matching start time.

[-end-time <MM/DD/YYYY HH:MM:SS>] - End Time
Select SnapMirror operations that have a matching end time.

[-relationship-id <UUID>] - Relationship ID
Select SnapMirror operations that have a matching relationship ID.

[-relationship-group-type {none|vserver|infinitevol|consistencygroup}] - Relationship Group Type
Select SnapMirror relationships that have a matching relationship group type. Possible values are:

• none
• vserver
• infinitevol

[-result {success|failure}] - Result of the Operation
Select SnapMirror operations that have a matching result. Possible values are:

• success
• failure

[-transfer-size (<integer> [KB|MB|GB|TB|PB])] - Transfer Size
Select SnapMirror operations that have a matching transfer size.

[-additional-info <text>] - Additional Information
Select SnapMirror operations that have a matching additional information.

[-max-rows-per-relationship <integer>] - Maximum Number of Rows per Relationship
Select matching number of SnapMirror operations per relationship.

[-expand [true]] - Show Constituents of the Group.
Select SnapMirror operations on relationships that are constituents and non-constituents of a group.

Examples
The example below displays summary information for all SnapMirror operations on relationships with destination endpoints in the current cluster:

```
cluster2::> snapmirror show-history
Destination    Source    Start     Operation       End      Result
Path         Path         Time       Time            -------

```
The example below displays detailed information for the SnapMirror operation with operation ID

```
dc158715-0583-11e3-89bd-123478563412
```

```
cluster2::> snapmirror show-history -operation-id dc158715-0583-11e3-89bd-123478563412

Destination Path: vs1:vol1
Source Path: vs1:aggr1
Relationship ID: cb3d30a0-0583-11e3-89bd-123478563412
Relationship Group Type: none
Operation: manual-update
Operation ID: dc158715-0583-11e3-89bd-123478563412
Start Time: 8/15/2013 08:22:44
End Time: 8/15/2013 08:22:44
Result: failure
Transfer Size: -
Additional Information: Volume vs1:vol1 is restricted. Use the command "volume online" to bring the volume online.
```

The example below displays detailed information for all SnapMirror operations on relationships with the Result of "success" and whose destination endpoints are in the current cluster.

```
cluster2::> snapmirror show-history -result success

Destination Path: vs1:vol1
Source Path: vs1:aggr1
Relationship ID: cb3d30a0-0583-11e3-89bd-123478563412
Relationship Group Type: none
Operation: create
Operation ID: cb3d305d-0583-11e3-89bd-123478563412
Start Time: 8/15/2013 08:22:15
End Time: 8/15/2013 08:22:16
Result: success
Transfer Size: -
Additional Information: -
```

```
Destination Path: vs1:vol2

### snapmirror update

Start an incremental transfer

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

**Description**

The `snapmirror update` command updates the destination volume of a SnapMirror relationship. The `snapmirror update` command behaves differently for data protection (DP), extended data protection (XDP) and load-sharing (LS) relationships. Refer to parameter "type" from `snapmirror create` to understand different types of relationships supported by SnapMirror.

The `snapmirror update` command performs an incremental transfer.

Before using this command, the relationship must be initialized using the `snapmirror initialize` or `snapmirror initialize-ls-set` commands.

For data protection SnapMirror relationships with volumes as endpoints, the `snapmirror update` command makes the destination volume an up-to-date mirror of the source volume with the following steps:

- If the source volume is read-write, takes a Snapshot copy on the source volume to capture the current image of the source volume
- Finds the most recent Snapshot copy on the destination volume and validates that the corresponding Snapshot copy is still present on the source
- Incrementally transfers Snapshot copies that are newer than the corresponding Snapshot copy to the destination volume

You can use the `snapmirror update` command to update a specific load-sharing mirror that lags behind up-to-date destination volumes in the set of load-sharing mirrors. An update to the lagging load-sharing mirror should bring it up to date with the other up-to-date destination volumes in the set of load-sharing mirrors.

**Note:** Using the `snapmirror update` command to update a set of load-sharing mirrors will not work. Use the `snapmirror update-ls-set` command to update a set of load-sharing mirrors.

For extended data protection (XDP) relationships with a `snapmirror policy` of type async-mirror, a `snapmirror update` always creates a new Snapshot copy on the source volume. Depending on the rules in the policy, the command may...
transfer just the newly created Snapshot copy or all Snapshot copies that are newer than the common Snapshot copy including
the newly created Snapshot copy to the destination volume.

For extended data protection (XDP) relationships with a snapmirror policy of type vault, a snapmirror update does
not create a new Snapshot copy on the source volume but transfers only selected Snapshot copies that are newer than
the common Snapshot copy to the destination volume. (Those older than the common copy can be transferred by using the –
source-snapshot parameter.) Snapshot copies are selected by matching the value of –snapmirror-label of a Snapshot
copy with the value of –snapmirror-label of one of the rules from the corresponding SnapMirror policy associated with the
SnapMirror relationship. All matching Snapshot copies are incrementally transferred to the destination volume.

For extended data protection (XDP) relationships with a snapmirror policy of type mirror-vault, a snapmirror
update always creates a new Snapshot copy on the source volume and transfers only selected Snapshot copies that are newer
than the common snapshot copy. The newly created Snapshot copy is always selected.

For extended data protection (XDP) relationships with a snapmirror policy of type vault or mirror-vault, the
snapmirror update command also manages expiration of Snapshot copies on the destination volume. It does so by deleting
Snapshot copies that have exceeded the value of –keep for the matching rule from the corresponding SnapMirror policy
associated with the SnapMirror relationship. Snapshot copies that match the same –snapmirror-label will be deleted in
oldest-first order.

For extended data protection (XDP) relationships, the parameter –source-snapshot is optional and only allows for the transfer of Snapshot
copies newer than the common Snapshot copy up to the specified –source-snapshot.

For extended data protection (XDP) relationships the parameter –source-snapshot is optional.

For extended data protection (XDP) relationships with a snapmirror policy of type vault or mirror-vault, the
parameter –source-snapshot allows transfer of a Snapshot copy that is older than the common Snapshot copy and/or may not
be selected for transfer based on policy-based selection of a scheduled update transfer.

For extended data protection (XDP) relationships with a snapmirror policy of type async-mirror, the snapmirror
update with parameter –source-snapshot does not create a new Snapshot copy on the source volume. Depending on the
rules in the policy, the command may transfer just the specified Snapshot copy or Snapshot copies that are newer than
the common Snapshot copy up to and including the specified Snapshot copy. The newly created Snapshot copy is always selected.

After the snapmirror update command successfully completes, the last Snapshot copy transferred is designated as the new
exported Snapshot copy on the destination volume. If an update to an extended data protection (XDP) relationship specifies a
Snapshot copy using the –source-snapshot parameter that is older than the common snapshot, after the snapmirror
update successfully completes, the exported Snapshot copy on the destination volume will remain unchanged.

If the snapmirror update does not finish successfully--for example, due to a network failure or because a snapmirror
abort command was issued--a restart checkpoint might be recorded on the destination volume. If a restart checkpoint is
recorded, the next update restarts and continues the transfer from the restart checkpoint. For extended data protection (XDP)
relationships, the next update will restart and continue the old transfer regardless of whether the Snapshot copy being transferred
is a matching Snapshot copy or not.

If you add an aggregate to the source Infinite Volume, you must also add an aggregate of the same or greater size to the
destination Infinite Volume before any snapmirror update occurs.

This command is supported for SnapMirror relationships with the field “Relationship Capability” showing as either
“8.2 and above” or “Pre 8.2” in the output of the snapmirror show command.

For relationships with “Relationship Capability” of “8.2 and above”, you can track the progress of the operation
using the snapmirror show command.

For relationships with “Relationship Capability” of “Pre 8.2”, a job will be spawned to operate on the SnapMirror
relationship, and the job id will be shown in the command output. The progress of the job can be tracked using the job show
and job history show commands.

For Vserver SnapMirror relationships, the snapmirror update command makes the destination Vserver an up-to-date mirror
of the source Vserver.

The snapmirror update command must be used from the destination Vserver or cluster.
Parameters

{ [-source-path] -S <[vserver:][volume]> | <[cluster://vserver/volume]> | <[hostname:/lun/lun-name]> } - Source Path

Specifies the source endpoint of the SnapMirror relationship in one of two path formats. The normal format includes the names of the Vserver (vserver) and/or volume (volume). To support relationships with "Relationship Capability" of "Pre 8.2", a format which also includes the name of the cluster (cluster) is provided. The "Pre 8.2" format cannot be used when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above".

{ [-source-cluster <Cluster name>] } - Source Cluster

Specifies the source cluster of the SnapMirror relationship. If this parameter is specified, the -source-vserver and -source-volume parameters must also be specified. This parameter is only applicable for relationships with "Relationship Capability" of "Pre 8.2". This parameter cannot be specified when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above".

{ [-source-vserver <vserver name>] } - Source Vserver

Specifies the source Vserver of the SnapMirror relationship. For relationships with volumes as endpoints, if this parameter is specified, parameters -source-volume and for relationships with "Relationship Capability" of "Pre 8.2", -source-cluster must also be specified.

{ [-source-volume <volume name>] } - Source Volume

Specifies the source volume of the SnapMirror relationship. If this parameter is specified, parameters -source-vserver and for relationships with "Relationship Capability" of "Pre 8.2", -source-cluster must also be specified.

{ [-destination-path] -D <[vserver:][volume]> | <[cluster://vserver/volume]> | <[hostname:/lun/lun-name]> } - Destination Path

Specifies the destination endpoint of the SnapMirror relationship in one of two path formats. The normal format includes the names of the Vserver (vserver) and/or volume (volume). To support relationships with "Relationship Capability" of "Pre 8.2", a format which also includes the name of the cluster (cluster) is provided. The "Pre 8.2" format cannot be used when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above".

{ [-destination-cluster <Cluster name>] } - Destination Cluster

Specifies the destination cluster of the SnapMirror relationship. If this parameter is specified, parameters -destination-vserver and -destination-volume must also be specified. This parameter is only applicable for relationships with "Relationship Capability" of "Pre 8.2". This parameter cannot be specified when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above".

-destination-vserver <vserver name> - Destination Vserver

Specifies the destination Vserver of the SnapMirror relationship. For relationships with volumes as endpoints, if this parameter is specified, parameters -destination-volume and for relationships with "Relationship Capability" of "Pre 8.2", -destination-cluster must also be specified.

-destination-volume <volume name> - Destination Volume

Specifies the destination volume of the SnapMirror relationship. If this parameter is specified, parameters -destination-vserver and for relationships with "Relationship Capability" of "Pre 8.2", -destination-cluster must also be specified.

{ [-source-snapshot] -S <text> } - Source Snapshot

This optional parameter specifies a Snapshot copy to transfer. The default behavior for a data protection relationship with a read-write source is that Data ONTAP creates a new Snapshot copy and uses it as the basis for determining what data are replicated; with this option, the specified Snapshot copy will be used instead. The default behavior for an extended data protection relationship depends on the relationship's policy type. For a data protection relationship, the specified Snapshot copy must be newer than the latest common Snapshot copy. For an extended data protection relationship, the specified Snapshot copy may be newer or older than the
common Snapshot copy. This parameter is not supported for relationships with "Relationship Capability" of "Pre 8.2".

[-throttle | -k <throttleType>] - Throttle (KB/sec)
This optional parameter limits the network bandwidth used for the update transfer. It sets the maximum rate (in Kbytes/sec) at which data can be transferred during the operation. If this parameter is not specified, the throttle value configured for the relationship with the snapmirror create or snapmirror modify commands will be used. To specify fully using the network bandwidth available, set the throttle value to unlimited or 0. The minimum throttle value is four Kbytes/sec, so if you specify a throttle value between 1 and 4, it will be treated as if you specified 4. The -throttle parameter does not affect load-sharing transfers and transfers for other relationships with "Relationship Capability" of "Pre 8.2" confined to a single cluster.

[-transfer-priority {low|normal}] - Transfer Priority
This optional parameter specifies the priority at which the transfer runs. The default value for this parameter is the value in the SnapMirror policy associated with this relationship. This parameter is not applicable to relationships with a "Relationship Capability" of "Pre 8.2".

[-enable-storage-efficiency [true]] - Enable Storage Efficient Transfers
This is an optional parameter. For an extended data protection (XDP) relationship that is currently not storage efficient, set this parameter to true to enable storage efficient transfers. Storage efficient in this context refers to both over the wire efficiency and how the data is written to the destination volume. The transfer fails if storage efficiency cannot be achieved. If the transfer succeeds, future transfers will continue being storage efficient as long as it is still feasible, but will not fail if the transfer is not storage efficient. The default value is false.

[-foreground | -w [true]] - Foreground Process
This specifies whether the operation runs as a foreground process. If this parameter is specified, the default setting is true (the operation runs in the foreground). When set to true, the command will not return until the process completes. This parameter is only applicable to relationships with "Relationship Capability" of "Pre 8.2".

Examples
To update the mirror relationship between the destination endpoint vs2.example.com:dept_eng_dp_mirror3 and its source endpoint, type the following command:

```
vs2.example.com::> snapmirror update -destination-path
vs2.example.com:dept_eng_dp_mirror3
```

For relationships with "Relationship Capability" of "Pre 8.2", to update the mirror relationship between the destination endpoint cluster2://vs2.example.com/dept_eng_dp_mirror3 and its source endpoint, type the following command:

```
cluster2::> snapmirror update -destination-path
cluster2://vs2.example.com/dept_eng_dp_mirror3
```

To update the Vserver SnapMirror relationship between destination endpoint dvs1.example.com: and its source endpoint, type the following command:

```
cluster2::> snapmirror update -destination-path
dvs1.example.com:
```

Related references
snapmirror create on page 500
The `snapmirror update-ls-set` command updates a set of load-sharing mirrors. The command makes destination volumes, in the group of load-sharing mirrors, up-to-date mirrors of the source volume.

The key parameter that identifies the set of load-sharing mirrors is the source volume. SnapMirror transfers are performed from the source volume to each of the up-to-date destination volumes in the set of load-sharing mirrors.

The `snapmirror update-ls-set` command performs an incremental transfer to each of the destination volumes. During an incremental transfer, Data ONTAP takes a Snapshot copy on the source volume to capture the current image of the source volume, finds the most recent common Snapshot copy between the source and destination volumes, and incrementally transfers Snapshot copies that are newer than the common Snapshot copy to the destination volume.

**Note:** You still need to use the `snapmirror update-ls-set` command to manually update the set of load-sharing mirrors even if the set only has one destination mirror. The `snapmirror update` command can only be used to bring up to date a specific destination mirror that is lagging to the set.

After an update using the `snapmirror update-ls-set` command successfully completes, the last Snapshot copy transferred is made the new exported Snapshot copy on the destination volumes.

This command is not supported on Infinite Volume SnapMirror relationships.

This command is only supported for SnapMirror relationships with the field "Relationship Capability" showing as "Pre 8.2" in the output of the `snapmirror show` command.

**Parameters**

- `-source-path | -S <[vserver:]volume>|[[cluster://vserver/volume]>|<[hostname:/lun/lun-name]> | Source Path
  Specifies the source endpoint of the SnapMirror relationship in one of two path formats. The normal format includes the names of the Vserver (vserver) and/or volume (volume). To support relationships with "Relationship Capability" of "Pre 8.2", a format which also includes the name of the cluster (cluster) is provided. The "Pre 8.2" format cannot be used when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above".

- `[-source-cluster <Cluster name>] | Source Cluster
  Specifies the source cluster of the SnapMirror relationship. If this parameter is specified, the `-source-vserver` and `-source-volume` parameters must also be specified. This parameter is only applicable for relationships with "Relationship Capability" of "Pre 8.2". This parameter cannot be specified when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above".
-source-vserver <vserver name> - Source Vserver

Specifies the source Vserver of the SnapMirror relationship. For relationships with volumes as endpoints, if this parameter is specified, parameters -source-volume and for relationships with "Relationship Capability" of "Pre 8.2", -source-cluster must also be specified.

-source-volume <volume name> - Source Volume

Specifies the source volume of the SnapMirror relationship. If this parameter is specified, parameters -source-vserver and for relationships with "Relationship Capability" of "Pre 8.2", -source-cluster must also be specified.

[-foreground | -w [true]] - Foreground Process

This specifies whether the operation runs as a foreground process. If this parameter is specified, the default setting is true (the operation runs in the foreground). When set to true, the command will not return until the process completes. This parameter is only applicable to relationships with "Relationship Capability" of "Pre 8.2".

Examples

To update the group of load-sharing mirrors for the source endpoint named //vs1.example.com/dept_eng, type the following command:

```
cluster1::> snapmirror update-ls-set -source-path //vs1.example.com/dept_eng
```

snapmirror config-replication cluster-storage-configuration commands

The cluster-storage-configuration directory

snapmirror config-replication cluster-storage-configuration modify

Modify SnapMirror storage configuration information

Availability: This command is available to cluster administrators at the advanced privilege level.

Description

The snapmirror config-replication cluster-storage-configuration modify command modifies the configuration of storage used for configuration replication.

Parameters

[-disallowed-aggregates <aggregate name>, ...] - Disallowed Aggregates

Use this parameter to set the list of storage aggregates that are not available to host storage for configuration replication.

Examples

The following example disallows two aggregates named aggr1 and aggr2:

### snapmirror config-replication cluster-storage-configuration show

Display SnapMirror storage configuration information

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

**Description**

The `snapmirror config-replication cluster-storage-configuration show` command shows details of the configuration of the storage used for configuration replication.

The information displayed is the following:

- **Disallowed Aggregates** - The list of storage aggregates that are configured as not allowed to host storage areas.
- **Auto-Repair** - Displays `true` if the automatic repair of storage areas used by configuration replication is enabled.
- **Auto-Recreate** - Displays `true` if the automatic recreation of storage volumes used by configuration replication is enabled.
- **Use Mirrored Aggregate** - Displays `true` if storage areas for configuration replication are to be hosted on a mirrored aggregate.

**Examples**

The following is an example of the `snapmirror config-replication cluster-storage-configuration show` command:

```bash
cluster1::*> snapmirror config-replication cluster-storage-configuration show
Disallowed Aggregates: -
Auto-Repair: true
Auto-Recreate: true
Use Mirrored Aggregate: true
```

### snapmirror config-replication status commands

SnapMirror configuration replication status information

### snapmirror config-replication status show

Display SnapMirror configuration replication status information

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**

The `snapmirror config-replication status show` command displays the current SnapMirror configuration replication status.
The command displays the following aspects of SnapMirror configuration replication:

- **Enabled**: Verifies that SnapMirror configuration replication is enabled on the cluster.
- **Running**: Verifies that SnapMirror configuration replication is running on the cluster.
- **Storage Status**: Verifies that SnapMirror configuration replication storage is healthy.
- **Storage In Use**: Prints the location of SnapMirror configuration replication storage.
- **Storage Remarks**: Prints the underlying root cause for non-healthy SnapMirror configuration storage.
- **Vserver Streams**: Verifies that SnapMirror configuration replication Vserver streams are healthy.

Additional information about the warnings (if any) and recovery steps can be viewed by running the command with the `-instance` option.

### Parameters

[-instance ]

If you specify the `-instance` parameter, the command displays detailed information about all fields.

### Examples

The following example shows the execution of the command:

```
clus1::*> snapmirror config-replication status show
Enabled: true
Running: true
Storage Status: ok
Storage In Use: Cluster-wide Volume: MDV_CRS_3d47e9106b7d1e4a77b000c29f810a2_A
Storage Remarks: -
Vserver Streams: ok
```

`snapmirror config-replication status show-aggregate-eligibility`

Display the SnapMirror configuration replication aggregate eligibility

**Availability**: This command is available to cluster administrators at the `admin` privilege level.

**Description**
The `snapmirror config-replication status show-aggregate-eligibility` command displays the SnapMirror configuration replication aggregate eligibility.

**Parameters**

- `[-fields <fieldname>, ...]`
  - If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

- `[-instance ]`
  - If you specify the `-instance` parameter, the command displays detailed information about all fields.

- `[-aggregate <aggregate name>]` - Aggregate
  - Display only rows that have a matching aggregate name.
-hosted-configuration-replication-volumes <volume name>, ...] - Currently Hosted Configuration Replication Volumes
Display only rows that have matching configuration replication volumes hosted on this aggregate.

-is-eligible-to-host-additional-volumes {true|false]} - Eligibility to Host Another Configuration Replication Volume
Display only rows that have a matching eligibility of the aggregate to host additional configuration replication volumes.

-comment <text>] - Comment for Eligibility Status
Display only rows that have a matching comment regarding the eligibility of the aggregate to host configuration replication volumes.

Examples
The following example shows the execution of the command in a SnapMirror configuration with thirteen aggregates in the cluster:

```
clusA::snapmirror config-replication status> show-aggregate-eligibility
Eligible to Aggregate Hosted Config Replication Vols Host Addl Vols Comments

snapmirror config-replication status show on page 569

snapmirror config-replication status show-communication
Display SnapMirror configuration replication communication status information
Availability: This command is available to cluster administrators at the admin privilege level.

Description
The snapmirror config-replication status show-communication command displays the current SnapMirror configuration replication communication status.

The command displays the following aspects of SnapMirror configuration replication for each peer cluster:

- Remote Heartbeat: Verifies that the SnapMirror configuration replication heartbeat with the remote cluster is healthy.
- Last Heartbeat Sent: Prints the timestamp of the last SnapMirror configuration replication heartbeat sent to the remote cluster.
• Last Heartbeat Received: Prints the timestamp of the last SnapMirror configuration replication heartbeat received from the remote cluster.

Additional information about the warnings (if any) and recovery steps can be viewed by running the command with the -instance option.

**Parameters**

```
[-fields <fieldname>, ...]
```

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

```
[-instance]
```

If you specify the `-instance` parameter, the command displays detailed information about all fields.

```
[-cluster-uuid <UUID>] - Remote Cluster
```

Display only rows that have a matching peer cluster UUID.

```
[-cluster <text>] - Peer Cluster Name
```

Display only rows that have matching peer cluster name.

```
[-remote-heartbeat {ok|warning|not-run|not-applicable}] - Remote Heartbeat
```

Display only rows that have a matching remote heartbeat status.

```
[-last-heartbeat-sent <MM/DD/YYYY HH:MM:SS>] - Last Heartbeat Sent Time
```

Display only rows that have a matching timestamp of the last heartbeat sent.

```
[-last-heartbeat-received <MM/DD/YYYY HH:MM:SS>] - Last Heartbeat Received Time
```

Display only rows that have a matching timestamp of the last heartbeat received.

```
[-heartbeat-recovery-steps <text>] - Heartbeat Recovery Steps
```

Display only rows that have matching heartbeat recovery steps.

**Examples**

The following example shows the execution of the command in a SnapMirror configuration with two peer clusters:

```
clus1::*> snapmirror config-replication status show-communication
Peer Cluster: clus2
  Remote Heartbeat: ok
  Last Heartbeat Sent: 11/11/2014 11:11:45
  Last Heartbeat Received: 11/11/2014 11:11:46

  Peer Cluster: clus3
  Remote Heartbeat: ok
  Last Heartbeat Sent: 11/11/2014 11:11:26
  Last Heartbeat Received: 11/11/2014 11:11:27

2 entries were displayed.
```

`snapmirror config-replication status show` on page 569

**snapmirror policy commands**

Manage SnapMirror policies

The `snapmirror policy` command enables you to manage SnapMirror policies.
**snapmirror policy add-rule**

Add a new rule to SnapMirror policy

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

**Description**

The `snapmirror policy add-rule` command adds a rule to a SnapMirror policy. Rules define which Snapshot copies are protected by vault relationships or define the schedule at which Snapshot copies are created on the SnapMirror destination. Rules which do not include a schedule are rules for protecting Snapshot copies. Rules which include a schedule are rules for creating Snapshot copies on the SnapMirror destination. A rule with a schedule can only be added to SnapMirror policies of type *vault* or *mirror-vault*. A rule must not be added to a policy that will be associated with a SnapMirror data protection relationship. A policy that will be associated with a SnapMirror vault relationship must have at least one rule and at most ten rules. A SnapMirror policy with rules must have at least one rule without a schedule.

**Parameters**

- `vserver <vserver name>` - Vserver Name
  
  Specifies the Vserver for the SnapMirror policy.

- `policy <sm_policy>` - SnapMirror Policy Name
  
  Specifies the SnapMirror policy name.

- `snapmirror-label <text>` - Snapshot Copy Label
  
  This parameter is primarily used for the purpose of Snapshot copy selection for extended data protection (XDP) relationships. Only Snapshot copies that have a SnapMirror label that matches this parameter will be transferred to the SnapMirror destination. However, when this parameter is associated with a rule containing a schedule, Snapshot copies will be created on the SnapMirror destination using this `snapmirror-label` parameter. The label can be 31 or fewer characters in length. SnapMirror policies of type *async-mirror* and *mirror-vault* have a rule added for label `sm_created` at the time of policy creation. This rule cannot be removed or modified by the user. This rule when coupled with `create-snapshot` field set to `true` indicates that the SnapMirror relationship using this policy shall create a new Snapshot copy and transfer it as part of a `snapmirror update` operation. SnapMirror policies of type *async-mirror* support one additional rule with SnapMirror label `all_source_snapshots`. This rule along with the rule for SnapMirror label `sm_created` indicates that all new Snapshot copies on the primary volume along with the newly created Snapshot copy are transferred as a part of a `snapmirror update` or `snapmirror initialize` operation. Rules with any other SnapMirror labels cannot be added to SnapMirror policies of type *async-mirror*. The rule for label `sm_created` when added to a `snapmirror policy` of type *vault* indicates that all SnapMirror created Snapshot copies of the primary volume are selected for transfer.

- `keep <text>` - Snapshot Copy Retention Count
  
  Specifies the maximum number of Snapshot copies that are retained on the SnapMirror destination volume for a rule. The total number of Snapshot copies retained for all the rules in a policy cannot exceed 251. For all the rules in SnapMirror policies of type *async-mirror*, this parameter must be set to value 1.

- `[-preserve {true|false}]` - Snapshot Copy Preserve Enabled
  
  Specifies the behavior when the Snapshot copy retention count is reached on the SnapMirror vault destination for the rule. The default value is `false`, which means that the oldest Snapshot copy will be deleted to make room for new ones only if the number of Snapshot copies has exceeded the retention count specified in the "keep" parameter. When set to `true`, and when the Snapshot copies have reached the retention count, then an incremental SnapMirror vault update transfer will fail if or if the rule has a schedule, Snapshot copies will no longer be created on the SnapMirror destination. For all the rules in SnapMirror policies of type *async-mirror* this parameter must be set to value `false`.

- `[-warn <integer>]` - Warning Threshold Count
  
  Specifies the warning threshold count for the rule. The default value is 0. When set to a value greater than zero, an event is generated after the number of Snapshot copies (for the particular rule) retained on a
SnapMirror vault destination reaches the specified warn limit. The preserve parameter for the rule must be 
true to set the warn parameter to a value greater than zero.

[-schedule <text>] - Snapshot Copy Creation Schedule

This optional parameter specifies the name of the schedule associated with a rule. This parameter is allowed 
only for rules associated with SnapMirror policies of type vault or mirror-vault. When this parameter is 
specified, Snapshot copies are directly created on the SnapMirror destination. The Snapshot copies created 
will have the same content as the latest Snapshot copy already present on the SnapMirror destination. 
Snapshot copies on the source that have a SnapMirror label matching this rule will not be selected for transfer. 
The default value is -.

Note: You define and name a schedule using the job schedule cron create command.

[-prefix <text>] - Snapshot Copy Creation Prefix

This optional parameter specifies the prefix for the Snapshot copy name to be created as per the schedule. If no 
value is specified, then the snapmirror-label will be used as the prefix. The prefix parameter can only be 
specified for rules which have a schedule.

Examples

The following example adds a rule named nightly to the SnapMirror policy named TieredBackup on Vserver 
vs0.example.com. The rule will retain a maximum of 5 nightly Snapshot copies.

```
vs0.example.com::> snapmirror policy add-rule -vserver vs0.example.com 
               -policy TieredBackup -snapmirror-label nightly -keep 5
```

The following example adds a rule named SyncProtectMe to the SnapMirror policy named Sync on Vserver 
vs0.example.com. The rule will retain the same SyncProtectMe snapshots on the destination as are present on the 
source when the relationship is InSync.

```
vs0.example.com::> snapmirror policy add-rule -vserver vs0.example.com 
               -policy Sync -snapmirror-label SyncProtectMe -keep 1
```

snapmirror policy create

Create a new SnapMirror policy

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description

The snapmirror policy create command creates a SnapMirror policy. When applied to a SnapMirror relationship, the 
SnapMirror policy controls the behavior of the relationship and specifies the configuration attributes for that relationship. The 
policies DPDefault, MirrorAllSnapshots, MirrorAndVault, MirrorLatest and XDPDefault are created by the system.

Note: All SnapMirror policies have a field create-snapshot. This field specifies whether SnapMirror creates a new 
Snapshot copy on the primary volume at the beginning of a snapmirror update or snapmirror resync operation. 
Currently this field cannot be set or modified by the user. It is set to true for SnapMirror policies of type async-mirror
and mirror-vault at the time of creation. SnapMirror policies of type vault have create-snapshot set to false at the
time of creation.

**Note:** Use the `snapmirror policy add-rule` command to add a rule to a policy.

**Parameters**

- `-vserver <vserver name>` - Vserver Name
  Specifies the Vserver for the SnapMirror policy.

- `-policy <sm_policy>` - SnapMirror Policy Name
  This parameter specifies the SnapMirror policy name. A policy name can be made up of the characters A to Z,
a to z, 0 to 9, ".", ",", and ".". The name can be up to 256 characters in length.

- `[type {vault|async-mirror|mirror-vault}]` - Snapmirror Policy Type
  This parameter specifies the SnapMirror policy type. The supported values are async-mirror, vault and
  mirror-vault. Data protection (DP) relationships support only async-mirror policy type, while extended
data protection (XDP) relationships support all three policy types.

  - If the type is set to async-mirror then the policy is for Disaster Recovery. When the policy type is
    associated with extended data protection (XDP) relationships, `snapmirror update` and `snapmirror
    resync` operations transfer selected Snapshot copies from the primary volume to the secondary volume. The
    selection of Snapshot copies is governed by the rules in the policy. However `snapmirror initialize` and
    `snapmirror update` operations on data protection (DP) relationships ignore the rules in the policy and
    transfer all Snapshot copies of the primary volume which are newer than the common Snapshot copy on the
    destination. For both data protection (DP) and extended data protection (XDP) relationships, the Snapshot
    copies are kept on the secondary volume as long as they exist on the primary volume. Once a protected
    Snapshot copy is deleted from the primary volume, it is deleted from the secondary volume as part of the next
    transfer. The policy type supports rules with certain pre-defined label names only. Refer to the man page for
    the `snapmirror policy add-rule` command for the details.

  - If the type is set to vault then the policy is used for Backup and Archive. The rules in this policy type
    determine which Snapshot copies are protected and how long they are retained on the secondary volume. This
    policy type is supported by extended data protection (XDP) relationships only.

  - If the type is set to mirror-vault then the policy is used for unified data protection which provides both
    Disaster Recovery and Backup using the same secondary volume. This policy type is supported by extended
    data protection (XDP) relationships only.

- `[comment <text>]` - Comment
  Specifies a text comment for the SnapMirror policy. If the comment contains spaces, it must be enclosed
  within quotes.

- `[tries <unsigned32_or_unlimited>]` - Tries Limit
  Determines the maximum number of times to attempt each manual or scheduled transfer for a SnapMirror
  relationship. The value of this parameter must be a positive integer or unlimited. The default value is 8.

- `[transfer-priority {low|normal}]` - Transfer Scheduling Priority
  Specifies the priority at which a transfer runs. The supported values are normal or low. The normal transfers
  are scheduled before the low priority transfers. The default is normal.

- `[ignore-atime {true|false}]` - Ignore File Access Time
  This parameter applies only to extended data protection (XDP) relationships. It specifies whether incremental
  transfers will ignore files which have only their access time changed. The supported values are true or
  false. The default is false.

- `[restart {always|never|default}]` - Restart Behavior
  This parameter applies only to data protection relationships. It defines the behavior of SnapMirror if an
  interrupted transfer exists. The supported values are always, never, or default. If the value is set to
always, an interrupted SnapMirror transfer always restarts provided it has a restart checkpoint and the conditions are the same as they were before the transfer was interrupted. In addition, a new SnapMirror Snapshot copy is created which will then be transferred. If the value is set to never, an interrupted SnapMirror transfer will never restart, even if a restart checkpoint exists. A new SnapMirror Snapshot copy will still be created and transferred. Data ONTAP version 8.2 will interpret a value of default as being the same as always. Vault transfers will always resume based on a restart checkpoint, provided the Snapshot copy still exists on the source volume.

[-is-network-compression-enabled (true|false)] - Is Network Compression Enabled
Specifications whether network compression is enabled for transfers. The supported values are true or false. The default is false.

[-discard-configs <network>, ...] - Configurations Not Replicated During Identity Preserve Vserver DR
Specifications the configuration to be dropped during replication. The supported values are:

• network - Drops network interfaces, routes, and kerberos configuration.

This parameter is supported only for policies of type async-mirror and applicable only for identity-preserve Vserver SnapMirror relationships.

Examples
The following example creates a SnapMirror policy named TieredBackup on a Vserver named vs0.example.com.

vs0.example.com::> snapmirror policy create -vserver vs0.example.com
-policy TieredBackup -type vault -tries 10 -restart never

The following example executed under PVR control creates a SnapMirror policy named Sync on a Vserver named vs0.example.com with -always-replicate_snapshots set to true to be used for a relationship between items in Consistency Groups.

vs0.example.com::> snapmirror policy create -vserver vs0.example.com
-policy Sync -type sync-mirror -always-replicate-snapshots true

snapmirror policy delete
Delete a SnapMirror policy

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The snapmirror policy delete command deletes a SnapMirror policy. A policy that is to be deleted must not be associated with any SnapMirror relationship. The default policies DPDefault and XDPDefault cannot be deleted.
Parameters

-vserver <vserver name> - Vserver Name
  Specifies the Vserver for the SnapMirror policy.

-policy <sm_policy> - SnapMirror Policy Name
  Specifies the SnapMirror policy name.

Examples

The following example deletes a SnapMirror policy named TieredBackup on Vserver vs0.example.com:

vs0.example.com::> snapmirror policy delete -vserver vs0.example.com
               -policy TieredBackup

snapmirror policy modify

Modify a SnapMirror policy

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description

The snapmirror policy modify command can be used to modify the policy attributes.

Note: Use the snapmirror policy modify-rule command to modify a rule in a SnapMirror policy.

Parameters

-vserver <vserver name> - Vserver Name
  Specifies the Vserver for the SnapMirror policy.

-policy <sm_policy> - SnapMirror Policy Name
  Specifies the SnapMirror policy name.

[-comment <text>] - Comment
  Specifies a text comment for the SnapMirror policy. If the comment contains spaces, it must be enclosed within quotes.

[-tries <unsigned32_or_unlimited>] - Tries Limit
  Determines the maximum number of times to attempt each manual or scheduled transfer for a SnapMirror relationship. The value of this parameter must be a positive integer or unlimited. The default value is 8.

[-transfer-priority (low|normal)] - Transfer Scheduling Priority
  Specifies the priority at which a transfer runs. The supported values are normal or low. The normal transfers are scheduled before the low priority transfers. The default is normal.

[-ignore-atime {true|false}] - Ignore File Access Time
  This parameter applies only to extended data protection (XDP) relationships. It specifies whether incremental transfers will ignore files which have only their access time changed. The supported values are true or false. The default is false.

[-restart {always|never|default}] - Restart Behavior
  This parameter applies only to data protection relationships. It defines the behavior of SnapMirror if an interrupted transfer exists. The supported values are always, never, or default. If the value is set to always, an interrupted SnapMirror transfer always restarts provided it has a restart checkpoint and the conditions are the same as they were before the transfer was interrupted. In addition, a new SnapMirror Snapshot copy is created which will then be transferred. If the value is set to never, an interrupted SnapMirror transfer will never restart, even if a restart checkpoint exists. A new SnapMirror Snapshot copy will still be created and transferred. Data ONTAP version 8.2 will interpret a value of default as being the
same as always. Vault transfers will always resume based on a restart checkpoint, provided the Snapshot copy still exists on the source volume.

**[-is-network-compression-enabled \{true|false\}] - Is Network Compression Enabled**

Specifies whether network compression is enabled for transfers. The supported values are true or false. The default is false.

**[-discard-configs <network>, ...] - Configurations Not Replicated During Identity Preserve Vserver DR**

Specifies the configuration to be dropped during replication. The supported values are:

- network - Drops network interfaces, routes, and kerberos configuration.

This parameter is supported only for policies of type async-mirror and applicable only for identity-preserve Vserver SnapMirror relationships.

### Examples

The following example changes the "transfer-priority" and the "comment" text of a snapmirror policy named TieredBackup on Vserver vs0.example.com:

```
vs0.example.com::> snapmirror policy modify -vserver vs0.example.com -policy TieredBackup -transfer-priority low -comment "Use for tiered backups"
```

### snapmirror policy modify-rule

Modify an existing rule in SnapMirror policy

**Availability:** This command is available to cluster and Vserver administrators at the admin privilege level.

**Description**

The snapmirror policy modify-rule command can be used to modify the retention count, preserve setting, warning threshold count, schedule, and prefix for a rule in a SnapMirror policy. Reducing the retention count or disabling the preserve setting for a rule in a SnapMirror policy might result in the deletion of Snapshot copies on the vault destination when the next transfer by the snapmirror update command occurs or when the next scheduled Snapshot copy creation on the destination for the rule occurs. Modifying a rule to add a schedule will enable creation of Snapshot copies on the SnapMirror destination. Snapshot copies on the source that have a SnapMirror label matching this rule will not be selected for transfer. Schedule and prefix can only be modified for rules associated with SnapMirror policies of type vault or mirror-vault. A SnapMirror policy with rules must have at least one rule without a schedule.

**Note:** The rules in SnapMirror policies of type async-mirror cannot be modified.

**Parameters**

- **vserver <vserver name> - Vserver Name**
  
  Specifies the Vserver for the SnapMirror policy.

- **policy <sm_policy> - SnapMirror Policy Name**
  
  Specifies the SnapMirror policy name.
-snapmirror-label <text> - Snapshot Copy Label

This parameter specifies the rule that is to be modified in a SnapMirror policy.

-keep <text> - Snapshot Copy Retention Count

Specifies the maximum number of Snapshot copies that are retained on the SnapMirror destination volume for a rule. The total number of Snapshot copies retained for all the rules in a policy cannot exceed 251. For all the rules in SnapMirror policies of type async-mirror, this parameter must be set to value 1.

-preserve {true|false} - Snapshot Copy Preserve Enabled

Specifies the behavior when the Snapshot copy retention count is reached on the SnapMirror vault destination for the rule. The default value is false, which means that the oldest Snapshot copy will be deleted to make room for new ones only if the number of Snapshot copies has exceeded the retention count specified in the "keep" parameter. When set to true, and when the Snapshot copies have reached the retention count, then an incremental SnapMirror vault update transfer will fail or if the rule has a schedule, Snapshot copies will no longer be created on the SnapMirror destination. For all the rules in SnapMirror policies of type async-mirror this parameter must be set to value false.

-warn <integer> - Warning Threshold Count

Specifies the warning threshold count for the rule. The default value is 0. When set to a value greater than zero, an event is generated after the number of Snapshot copies (for the particular rule) retained on a SnapMirror vault destination reaches the specified warn limit. The preserve parameter for the rule must be true to set the warn parameter to a value greater than zero.

-schedule <text> - Snapshot Copy Creation Schedule

This optional parameter specifies the name of the schedule associated with a rule. This parameter is allowed only for rules associated with SnapMirror policies of type vault or mirror-vault. When this parameter is specified, Snapshot copies are directly created on the SnapMirror destination. The Snapshot copies created will have the same content as the latest Snapshot copy already present on the SnapMirror destination. Snapshot copies on the source that have a SnapMirror label matching this rule will not be selected for transfer. The default value is -.

Note: You define and name a schedule using the job schedule cron create command.

-prefix <text> - Snapshot Copy Creation Prefix

This optional parameter specifies the prefix for the Snapshot copy name to be created as per the schedule. If no value is specified, then the snapmirror-label will be used as the prefix. The prefix parameter can only be specified for rules which have a schedule.

Examples

The following example changes the retention count for nightly Snapshot copies to 6 for a rule named nightly on a SnapMirror policy named TieredBackup on Vserver vs0.example.com:

```
vs0.example.com::> snapmirror policy modify-rule -vserver vs0.example.com
  -policy TieredBackup -snapmirror-label nightly -keep 6
```

snapmirror policy remove-rule

Remove a rule from SnapMirror policy

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.
Description
The snapmirror policy remove-rule command removes a rule from a SnapMirror policy. On the destination of a SnapMirror relationship with snapmirror policy of type vault or mirror-vault, all Snapshot copies with a SnapMirror label matching the rule being removed are no longer processed by SnapMirror and might need to be deleted manually. A snapmirror policy of type vault must have at least one rule if that policy is associated with a SnapMirror relationship. A SnapMirror policy with rules must have at least one rule without a schedule.

Parameters
-vserver <vserver name> - Vserver Name
   Specifies the Vserver for the SnapMirror policy.
-policy <sm_policy> - SnapMirror Policy Name
   Specifies the SnapMirror policy name.
-snapmirror-label <text> - Snapshot Copy Label
   This parameter specifies the rule that is removed from the SnapMirror policy.
   The rule for SnapMirror label sm_created cannot be removed from SnapMirror policies of type async-mirror or mirror-vault.

Examples
The following example removes a rule named nightly from a SnapMirror policy named TieredBackup on Vserver vs0.example.com:

   vs0.example.com::> snapmirror policy remove-rule -vserver vs0.example.com -policy TieredBackup -snapmirror-label nightly

snapmirror policy on page 572

snapmirror policy show
Show SnapMirror policies

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The snapmirror policy show command displays the following information about SnapMirror policies:

- Vserver Name
- SnapMirror Policy Name
- SnapMirror Policy Type
- Number of Rules in the policy
- Tries
- Transfer Priority
- Comment for the policy
- Individual Rule Names
- Keep value for the Rule
- Total of Keep values across all Rules in the policy
Parameters

{[-fields <fieldname>, ... ]}

If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use -fields ? to display the fields to specify.

{[-instance ]}

If you specify the -instance parameter, the command displays detailed information about all fields.

[-vserver <vserver name>] - Vserver Name

Selects the policies that match this parameter value.

[-policy <sm_policy>] - SnapMirror Policy Name

Selects the policies that match this parameter value.

[-type {vault|async-mirror|mirror-vault}] - Snapmirror Policy Type

Selects the policies that match this parameter value. A policy can be of type async-mirror, vault or mirror-vault.

[-owner {cluster-admin|vserver-admin}] - Owner of the Policy

Selects the policies that match this parameter value. A policy can be owned by either the "Cluster Admin" or a "Vserver Admin".

[-comment <text>] - Comment

Selects the policies that match this parameter value.

[-tries <unsigned32_or_unlimited>] - Tries Limit

Selects the policies that match this parameter value.

[-transfer-priority {low|normal}] - Transfer Scheduling Priority

Selects the policies that match this parameter value.

[-ignore-atime {true|false}] - Ignore File Access Time

Selects the policies that match this parameter value.

[-restart {always|never|default}] - Restart Behavior

Selects the policies that match this parameter value.

[-is-network-compression-enabled {true|false}] - Is Network Compression Enabled

Selects the policies that match this parameter value.

[-create-snapshot {true|false}] - Create a New Snapshot Copy

Selects the policies that match this parameter value.

[-snapmirror-label <text>, ...] - Snapshot Copy Label

Selects the policies that match this parameter value.

[-keep <text>, ...] - Snapshot Copy Retention Count

Selects the policies that match this parameter value.

[-preserve {true|false}, ...] - Snapshot Copy Preserve Enabled

Selects the policies that match this parameter value.

[-warn <integer>, ...] - Warning Threshold Count

Selects the policies that match this parameter value.

[-schedule <text>, ...] - Snapshot Copy Creation Schedule

Selects the policies that match this parameter value.

[-prefix <text>, ...] - Snapshot Copy Creation Prefix

Selects the policies that match this parameter value.
[-total-rules <integer>] - Total Rules in the Policy
Selects the policies that match this parameter value.

[-total-keep <integer>] - Total Retention Count for All Rules in the Policy
Selects the policies that match this parameter value.

[-discard-configs <network>, ...] - Configurations Not Replicated During Identity Preserve Vserver DR
Selects the policies that match this parameter value.

### Examples
The following example displays information about all SnapMirror policies:

```
cs::> snapmirror policy show
Vserver Policy             Policy Number         Transfer
Name    Name               Type   Of Rules Tries Priority Comment
------- ------------------ ------ -------- ----- -------- ----------
cs      DPDefault          async-mirror  1     8  normal  Default policy for DP relationship.
    SnapMirror Label: sm_created               Keep:       1
                        Total Keep:       1

cs      MirrorAllSnapshots async-mirror  2     8  normal  Asynchronous SnapMirror policy for
    mirroring all snapshots and the latest active file system.
    SnapMirror Label: sm_created               Keep:       1
                        all_source_snapshots 1
                        Total Keep:       2

cs      MirrorAndVault     mirror-vault  3     8  normal  A unified Asynchronous SnapMirror and
    SnapVault policy for mirroring the latest active file system and daily and weekly snapshots.
    SnapMirror Label: sm_created               Keep:       1
                        daily 7
                        weekly 52
                        Total Keep:       60

cs      MirrorLatest       async-mirror  1     8  normal  Asynchronous SnapMirror policy for
    mirroring the latest active file system.
    SnapMirror Label: sm_created               Keep:       1
                        Total Keep:       1

cs      XDPDefault         vault         2     8  normal  Default policy for XDP relationship with
    daily and weekly rules.
    SnapMirror Label: daily weekly               Keep:       ?
                        Total Keep:       ?

vs0.example.com
    TieredBackup       vault 0     8 normal  Use for tiered backups
    Snapmirror-label: -               Keep:       -
                        Total Keep:       0

6 entries were displayed.
```

The following example shows all the policies with the following fields - vserver (default), policy (default) and transfer-priority:

```
cs::> snapmirror policy show -fields transfer-priority
vserver     policy    transfer-priority
------------- --------- -----------------
cs          DPDefault normal

cs          XDPDefault normal

vs0.example.com
    TieredBackup       vault 0     8 normal  Use for tiered backups
    Snapmirror-label: -               Keep:       -
                        Total Keep:       0

3 entries were displayed.
```
snapmirror snapshot-owner commands

Manage Snapshot Copy Preservation

The `snapmirror snapshot-owner` command enables management of user-created owners for a Snapshot copy.

**snapmirror snapshot-owner create**

Add an owner to preserve a Snapshot copy for a SnapMirror mirror-to-vault cascade configuration

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

**Description**
The `snapmirror snapshot-owner create` command adds an owner on the specified Snapshot copy. A Snapshot copy can have at most one owner. An owner can only be added to a Snapshot copy on a read-write volume. The Snapshot copy must have a valid SnapMirror label.

**Note:** Refer to the *ONTAP Data Protection Guide* for valid use cases to add an owner on a Snapshot copy.

**Parameters**
- `-vserver <vserver name>` - Vserver Name
  This parameter specifies the Vserver on which the volume is located.
- `-volume <volume name>` - Volume Name
  This parameter specifies the name of the volume.
- `-snapshot <snapshot name>` - Snapshot Copy Name
  This parameter specifies the name of the Snapshot copy.
- `[ -owner <owner name> ]` - Snapshot Copy Owner Name
  This parameter specifies the name of the owner for the Snapshot copy. The owner name can be made up of the characters A to Z, a to z, 0 to 9, and "_". The name can be up to 32 characters in length. When not specified, an owner will be added with a system-generated default name.

**Examples**
The following example adds owner *app1* on Snapshot copy *snap1* on volume *vol1* in Vserver *vs0.example.com*.

```
cluster1::> snapmirror snapshot-owner create -vserver vs0.example.com -volume vol1 -snapshot snap1 -owner app1
```

The following example adds a default owner on Snapshot copy *snap2* on volume *vol1* in Vserver *vs0.example.com*.

```
cluster1::> snapmirror snapshot-owner create -vserver vs0.example.com -volume vol1 -snapshot snap2
```

**snapmirror snapshot-owner delete**

Delete an owner used to preserve a Snapshot copy for a SnapMirror mirror-to-vault cascade configuration

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

**Description**
The `snapmirror snapshot-owner delete` command removes an owner on the specified Snapshot copy, which was added using the `snapmirror snapshot-owner create` command.
Parameters
-vserver <vserver name> - Vserver Name
   This parameter specifies the Vserver on which the volume is located.
-volume <volume name> - Volume Name
   This parameter specifies the name of the volume.
-snapshot <snapshot name> - Snapshot Copy Name
   This parameter specifies the name of the Snapshot copy.
[-owner <owner name>] - Snapshot Copy Owner Name
   This parameter specifies the name of the owner for the Snapshot copy. When not specified, the owner with the system-generated default name will be removed.

Examples
The following example removes owner appl on Snapshot copy snap1 on volume vol1 in Vserver vs0.example.com.

   cluster1::> snapmirror snapshot-owner delete -vserver vs0.example.com
                -volume vol1 -snapshot snap1 -owner appl

The following example removes the default owner on Snapshot copy snap2 on volume vol1 in Vserver vs0.example.com.

   cluster1::> snapmirror snapshot-owner delete -vserver vs0.example.com
                -volume vol1 -snapshot snap2

snapmirror snapshot-owner show
Display Snapshot Copies with Owners

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The snapmirror snapshot-owner show command is used to list all Snapshot copies with owners that were added using the snapmirror snapshot-owner create command.

Parameters
{} [-fields <fieldname>,...]
   If this parameter is specified, the command displays information about the specified fields.
[-instance]
   If this parameter is specified, the command displays detailed information about all fields.
-vserver <vserver name> - Vserver Name
   This parameter specifies the Vserver on which the volume is located.
-volume <volume name> - Volume Name
   This parameter specifies the name of the volume.
[-snapshot <snapshot name>] - Snapshot Copy Name
   If this parameter is specified, the command displays the owner name for the specified Snapshot copy.
Examples
The following example lists all Snapshot copies with owners on volume vol1 in Vserver vs0. The system-generated default owner name is displayed as ".".

```
cluster1::> snapmirror snapshot-owner show
-vserver vs0.example.com -volume vol1
Vserver          Volume       Snapshot     Owner Names
--------          ------------- -------- -------------------
vs0.example.com   vol1          snap2       -
                 snap1          app1
```

The following example displays the owner name for Snapshot copy snap1 on volume vol1 in Vserver vs0.example.com.

```
cluster1::> snapmirror snapshot-owner show
-vserver vs0.example.com -volume vol1 -snapshot snap1
Vserver: vs0.example.com
Volume: vol1
Snapshot: snap1
Owner Names: app1
```

statistics-v1 commands
Display operational statistics

statistics-v1 protocol-request-size commands
The protocol-request-size directory

statistics-v1 protocol-request-size show
Display size statistics for CIFS and NFS protocol read and write requests

Availability: This command is available to cluster administrators at the admin privilege level.

Description
This command displays size statistics for CIFS and NFS protocol read and write requests. The output of the command includes the following information:

- Node name
- Statistic type
- Average size of request
- Total request count
- Current number of requests in each category of request size
- Number of requests after the command was last executed
Parameters

\{-fields <fieldname>, ...\}

If you specify the \{-fields <fieldname>, ...\} parameter, the command output also includes the specified field or fields. You can use \{-fields ?\} to display the fields to specify.

\{-instance\}

If you specify the \{-instance\} parameter, the command displays detailed information about all fields.

\{-node \{<nodename>|local\}\} - Node

If this parameter is specified, the command displays statistics only for the specified node.

\{-stat-type <Protocol Type>\} - RW Request Stat Type

If this parameter is specified, the command displays only the statistics of the specified protocol type. Protocol types include the following: cifs_read, cifs_write, nfs2_read, nfs2_write, nfs3_read, and nfs3_write.

\{-total-req-count <Counter64 with Delta>\} - Total Request Count

If this parameter is specified, the command displays only statistics with the specified total number of requests.

\{-average-size <Counter64 with Delta>\} - Average Request Size

If this parameter is specified, the command displays only statistics with the specified average request size.

\{-histo08 <Counter64 with Delta>\} - 0 - 511

If this parameter is specified, the command displays only statistics with the specified number of requests in this size range.

\{-histo09 <Counter64 with Delta>\} - 512 - 1023

If this parameter is specified, the command displays only statistics with the specified number of requests in this size range.

\{-histo10 <Counter64 with Delta>\} - 1024 - 2047

If this parameter is specified, the command displays only statistics with the specified number of requests in this size range.

\{-histo11 <Counter64 with Delta>\} - 2048 - 4096

If this parameter is specified, the command displays only statistics with the specified number of requests in this size range.

\{-histo12 <Counter64 with Delta>\} - 4096 - 8191

If this parameter is specified, the command displays only statistics with the specified number of requests in this size range.

\{-histo13 <Counter64 with Delta>\} - 8192 - 16K

If this parameter is specified, the command displays only statistics with the specified number of requests in this size range.

\{-histo14 <Counter64 with Delta>\} - 16K - 32K

If this parameter is specified, the command displays only statistics with the specified number of requests in this size range.

\{-histo15 <Counter64 with Delta>\} - 32K - 64K

If this parameter is specified, the command displays only statistics with the specified number of requests in this size range.

\{-histo16 <Counter64 with Delta>\} - 64K - 128K

If this parameter is specified, the command displays only statistics with the specified number of requests in this size range.

\{-histo17 <Counter64 with Delta>\} - Greater than 128K

If this parameter is specified, the command displays only statistics with the specified number of requests in this size range.
### Examples

The following example displays the number of NFS v3 requests in each size range for only one node in the cluster.

```bash
cluster1::> statistics protocol-request-size show -stat-type nfs3_* -node node0
```

<p>| Node:  | node0 |</p>

### statistics-v1 nfs commands

**Monitor NFS statistics**

**statistics-v1 nfs show-mount**

Display mount statistics

**Availability:** This command is available to cluster administrators at the advanced privilege level.

**Description**

The `statistics-v1 nfs show-mount` command displays the following statistics about the NFS mounts on each node in the cluster:

- Result of the operations (success or failure)
- Total number of null operations
- Total number of mount operations
- Total number of dump operations
- Total number of unmount operations
- Total number of unmountall operations
- Total number of export operations
- Total number of exportall operations
- Total number of pathconf operations
- Total number of all the above operations

This command is designed to be used to analyze performance characteristics and to help diagnose issues.

Parameters

\{ [\textit{-fields <fieldname>,...}] \}

If you specify the \textit{-fields <fieldname>,...} parameter, the command output also includes the specified field or fields. You can use \textit{-fields ?} to display the fields to specify.

\{ [\textit{-instance}] \}

If you specify the \textit{-instance} parameter, the command displays detailed information about all fields.

\{ [\textit{-node <nodename>|local}] - Node \}

If you specify this parameter, the command displays statistics only for the specified node.

\{ [\textit{-result success|failure|all}] - Result \}

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified result (success/failure/all).

\{ [\textit{-null <Counter with Delta>]} - Null Operations \}

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of null operations.

\{ [\textit{-mount <Counter with Delta>]} - Mount Operations \}

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of mount operations.

\{ [\textit{-dump <Counter with Delta>]} - Dump Operations \}

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of dump operations.

\{ [\textit{-unmnt <Counter with Delta>]} - UnMount Operations \}

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of unmount operations.

\{ [\textit{-unmntall <Counter with Delta>]} - UnMountAll Operations \}

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of unmountall operations.

\{ [\textit{-export <Counter with Delta>]} - Export Operations \}

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of export operations.

\{ [\textit{-exportall <Counter with Delta>]} - ExportAll Operations \}

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of exportall operations.

\{ [\textit{-pathconf <Counter with Delta>]} - PathConf Operations \}

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of pathconf operations.
### Examples

The following example displays statistics about the NFS mounts for a node named node1:

```bash
cluster1::*> statistics-v1 nfs show-mount -node node1
```

<table>
<thead>
<tr>
<th>Node</th>
<th>Value</th>
<th>Delta</th>
</tr>
</thead>
<tbody>
<tr>
<td>node1</td>
<td></td>
<td>success -------</td>
</tr>
<tr>
<td>Null Ops:</td>
<td>2</td>
<td>0/s:16s</td>
</tr>
<tr>
<td>Mount Ops:</td>
<td>1</td>
<td>0/s:16s</td>
</tr>
<tr>
<td>Dump Ops:</td>
<td>0</td>
<td>-</td>
</tr>
<tr>
<td>Unmount Ops:</td>
<td>1</td>
<td>0/s:16s</td>
</tr>
<tr>
<td>Unmount All Ops:</td>
<td>0</td>
<td>-</td>
</tr>
<tr>
<td>Export Ops:</td>
<td>0</td>
<td>-</td>
</tr>
<tr>
<td>ExportAll Ops</td>
<td>0</td>
<td>-</td>
</tr>
<tr>
<td>PathConf Ops:</td>
<td>0</td>
<td>-</td>
</tr>
<tr>

### statistics-v1 nfs show-nlm

(DEPRECATED)-Display NLM statistics

**Availability:** This command is available to cluster administrators at the advanced privilege level.

**Description**

The `statistics-v1 nfs show-nlm` command displays the following statistics about the Network Lock Manager (NLM) on each node in the cluster:

- Result of the operations (success or failure)
- Total number of null operations
- Total number of test operations
- Total number of lock operations
- Total number of cancel operations
- Total number of unlock operations
- Total number of granted operations
- Total number of share operations
- Total number of unshare operations
- Total number of nmlock operations
- Total number of freeall operations
• Total number of all the above operations

This command is designed to be used to analyze performance characteristics and to help diagnose issues.

Note: This command requires an effective cluster version earlier than Data ONTAP 9.0. Data for nodes running Data ONTAP 9.0 or later is not collected, and will not be displayed. Use the statistics show-object nlm command instead.

Parameters

{[-fields <fieldname>, ...]
   If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use ‘-fields?’ to display the fields to specify.

[[-instance]]
   If you specify the -instance parameter, the command displays detailed information about all fields.

[-node <nodename>|local] - Node
   If you specify this parameter, the command displays statistics only for the specified node.

[-result {success|failure|all}] - Result
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified result (success/failure/all).

[-null <Counter with Delta>] - Null Operations
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of null operations.

[-test <Counter with Delta>] - Test Operations
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of test operations.

[-lock <Counter with Delta>] - Lock Operations
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of lock operations.

[-cancel <Counter with Delta>] - Cancel Operations
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of cancel operations.

[-unlock <Counter with Delta>] - Unlock Operations
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of unlock operations.

[-granted <Counter with Delta>] - Granted Operations
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of granted operations.

[-share <Counter with Delta>] - Share Operations
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of share operations.

[-unshare <Counter with Delta>] - Unshare Operations
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of unshare operations.

[-nmlock <Counter with Delta>] - NmLock Operations
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of nmlock operations.
[-freeall <Counter with Delta>] - FreeAll Operations

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of freeall operations.

[-total <Counter64 with Delta>] - Total Operations

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of total operations.

Examples

The following example displays statistics about the NLM for a node named node1:

```
cluster1:/> statistics-v1 nfs show-nlm -node node1

Node      Value         Delta
node1     --------success-------
Null:      0             -
Test:      0             -
Lock:      2             0/s:23s
Cancel:    0             -
Unlock:    1             0/s:23s
Granted:   0             -
Share:     0             -
Unshare:   0             -
NmLock:    0             -
FreeAll:   0             -
Total:     3             0/s:23s

Node      Value         Delta
node1     --------failure-------
Null:      0             -
Test:      0             -
Lock:      0             -
Cancel:    0             -
Unlock:    0             -
Granted:   0             -
Share:     0             -
Unshare:   0             -
NmLock:    0             -
FreeAll:   0             -
Total:     0             -
```

statistics-v1 nfs show-statusmon

Display status monitor statistics

Availability: This command is available to cluster administrators at the advanced privilege level.

Description

The statistics-v1 nfs show-statusmon command displays the following statistics about the Status Monitor on each node in the cluster:

- Result of the operations (success or failure)
- Total number of null operations
- Total number of stat operations
- Total number of monitor operations
- Total number of unmonitor operations
• Total number of unmonitor all operations
• Total number of simucrash operations
• Total number of notify operations
• Total number of all the above operations

This command is designed to be used to analyze performance characteristics and to help diagnose issues.

**Parameters**

```plaintext
\{ [-fields <fieldname>,...] \\
  If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use `-fields ?' to display the fields to specify.

|-instance ]
  If you specify the -instance parameter, the command displays detailed information about all fields.

|-node {<nodename>|local]} - Node
  If you specify this parameter, the command displays statistics only for the specified node.

|-result {success|failure|all]} - Result
  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified result (success/failure/all).

|-null <Counter with Delta>] - Null Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of null operations.

|-stat <Counter with Delta>] - Stat Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of stat operations.

|-monitor <Counter with Delta>] - Monitor Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of monitor operations.

|-unmonitor <Counter with Delta>] - Unmonitor Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of unmonitor operations.

|-unmonall <Counter with Delta>] - Unmonitor All Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of unmonitor all operations.

|-simucrash <Counter with Delta>] - SimuCrash Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of simucrash operations.

|-notify <Counter with Delta>] - Notify Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of notify operations.

|-total <Counter64 with Delta>] - Total Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of total operations.
```

**statistics-v1 nfs show-v3**

Display NFSv3 statistics

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**

The `statistics-v1 nfs show-v3` command displays the following statistics about the NFSv3 operations on each node in the cluster:

- Result of the operations (success or failure)
- Total number of null operations
- Total number of getattr operations
- Total number of setattr operations
- Total number of lookup operations
- Total number of access operations
- Total number of readsymlink operations
- Total number of read operations
- Total number of write operations
- Total number of create operations
- Total number of mkdir operations
- Total number of symlink operations
- Total number of mknod operations
- Total number of remove operations
- Total number of rmdir operations
- Total number of rename operations
• Total number of link operations
• Total number of readdir operations
• Total number of readdirplus operations
• Total number of fsstat operations
• Total number of fsinfo operations
• Total number of pathconf operations
• Total number of commit operations
• Total number of nfsv3 operations
• Percent of null operations
• Percent of getattr operations
• Percent of setattr operations
• Percent of lookup operations
• Percent of access operations
• Percent of readdir operations
• Percent of readdirplus operations
• Percent of pathconf operations
• Percent of readdir operations
• Percent of readdirplus operations
• Percent of fsstat operations
• Percent of fsinfo operations
• Percent of pathconf operations
• Percent of commit operations

This command is designed to be used to analyze performance characteristics and to help diagnose issues.
Parameters

{ [-fields <fieldname>, ...]  
  If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

|[-instance ]]  
  If you specify the -instance parameter, the command displays detailed information about all fields.

[-node (<nodename>|local)] - Node  
  If you specify this parameter, the command displays NFSv3 statistics only for the specified node.

[-result (success|failure|all)] - Result  
  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified result (success/failure/all).

[-null <Counter with Delta>] - Null Operations  
  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of null operations.

[-getattr <Counter with Delta>] - GetAttr Operations  
  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of getattr operations.

[-setattr <Counter with Delta>] - SetAttr Operations  
  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of setattr operations.

[-lookup <Counter with Delta>] - LookUp Operations  
  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of lookup operations.

[-access <Counter with Delta>] - Access Operations  
  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of access operations.

[-rsm <Counter with Delta>] - ReadSymlink Operations  
  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of readsymlink operations.

[-read <Counter with Delta>] - Read Operations  
  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of read operations.

[-write <Counter with Delta>] - Write Operations  
  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of write operations.

[-create <Counter with Delta>] - Create Operations  
  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of create operations.

[-mkdir <Counter with Delta>] - MkDir Operations  
  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of mkdir operations.

[-symln <Counter with Delta>] - SymLink Operations  
  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of symlink operations.
[-mknod <Counter with Delta>] - MkNod Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of mknod operations.

[-remove <Counter with Delta>] - Remove Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of remove operations.

[-rmdir <Counter with Delta>] - RmDir Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of rmdir operations.

[-rename <Counter with Delta>] - Rename Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of rename operations.

[-link <Counter with Delta>] - Link Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of link operations.

[-rdir <Counter with Delta>] - ReadDir Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of readdir operations.

[-rdirp <Counter with Delta>] - ReadDirPlus Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of readdirplus operations.

[-fsstat <Counter with Delta>] - FsStat Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of fsstat operations.

[-fsinfo <Counter with Delta>] - FsInfo Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of fsinfo operations.

[-pconf <Counter with Delta>] - PathConf Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of pathconf operations.

[-commit <Counter with Delta>] - Commit Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of commit operations.

[-total <Counter64 with Delta>] - Total Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of total NFSv3 operations.

[-null-pct <Counter with Delta>] - Percent Null Ops
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of null operations.

[-gattr-pct <Counter with Delta>] - Percent GetAttr Ops
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of getattr operations.

[-sattr-pct <Counter with Delta>] - Percent SetAttr Ops
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of setattr operations.
[lookup-pct <Counter with Delta>] - Percent LookUp Ops
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of lookup operations.

[access-pct <Counter with Delta>] - Percent Access Ops
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of access operations.

[rsym-pct <Counter with Delta>] - Percent ReadSymlink Ops
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of readsymlink operations.

[read-pct <Counter with Delta>] - Percent Read Ops
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of read operations.

[write-pct <Counter with Delta>] - Percent Write Ops
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of write operations.

[create-pct <Counter with Delta>] - Percent Create Ops
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of create operations.

[mkdir-pct <Counter with Delta>] - Percent MkDir Ops
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of mkdir operations.

[symln-pct <Counter with Delta>] - Percent SymLink Ops
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of symlink operations.

[mknod-pct <Counter with Delta>] - Percent MkNod Ops
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of mknod operations.

[remove-pct <Counter with Delta>] - Percent Remove Ops
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of remove operations.

[rmdir-pct <Counter with Delta>] - Percent RmDir Ops
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of rmdir operations.

[rename-pct <Counter with Delta>] - Percent Rename Ops
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of rename operations.

[link-pct <Counter with Delta>] - Percent Link Ops
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of link operations.

[rdir-pct <Counter with Delta>] - Percent ReadDir Ops
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of readdir operations.

[rdirp-pct <Counter with Delta>] - Percent ReadDirPlus Ops
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of readdirplus operations.
[-fsstat-pct <Counter with Delta>] - Percent FsStat Ops
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of fsstat operations.

[-fsinfo-pct <Counter with Delta>] - Percent FsInfo Ops
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of fsinfo operations.

[-pconf-pct <Counter with Delta>] - Percent PathConf Ops
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of pathconf operations.

[-commit-pct <Counter with Delta>] - Percent Commit Ops
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of commit operations.

Examples

The following example displays statistics about the NFSv3 operations for a node named node1:

cluster1::> statistics-v1 nfs show-v3 -node node1

statistics-v1 nfs show-v4

Display NFSv4 statistics

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The statistics-v1 nfs show-v4 command displays the following statistics about the NFSv4 operations on each node in the cluster:

• Result of the operations (success or failure)
• Total number of null operations
• Total number of compound operations
• Total number of access operations
• Total number of close operations
• Total number of commit operations
• Total number of create operations
• Total number of delegpurge operations
• Total number of delegret operations
• Total number of getattr operations
• Total number of getfh operations
• Total number of link operations
• Total number of lock operations
• Total number of lockt operations
• Total number of locku operations
• Total number of lookup operations
• Total number of lookupp operations
• Total number of nverify operations
• Total number of open operations
• Total number of openattr operations
• Total number of openconf operations
• Total number of opendowng operations
• Total number of putfh operations
• Total number of putpubfh operations
• Total number of putrootfh operations
• Total number of read operations
• Total number of readdir operations
• Total number of readlink operations
• Total number of remove operations
• Total number of rename operations
• Total number of renew operations
• Total number of restorefh operations
• Total number of savefh operations
• Total number of secinfo operations
• Total number of setattr operations
• Total number of setcliid operations
• Total number of setcliidconf operations
• Total number of verify operations
• Total number of write operations
• Total number of rellockown operations
• Total number of total operations
• Percent of null operations
• Percent of compound operations
• Percent of access operations
• Percent of close operations
• Percent of commit operations
• Percent of create operations
• Percent of delegpurge operations
• Percent of delegret operations
- Percent of getattr operations
- Percent of getfh operations
- Percent of link operations
- Percent of lock operations
- Percent of lockt operations
- Percent of locku operations
- Percent of lookup operations
- Percent of lookupp operations
- Percent of nverify operations
- Percent of open operations
- Percent of openattr operations
- Percent of openconf operations
- Percent of opendowng operations
- Percent of putfh operations
- Percent of putpubfh operations
- Percent of putrootfh operations
- Percent of read operations
- Percent of readdir operations
- Percent of readlink operations
- Percent of remove operations
- Percent of rename operations
- Percent of renew operations
- Percent of restorefh operations
- Percent of savefh operations
- Percent of secinfo operations
- Percent of setattr operations
- Percent of setcliid operations
- Percent of setCliidconf operations
- Percent of verify operations
- Percent of write operations
- Percent of relockown operations

This command is designed to be used to analyze performance characteristics and to help diagnose issues.
Parameters

{ [\[-fields\ <fieldname>, \ldots\]}

If you specify the `-fields <fieldname>, \ldots` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

\[ [-instance \]]\]

If you specify the `-instance` parameter, the command displays detailed information about all fields.

\[-node\ <nodename>|local\] - Node

If you specify this parameter, the command displays NFSv4 statistics only for the specified node.

\[-result\ success|failure|all\] - Result

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified result (success/failure/all).

\[-null\ <Counter with Delta>\] - Null Procedure

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of null operations.

\[-cmpnd\ <Counter with Delta>\] - Compound Procedure

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of compound operations.

\[-access\ <Counter with Delta>\] - Access Operations

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of access operations.

\[-close\ <Counter with Delta>\] - Close Operations

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of close operations.

\[-commit\ <Counter with Delta>\] - Commit Operations

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of commit operations.

\[-create\ <Counter with Delta>\] - Create Operations

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of create operations.

\[-delpur\ <Counter with Delta>\] - Delegpurge Operations

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of delegpurge operations.

\[-delrtn\ <Counter with Delta>\] - Delegret Operations

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of delegret operations.

\[-gattr\ <Counter with Delta>\] - GetAttr Operations

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of getattr operations.

\[-getfh\ <Counter with Delta>\] - GetFh Operations

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of getfh operations.

\[-link\ <Counter with Delta>\] - Link Operations

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of link operations.
[-lock <Counter with Delta>] - Lock Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of lock operations.

[-lockt <Counter with Delta>] - LockT Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of lockt operations.

[-locku <Counter with Delta>] - LockU Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of locku operations.

[-lookup <Counter with Delta>] - Lookup Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of lookup operations.

[-lookpp <Counter with Delta>] - LookupP Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of lookpp operations.

[-nverify <Counter with Delta>] - Nverify Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of nverify operations.

[-open <Counter with Delta>] - Open Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of open operations.

[-opattr <Counter with Delta>] - OpenAttr Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of opattr operations.

[-opconf <Counter with Delta>] - OpenConf Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of opconf operations.

[-opndg <Counter with Delta>] - OpenDowng Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of opndg operations.

[-putfh <Counter with Delta>] - PutFh Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of putfh operations.

[-putpfh <Counter with Delta>] - PutPubFh Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of putpfh operations.

[-putrfh <Counter with Delta>] - PutRootFh Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of putrfh operations.

[-read <Counter with Delta>] - Read Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of read operations.

[-readdr <Counter with Delta>] - ReadDir Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of readdr operations.
[-rlink <Counter with Delta>] - ReadLink Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of readlink operations.

[-remove <Counter with Delta>] - Remove Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of remove operations.

[-rename <Counter with Delta>] - Rename Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of rename operations.

[-renew <Counter with Delta>] - Renew Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of renew operations.

[-restfh <Counter with Delta>] - RestoreFh Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of restorefh operations.

[-savefh <Counter with Delta>] - SaveFh Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of savefh operations.

[-secinf <Counter with Delta>] - SecInfo Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of secinfo operations.

[-sattr <Counter with Delta>] - SetAttr Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of setattr operations.

[-sclid <Counter with Delta>] - SetCliId Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of setcliid operations.

[-scidc <Counter with Delta>] - SetCliIdConf Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of setcliidconf operations.

[-verify <Counter with Delta>] - Verify Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of verify operations.

[-write <Counter with Delta>] - Write Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of write operations.

[-relown <Counter with Delta>] - RelLockOwn Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of rellockown operations.

[-total <Counter64 with Delta>] - Total Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of total nfsv4 operations.

[-null-pct <Counter with Delta>] - Percent Null Procedure
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of null operations.
[-cmpnd-pct <Counter with Delta>] - Percent Compound Procedure
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of compound operations.

[-access-pct <Counter with Delta>] - Percent Access Operations
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of access operations.

[-close-pct <Counter with Delta>] - Percent Close Operations
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of close operations.

[-commit-pct <Counter with Delta>] - Percent Commit Operations
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of commit operations.

[-create-pct <Counter with Delta>] - Percent Create Operations
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of create operations.

[-delpur-pct <Counter with Delta>] - Percent Delegpurge Operations
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of delegpurge operations.

[-delrtn-pct <Counter with Delta>] - Percent Delegret Operations
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of delegret operations.

[-gattr-pct <Counter with Delta>] - Percent GetAttr Operations
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of getattr operations.

[-getfh-pct <Counter with Delta>] - Percent GetFh Operations
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of getfh operations.

[-link-pct <Counter with Delta>] - Percent Link Operations
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of link operations.

[-lock-pct <Counter with Delta>] - Percent Lock Operations
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of lock operations.

[-lockt-pct <Counter with Delta>] - Percent LockT Operations
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of lockt operations.

[-locku-pct <Counter with Delta>] - Percent LockU Operations
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of locku operations.

[-lookup-pct <Counter with Delta>] - Percent Lookup Operations
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of lookup operations.

[-lookpp-pct <Counter with Delta>] - Percent LookupP Operations
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of lookupp operations.
[-nverfy-pct <Counter with Delta>] - Percent Nverify Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of nverify operations.

[-open-pct <Counter with Delta>] - Percent Open Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of open operations.

[-opattr-pct <Counter with Delta>] - Percent OpenAttr Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of openattr operations.

[-opconf-pct <Counter with Delta>] - Percent OpenConf Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of openconf operations.

[-opndg-pct <Counter with Delta>] - Percent OpenDowng Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of opendowng operations.

[-putfh-pct <Counter with Delta>] - Percent PutFh Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of putfh operations.

[-putpfh-pct <Counter with Delta>] - Percent PutPubFh Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of putpubfh operations.

[-putrfh-pct <Counter with Delta>] - Percent PutRootFh Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of putrootfh operations.

[-read-pct <Counter with Delta>] - Percent Read Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of read operations.

[-readdr-pct <Counter with Delta>] - Percent ReadDir Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of readdir operations.

[-rlink-pct <Counter with Delta>] - Percent ReadLink Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of readdir operations.

[-remove-pct <Counter with Delta>] - Percent Remove Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of remove operations.

[-rename-pct <Counter with Delta>] - Percent Rename Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of rename operations.

[-renew-pct <Counter with Delta>] - Percent Renew Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of renew operations.

[-restfh-pct <Counter with Delta>] - Percent RestoreFh Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of restorefh operations.
[-savefh-pct <Counter with Delta>] - Percent SaveFh Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of savefh operations.

[-secinf-pct <Counter with Delta>] - Percent SecInfo Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of secinfo operations.

[-sattr-pct <Counter with Delta>] - Percent SetAttr Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of setattr operations.

[-sclid-pct <Counter with Delta>] - Percent SetCliId Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of setcliid operations.

[-scidc-pct <Counter with Delta>] - Percent SetCliIdConf Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of setcliidconf operations.

[-verify-pct <Counter with Delta>] - Percent Verify Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of verify operations.

[-write-pct <Counter with Delta>] - Percent Write Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of write operations.

[-relown-pct <Counter with Delta>] - Percent RelLockOwn Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of rellockown operations.

Examples
The following example displays statistics about the NFSv4 operations for a node named node1:

```
cluster1::> statistics-v1 nfs show-v4 -node node1
Node              Value       Delta     Percent Ops Delta
node1             ---------------------------success-----------------------
Null Procs:       2            -          1%          -
Cmpnd Procs:      92           -          32%         -
Access Ops:       16           -          6%          -
Close Ops:        8            -          3%          -
Commit Ops:       0            -          0%          -
Create Ops:       0            -          0%          -
Delpur Ops:       0            -          0%          -
Delrtn Ops:       0            -          0%          -
Getattr Ops:      76           -          27%         -
Getfh Ops:        22           -          8%          -
Link Ops:         0            -          0%          -
Lock Ops:         0            -          0%          -
Lockt Ops:        0            -          0%          -
Locku Ops:        0            -          0%          -
Lookup Ops:       13           -          5%          -
Lookupp Ops:      0            -          0%          -
Nverify Ops:      0            -          0%          -
Open Ops:         8            -          3%          -
Openattr Ops:     0            -          0%          -
Openconf Ops:     0            -          0%          -
Opendowng Ops:    0            -          0%          -
Putfh Ops:        92           -          32%         -
Putpubfh Ops:     0            -          0%          -
Putrootfh Ops:    2            -          1%          -
Read Ops:         0            -          0%          -
Readdir Ops:      2            -          1%          -

Statistics Commands

Display operational statistics

The statistics commands display performance statistics.

statistics show

Display performance data for a time interval

Availability: This command is available to cluster and Vserver administrators at the advanced privilege level.

Description

This command displays performance data for a period of time.

To display data for a period of time, collect a sample using the statistics start and statistics stop commands. The data that displays is calculated data based on the samples the cluster collects. To view the sample, specify the -sample-id parameter.

Parameters

{-fields <fieldname>, ...}

If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

{-tab}

If this parameter is specified, the command displays performance data in tabular format.

{-object <text> - Object

Selects the objects for which you want to display performance data. To view a list of valid object names, type statistics show -object ? or statistics catalog object show. To specify multiple objects, use `|` between each object.

Caution: You should limit the scope of this command to only a few objects at a time to avoid a potentially significant impact on the performance of the system.
[-instance <text>] - Instance
Selects the instances for which you want to display performance data. If you do not specify this parameter, the command displays statistics for all of the instances associated with the specified objects. To specify multiple instances, use "|" between each instance.

For example, if you want to display disk object statistics, you can use this parameter to specify the name of a specific disk whose statistics you want to view. If you do not specify this parameter, the command displays statistics for all disks in the system.

[-counter <text>] - Counter
Selects the counters for which you want to display performance data. To specify multiple counters, use "|" between each counter.

[-preset <text>] - Preset
If this parameter is specified, the command displays statistics for the specified preset.

[-node <nodename>|local] - Node
Selects the nodes for which you want to display performance data.

[-vserver <vserver name>] - Vserver
Selects the Vserver for which you want to display performance data.

[-value <text>] - Text Value
Selects the performance data that matches the specified counter value.

[-labels <text>,... ] - List of Labels
Selects the performance data that matches the specified label.

[-values <text>,... ] - List of Values
Displays only the statistics that have the specified values.

[-filter <text>] - Filter Data
Selects performance data for the instance that matches the specified filter criteria. For example, to display the instances that match a value of greater than 50 for the total_ops counter, specify -filter "total_ops>50".

[-sample-id <text>] - Sample Identifier
Displays performance data for the specified sample. You collect a sample by using the statistics start and statistics stop commands.

[-interval <integer>] - Interval
Specifies, in seconds, the interval between statistics updates. The default setting is 5 seconds.

[-iterations <integer>] - Iterations
Specifies the number of iterations the command runs before terminating. The default setting is 1. If the number is 0 (zero), the command continues to run until you interrupt it by pressing Ctrl-C.

[-sort-key <text>] - Counter Used For Sorting
If this parameter is specified, the command displays statistics sorted by the specified counter. Only one counter can be specified.

[-sort-order {ascending|descending}] - Sort Order
This parameter may be used in conjunction with the -sort-key parameter. This parameter changes the order in which statistics are sorted. Possible values are ascending and descending. The default setting is descending.

[-max <integer>] - Maximum Number of Instances
Specifies the maximum number of instances to display. The default setting is to display all of the instances.
Examples

The following example starts collecting statistics and displays statistics for the sample named smpl_1 for counters: avg_processor_busy and cpu_busy

```
cluster1::*> statistics start -object system -counter avg_processor_busy|cpu_busy -sample-id smpl_1
Statistics collection is being started for Sample-id: smpl_1

cluster1::*> statistics show -sample-id smpl_1
Object: system
Instance: cluster
Start-time: 8/2/2012 18:27:53
End-time: 8/2/2012 18:27:56
Cluster: cluster1
Counter                      Value
-------------------------------- --------------------------------
avg_processor_busy                                             6%
cpu_busy                                                       6%
```

The following example starts and stops data collection and displays statistics for the sample named smpl_1 for counters: avg_processor_busy and cpu_busy

```
cluster1::*> statistics start -object system -counter avg_processor_busy|cpu_busy -sample-id smpl_1
Statistics collection is being started for Sample-id: smpl_1

cluster1::*> statistics stop -sample-id smpl_1
Statistics collection is being stopped for Sample-id: smpl_1

cluster1::*> statistics show -sample-id smpl_1
Object: system
Instance: cluster
Start-time: 8/2/2012 18:27:53
End-time: 8/2/2012 18:27:56
Cluster: cluster1
Counter                      Value
-------------------------------- --------------------------------
avg_processor_busy                                             6%
cpu_busy                                                       6%
```

The following example displays raw statistics:

```
cluster1::*> statistics show -raw -object system

**statistics show-periodic**

Continuously display current performance data at regular interval

**Availability:** This command is available to `cluster` and `Vserver` administrators at the `advanced` privilege level.

**Description**

This command continuously displays specified performance data at a regular interval. The command output displays data in the following columns:

- **Note:** This command has been deprecated and may be removed from a future version of Data ONTAP. Use the "statistics show" command with the tabular format instead.

- cpu busy: Overall system utilization based on CPU utilization and subsystem utilization. Examples of subsystems include the storage subsystem and RAID subsystem.
- total ops: The number of total operations per second.
- nfs-ops: The number of NFS operations per second.
- cifs-ops: The number of CIFS operations per second.
- data busy: The percentage of time that data ports sent or received data.
- data recv: Network traffic received on data ports (KBps).
- data sent: Network traffic sent on data ports (KBps).
- cluster busy: The percentage of time that cluster ports sent or received data.
- cluster recv: Network traffic received on cluster ports (KBps).
- cluster sent: Network traffic sent on cluster ports (KBps).
- disk read: Data read from disk (KBps).
- disk write: Data written to disk (KBps).

**Parameters**

- `-object <text>` - Object

Selects the object for which you want to display performance data. The default object is "cluster".
[-instance <text>] - Instance
Selects the instance for which you want to display performance data. This parameter is required if you specify
the -object parameter and enter any object other than "cluster". Multiple values for this parameter are not supported.
For example, if you want to display disk object statistics, you can use this parameter to specify the name of a
specific disk whose statistics you want to view.

[-counter <text>] - Counter
Selects the counters for which you want to display performance data. If you do not specify this parameter, the
command displays statistics for all of the counters in the specified objects. To specify multiple counters, use
"|" between each counter.

[-preset <text>] - Preset
If this parameter is specified, the command displays statistics for the specified preset.

[-node {<nodename>|local}] - Node
Selects the nodes for which you want to display performance data. The default node is "cluster:summary".

[-vserver <vserver name>] - Vserver
Selects the Vserver for which you want to display performance data. If you do not specify this parameter, the
command displays statistics for all of the Vservers in the cluster.

[-interval <integer>] - Interval in Seconds
Specifies, in seconds, the interval between statistics updates. The default setting is 1 second.

[-iterations <integer>] - Number of Iterations
Specifies the number of iterations the command runs before terminating. The default setting is 0 (zero); this
means that the command continues to run until you interrupt it by pressing Ctrl-C.

[-summary {true|false}] - Print Summary
Specifies whether the command prints a final summary of statistics after the command has gone through all of
its iterations. The default setting is true.

[-filter <text>] - Filter Data
Selects instances that match the specified filter criteria. For example, to display instances from node1, specify
-filter "node_name=node1".

Examples
The following example displays the "cluster" statistics for a node named node1. Because no number of iterations is
specified, this command will continue to run until you interrupt it by pressing Ctrl-C.

```
cluster1::*> statistics show-periodic -node node1
```

statistics show-periodic
The following example displays the "processor" statistics for an instance named processor1. This command will display only five iterations.

```
cluster1::*> statistics show-periodic -object processor -instance processor1 -iteration 5
instance name     node processor name elapsed busy time switches
---------- ------- -------- ------- --------- -------- ---------- --------
processor0 processor0 -       2%         -     1022
processor0 processor0 -       1%         -      959
processor0 processor0 -       2%         -     1098
processor0 processor0 -       2%         -      870
processor0 processor0 -       2%         -     1107

[...]
```

The following example displays the processor statistics for an instance named processor1 and counters "processor_busy" and "sk_switches". This command will display only five iterations.

```
cluster1::*> statistics show-periodic -object processor -instance processor1 -iteration 5 -counter processor_busy|sk_switches
processor name     sk busy switches
---------- -------- --------
processor0 5% 1267
processor0 4% 1163
processor0 7% 1512
processor0 5% 1245
processor0 4% 1128

[...]
```

### statistics start

Start data collection for a sample

**Availability:** This command is available to `cluster` and `Vserver` administrators at the `advanced` privilege level.

**Description**

This command starts the collection of performance data. Use the `statistics stop` command to stop the collection. You view the sample of performance data by using the `statistics show` command. You can collect more than one sample at a time.

**Parameters**

[-object `<text>`] - Object

Selects the objects for which you want to collect performance data. This parameter is required. To view a list of valid object names, type `statistics catalog object show` at the command prompt. To specify multiple objects, use "|" between each object.

**Caution:** You should limit the scope of this command to only a few objects at a time to avoid a potentially significant impact on the performance of the system.

[-instance `<text>`] - Instance

Selects the instances for which you want to collect performance data. If you do not specify this parameter, the command collects statistics for all of the instances associated with the specified objects. To specify multiple instances, use "|" between each instance.
For example, if you want to collect disk object statistics, you can use this parameter to specify the name of a specific disk whose statistics you want to view. If you do not specify this parameter, the command will collect statistics for all disks in the system.

[-counter <text>] - Counter
Selects the counters for which you want to collect performance data. If you do not specify this parameter, the command collects statistics for all of the counters in the specified objects. To specify multiple counters, use "|" between each counter.

[-preset <text>] - Preset
If this parameter is specified, the command displays statistics for the specified preset.

[-sample-id <text>] - Sample Identifier
Specifies an identifier for the sample. Identifiers must be unique and are restricted to the characters 0-9, a-z, A-Z, and ".". If you do not specify this parameter, the command generates a sample identifier for you and defines this sample as the default sample for the CLI session. When you run the statistics show command without specifying the -sample-id parameter, data from the default sample displays. If you run this command during the same CLI session and do not specify the -sample-id parameter, the command overwrites the previous sample. The command does not delete the default sample when you close your session.

[-vserver <vserver name>] - Vserver
Selects the vserver for which you want to collect performance data. If you do not specify this parameter, the command collects statistics for all of the Vservers in the cluster.

[-node {<nodename> | local}] - Node
Selects the node for which you want to collect performance data. If you do not specify this parameter, the command collects statistics for all of the nodes in the cluster.

[-filter <text>] - Filter
Selects performance data for the instance that matches the specified filter criteria. For example, to display the instances from node1, specify -filter "node_name=node1".

[-duration <integer>] - Sample Duration in Minutes
If this parameter is specified, the command will collect the closing sample after the time specified. Duration can be specified in minutes.

[-max <integer>] - Maximum Number of Instances
Specifies the maximum number of instances to display. The default setting is to display all of the instances.

[-sort-key <text>] - Counter Used For Sorting
If this parameter is specified, the command displays statistics sorted by the specified counter. Only one counter can be specified.

[-sort-order {ascending|descending}] - Sort Order
This parameter may be used in conjunction with the -sort-key parameter. This parameter changes the order in which statistics are sorted. Possible values are ascending and descending. The default setting is descending.

Examples
The following example starts statistics collection for sample "smpl_1":

```
cluster1:*> statistics start -object system -sample-id smpl_1
Statistics collection is being started for Sample-id: smpl_1
```

The following example starts collecting statistics for the sample named smpl_1 for counters: avg_processor_busy and cpu_busy

statistics stop

Stop data collection for a sample

Availability: This command is available to cluster and Vserver administrators at the advanced privilege level.

Description

This command stops the collection of performance data. You view the sample of performance data by using the statistics show command.

Parameters

- `-sample-id <text>` - Sample Identifier

  Specifies the identifier of the sample for which you want to stop data collection. If you do not specify this parameter, the command stops data collection for the last sample that you started by running the statistics start command without the `-sample-id` parameter.

Examples

The following example stops data collection for sample "smpl_1":

```
cluster1::*> statistics stop -sample-id smpl_1
Statistics collection is being stopped for Sample-id: smpl_1
```

statistics aggregate commands

Aggregate throughput and latency metrics

statistics aggregate show

Aggregate throughput and latency metrics

Availability: This command is available to cluster administrators at the admin privilege level.

Description

This command continuously displays performance data for aggregates at a regular interval. The command output displays data in the following columns:
• Aggregate - aggregate name.
• Node - node name.
• Total Ops - total number of operations per second.
• Read Ops - read operations per second.
• Write Ops - write operations per second.

Parameters
[-aggregate <text>] - Aggregate

Selects the aggregate for which you want to display performance data.

[-node {<nodename>|local}] - Node

Selects the node for which you want to display performance data.

[-sort-key <text>] - Column to Sort By

If this parameter is specified, the command displays statistics sorted by the specified column.

-interval <integer> - Interval

Specifies, in seconds, the interval between statistics updates. The default setting is 5 seconds.

-iterations <integer> - Iterations

Specifies the number of iterations the command runs before terminating. The default setting is 1. If the number is 0 (zero), the command continues to run until you interrupt it by pressing Ctrl-C.

-max <integer> - Maximum Number of Instances

Specifies maximum number of aggregates to display. The default setting is 25.

Examples

The following example displays aggregate statistics:

```
cluster1::> statistics aggregate show
cluster-1 : 12/31/1969 16:00:04

*Total Read Write
Aggregate          Node    Ops  Ops   Ops
--------------------- ------------- ------ ---- -----
aggr0_cluster_node2_0 cluster-node2      9    0     8
aggr0 cluster-node1      6    0     5

[...]
```

统计缓存命令

显示缓存的性能数据

统计缓存闪存池命令

闪存池吞吐量指标

统计缓存闪存池显示

闪存池吞吐量指标

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.
Description
This command continuously displays performance data for flash pool caches at a regular interval. The command output displays data in the following columns:

- Aggregate - aggregate name.
- Vserver - vserver name.
- Volume - volume name.
- Read Hit - percent of IOs serviced from a cache level.
- Write Hit - percent of IOs serviced from a cache level.
- Cache Used - percent of cache used.
- Read Blocks - read blocks.
- Write Blocks - write blocks.
- Rejects - cache rejects.

Parameters

[-aggregate <text>] - Aggregate
Selects the aggregate for which you want to display performance data.

[-vserver <vserver name>] - Vserver
Selects the vserver for which you want to display performance data.

[-volume <text>] - Volume
Selects the volume for which you want to display performance data.

[-sort-key <text>] - Column to Sort By
If this parameter is specified, the command displays statistics sorted by the specified column.

-interval <integer> - Interval
Specifies, in seconds, the interval between statistics updates. The default setting is 5 seconds.

-iterations <integer> - Iterations
Specifies the number of iterations the command runs before terminating. The default setting is 1. If the number is 0 (zero), the command continues to run until you interrupt it by pressing Ctrl-C.

-max <integer> - Maximum Number of Instances
Specifies the maximum number of flash pools to display. The default setting is 25.

Examples
The following example displays flash pool statistics:

```
cluster1::> statistics cache flash-pool show
cluster1 : 12/31/2013 16:00:04

statistics catalog directory

Performance Catalog

The statistics catalog commands provide access to performance catalog data.

statistics catalog counter commands

The counter directory

statistics catalog counter show

Display the list of counters in an object

Availability: This command is available to cluster and Vserver administrators at the advanced privilege level.

Description
This command displays the names and descriptions of counters. The displayed data is either node-specific or cluster-wide, depending on the objects specified.

Parameters
{-fields <fieldname>, ...}
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

[-describe]
Displays detailed information about each counter, including privilege level, label, and whether the counter is a key counter.

-object <text> - Object
Selects the object for which you want to display the list of counters. This parameter is required. To view a list of valid object names, type statistics catalog counter show -object ? or statistics catalog object show.

[-counter <text>] - Counter
Selects the counters that match this parameter value. If you do not specify this parameter, the command displays details for all counters.

[-filter <text>] - Filter Data
Selects the counters that match this parameter value. For example, to display counters from node1, specify -filter "node_name=node1".

[-label <text>, ...] - Labels for Array Counters
Selects the counters that match this parameter value. A label is the name of the bucket to which an array counter belongs.

[-description <text>] - Description
Selects the counters that match this parameter value.

[-privilege <text>] - Privilege Level
Selects the counters that match this parameter value.

[-is-key-counter {true|false}] - Is Key Counter
Selects the counters that are key counters (true) or are not key counters (false). A key counter is a counter that uniquely identifies an instance across the cluster. The default setting is false. For example, "vserver_name" and
"node_name" are key counters because they identify the specific Vserver or node to which the instance belongs.

`[-is-deprecated (true|false)] - Is Counter Deprecated`
Selects the counters that are deprecated (true) or are not deprecated (false).

`[-replaced-by <text>] - Replaced By Counter If Deprecated`
Selects all deprecated counters that are replaced by the counter provided to this parameter.

### Examples
The following example displays the list of counters in the processor object.

```
cluster1::> statistics catalog counter show -object processor
```

<table>

### statistics catalog object commands
The object directory

#### statistics catalog object show
Display the list of objects

**Availability:** This command is available to cluster and Vserver administrators at the *advanced* privilege level.

**Description**
This command displays the names and descriptions of objects from which you can obtain performance data. The displayed data is either node-specific or cluster-wide, depending on the objects specified.

**Parameters**

```
[-fields <fieldname>, ...]
```
If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `'-fields ?'` to display the fields to specify.

```
[-describe]
```
Displays detailed information about each object, including privilege level.

```
[-object <text>] - Object
```
Selects the objects for which you want to display information. If you do not specify this parameter, the command displays details for all of the objects.

```
[-privilege <text>] - Privilege Level
```
Selects the objects that match this parameter value.
[-is-deprecated {true|false}] - Is Object Deprecated

Selects the objects that are deprecated (true) or are not deprecated (false).

[-replaced-by <text>] - Replaced By Object If Deprecated

Selects all deprecated objects that are replaced by the object provided to this parameter.

[-is-statistically-tracked {true|false}] - Is Object Statistically Tracked

Specifies if the object is statistically tracked

[-description <text>] - Description

Selects the objects that match this parameter value.

Examples

The following example displays descriptions of all objects in the cluster:

```
cluster1::> statistics catalog object show
aggregate                   CM object for exporting aggregate performance counters
audit_ng                    CM object for exporting audit_ng performance counters
cifs                        These counters report activity from both SMB and SMB2 revisions of the CIFS protocol. For information isolated to SMB, see the 'smb1' object. For SMB2, see the 'smb2' object.
cifs:node                   These counters report activity from both SMB and SMB2 revisions of the CIFS protocol. For information isolated to SMB, see the 'smb1' object. For SMB2, see the 'smb2' object.
cifs:vserver                These counters report activity from both SMB and SMB2 revisions of the CIFS protocol. For information isolated to SMB, see the 'smb1' object. For SMB2, see the 'smb2' object.
cluster_peer                The cluster peer object contains peer counters.
[...]
```

statistics catalog instance commands

The instance directory

statistics catalog instance show

Display the list of instances associated with an object

Availability: This command is available to cluster and Vserver administrators at the advanced privilege level.

Description

This command displays the names of instances associated with the specified object. The displayed data is either node-specific or cluster-wide, depending on the objects specified.

Parameters

[-fields <fieldname>, ...]  
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use `-fields ?' to display the fields to specify.

-object <text> - Object

Selects the object for which you want to display the list of instances. This parameter is required. To view a list of valid object names, type statistics catalog instance show -object ? or statistics catalog object show.
[-instance <text>] - Instance Name
Selects the instances that match this parameter value. If you do not specify this parameter, the command displays all the instances.

[-filter <text>] - Filter Data
Selects the instances that match this parameter value. For example, to display instances from vserver1, specify -filter "vserver_name=vserver1".

[-vserver <vserver name>, ...] - Vserver Name
Selects the instances that match this parameter value. If you do not specify this parameter, the command displays instances for all of the Vservers in the cluster.

[-node {<nodename> | local}, ...] - Node Name
Selects the instances that match this parameter value. If you do not specify this parameter, the command displays instances for all of the nodes in the cluster.

Examples
The following example displays the list of instances associated with the processor object.

```
cluster1::> statistics catalog instance show -object processor
Object: processor
    processor0
    processor0
    processor1
    processor1
4 entries were displayed.
```

statistics disk commands
Disk throughput and latency metrics

statistics disk show
Disk throughput and latency metrics

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
This command continuously displays performance data for disks at a regular interval. The command output displays data in the following columns:

- Disk - disk name.
- Node - node name.
- Busy (%) - percentage of time there was at least one outstanding request to the disk.
- Total Ops - total operations per second.
- Read Ops - read operations per second.
- Write Ops - write operations per second.
Parameters

[-disk <text>] - Disk
Selects the disk for which you want to display performance data.

[-node {<nodename>|local}] - Node
Selects the node for which you want to display performance data.

[-sort-key <text>] - Column to Sort By
If this parameter is specified, the command displays statistics sorted by the specified column.

-<interval <integer> - Interval
Specifies, in seconds, the interval between statistics updates. The default setting is 5 seconds.

-<iterations <integer> - Iterations
Specifies the number of iterations the command runs before terminating. The default setting is 1. If the number is 0 (zero), the command continues to run until you interrupt it by pressing Ctrl-C.

-<max <integer> - Maximum Number of Instances
Specifies the maximum number of disks to display. The default setting is 25.

Examples
The following example displays disk statistics:

```
cluster1::> statistics disk show
cluster1 : 12/31/1969 16:00:04

Busy *Total Read Write
Disk         Node  (%)    Ops  Ops   Ops
-------- -------- ---- ------ ---- -----
VMw-1.31    node2    0      2    2     0
VMw-1.30    node2    0      3    0     3
VMw-1.3     node1    0      0    0     0
VMw-1.29    node2    0      1    0     1
[...]
```

statistics lif commands
Logical network interface throughput and latency metrics

statistics lif show
Logical network interface throughput and latency metrics

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
This command continuously displays performance data for LIFs at a regular interval. The command output displays data in the following columns:

- LIF - logical interface name.
- Vserver - vserver name.
- Recv Packet - packets received per second.
- Recv Data (Bps) - bytes received per second.
- Recv Errors - receive errors per second.
- Sent Packet - packets sent per second.
- Sent Data (Bps) - bytes sent per second.
- Sent Errors - transfer errors per second.
- Current Port - current use port.

**Parameters**

[-lif <text>] - LIF
  Selects the LIF for which you want to display performance data.

[-vserver <vserver name>] - Vserver
  Selects the vserver for which you want to display performance data.

[-sort-key <text>] - Column to Sort By
  If this parameter is specified, the command displays statistics sorted by the specified column.

-iteration <integer> - Interval
  Specifies, in seconds, the interval between statistics updates. The default setting is 5 seconds.

-iterations <integer> - Iterations
  Specifies the number of iterations the command runs before terminating. The default setting is 1. If the number is 0 (zero), the command continues to run until you interrupt it by pressing Ctrl-C.

-max <integer> - Maximum Number of Instances
  Specifies the maximum number of LIFs to display. The default setting is 25.

**Examples**

The following example displays LIFs statistics:

```
cluster1::> statistics lif show
cluster1 : 12/31/1969 16:00:04

**statistics lun commands**

LUN throughput and latency metrics

**statistics lun show**

LUN throughput and latency metrics

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

**Description**

This command continuously displays performance data for LUNs at a regular interval. The command output displays data in the following columns:
• Lun - LUN name.
• Vserver - vserver name.
• Total Ops - total number of operations per second.
• Read Ops - read operations per second.
• Write Ops - write operations per second.
• Other Ops - other operations per second.
• Read (Bps) - read throughput in bytes per second.
• Write (Bps) - write throughput in bytes per second.
• Latency(ms) - average latency for an operation in milliseconds.

**Parameters**

[-lun <text>] - Lun
Selects the LUN for which you want to display performance data.

[-vserver <vserver name>] - Vserver
Selects the vserver for which you want to display performance data.

[-sort-key <text>] - Column to Sort By
If this parameter is specified, the command displays statistics sorted by the specified column.

-interval <integer> - Interval
Specifies, in seconds, the interval between statistics updates. The default setting is 5 seconds.

-iterations <integer> - Iterations
Specifies the number of iterations the command runs before terminating. The default setting is 1. If the number is 0 (zero), the command continues to run until you interrupt it by pressing Ctrl-C.

-max <integer> - Maximum Number of Instances
Specifies the maximum number of LUNs to display. The default setting is 25.

**Examples**
The following example displays LUN statistics:

```
cluster1:/> statistics lun show
cluster1 : 12/31/2013 16:00:04

*Total Read Write Other   Read Write Latency
Lun Vserver Ops Ops   Ops  (Bps) (Bps)    (ms)
---- ------- ------ ---- ----- ----- ------ ----- -------
lun1  vs1  58   13    15    29 310585  3014      39
lun0  vs2  56    0    11    45  8192 28826      47

[...]
```

**statistics nfs commands**

Monitor NFS statistics
**statistics nfs show-mount**

Display mount statistics

**Availability:** This command is available to cluster administrators at the advanced privilege level.

**Description**
The `statistics nfs show-mount` command displays the following statistics about the NFS mounts on each node in the cluster:

- Result of the operations (success or failure)
- Total number of null operations
- Total number of mount operations
- Total number of dump operations
- Total number of unmount operations
- Total number of export operations
- Total number of exportall operations
- Total number of pathconf operations
- Total number of all the above operations

This command is designed to be used to analyze performance characteristics and to help diagnose issues.

**Parameters**

`{ [-fields <fieldname>, ...]`

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

`} [-instance]`

If you specify the `-instance` parameter, the command displays detailed information about all fields.

`[-node {<nodename>|local}] - Node`

If you specify this parameter, the command displays statistics only for the specified node.

`[-result {success|failure|all}] - Result`

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified result (success/failure/all).

`[-null <Counter with Delta>] - Null Operations`

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of null operations.

`[-mount <Counter with Delta>] - Mount Operations`

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of mount operations.

`[-dump <Counter with Delta>] - Dump Operations`

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of dump operations.
[[-unmnt <Counter with Delta>] - UnMount Operations
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of unmount operations.

[[-unmntall <Counter with Delta>] - UnMountAll Operations
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of unmountall operations.

[[-export <Counter with Delta>] - Export Operations
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of export operations.

[[-exportall <Counter with Delta>] - ExportAll Operations
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of exportall operations.

[[-pathconf <Counter with Delta>] - PathConf Operations
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of pathconf operations.

[[-total <Counter64 with Delta>] - Total Operations
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of total operations.

Examples

The following example displays statistics about the NFS mounts for a node named node1:

```
cluster1::*> statistics nfs show-mount -node node1

Node                     Value         Delta
node1               ----------success-------
Null Ops:                    2       0/s:16s
Mount Ops:                   1       0/s:16s
Dump Ops:                   0             -
Unmount Ops:                 1       0/s:16s
Unmount All Ops:             0             -
Export Ops:                  0             -
ExportAll Ops:               0             -
PathConf Ops:                0             -
Total Ops:                   4       0/s:16s

Node                     Value         Delta
node1               ----------failure-------
Null Ops:                    0             -
Mount Ops:                   0             -
Dump Ops:                   0             -
Unmount Ops:                 0             -
Unmount All Ops:             0             -
Export Ops:                  0             -
ExportAll Ops:               0             -
PathConf Ops:                0             -
Total Ops:                   0             -
```

statistics nfs show-nlm

(DEPRECATED)-Display NLM statistics

Availability: This command is available to cluster administrators at the advanced privilege level.

Description

The `statistics nfs show-nlm` command displays the following statistics about the Network Lock Manager (NLM) on each node in the cluster:
• Result of the operations (success or failure)
• Total number of null operations
• Total number of test operations
• Total number of lock operations
• Total number of cancel operations
• Total number of unlock operations
• Total number of granted operations
• Total number of share operations
• Total number of unshare operations
• Total number of nmlock operations
• Total number of freeall operations
• Total number of all the above operations

This command is designed to be used to analyze performance characteristics and to help diagnose issues.

**Note:** This command requires an effective cluster version earlier than Data ONTAP 9.0. Data for nodes running Data ONTAP 9.0 or later is not collected, and will not be displayed. Use the `statistics show-object nlm` command instead.

**Parameters**

{[-fields <fieldname>, ...]
  
  If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

[-instance ]

  If you specify the `-instance` parameter, the command displays detailed information about all fields.

[-node {<nodename>|local}] - Node

  If you specify this parameter, the command displays statistics only for the specified node.

[-result {success|failure|all}] - Result

  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified result (success/failure/all).

[-null <Counter with Delta>] - Null Operations

  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of null operations.

[-test <Counter with Delta>] - Test Operations

  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of test operations.

[-lock <Counter with Delta>] - Lock Operations

  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of lock operations.

[-cancel <Counter with Delta>] - Cancel Operations

  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of cancel operations.
[-unlock <Counter with Delta>] - Unlock Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of unlock operations.

[-granted <Counter with Delta>] - Granted Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of granted operations.

[-share <Counter with Delta>] - Share Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of share operations.

[-unshare <Counter with Delta>] - Unshare Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of unshare operations.

[-nmlock <Counter with Delta>] - NmLock Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of nmlock operations.

[-freeall <Counter with Delta>] - FreeAll Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of freeall operations.

[-total <Counter64 with Delta>] - Total Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of total operations.

Examples
The following example displays statistics about the NLM for a node named node1:

```
cluster1::*> statistics nfs show-nlm -node node1

Node                 Value         Delta
node1             --------success-------
Null:                    0             -
Test:                    0             -
Lock:                    2       0/s:23s
Cancel:                  0             -
Unlock:                  1       0/s:23s
Granted:                 0             -
Share:                   0             -
Unshare:                 0             -
NmLock:                  0             -
FreeAll:                 0             -
Total:                   3       0/s:23s

Node                 Value         Delta
node1             --------failure-------
Null:                    0             -
Test:                    0             -
Lock:                    0             -
Cancel:                  0             -
Unlock:                  0             -
Granted:                 0             -
Share:                   0             -
Unshare:                 0             -
NmLock:                  0             -
FreeAll:                 0             -
Total:                   0             -
```

statistics nfs commands
statistics nfs show-statusmon

Display status monitor statistics

Availability: This command is available to cluster administrators at the advanced privilege level.

Description

The statistics nfs show-statusmon command displays the following statistics about the Status Monitor on each node in the cluster:

- Result of the operations (success or failure)
- Total number of null operations
- Total number of stat operations
- Total number of monitor operations
- Total number of unmonitor operations
- Total number of unmonitor all operations
- Total number of simucrash operations
- Total number of notify operations
- Total number of all the above operations

This command is designed to be used to analyze performance characteristics and to help diagnose issues.

Parameters

[-fields <fieldname>, ...]
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

[-instance]
If you specify the -instance parameter, the command displays detailed information about all fields.

[-node <nodename> | local] - Node
If you specify this parameter, the command displays statistics only for the specified node.

[-result {success | failure | all}]- Result
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified result (success/failure/all).

[-null <Counter with Delta>] - Null Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of null operations.

[-stat <Counter with Delta>] - Stat Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of stat operations.

[-monitor <Counter with Delta>] - Monitor Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of monitor operations.
[-unmonitor <Counter with Delta>] - Unmonitor Operations

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of unmonitor operations.

[-unmonall <Counter with Delta>] - Unmonitor All Operations

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of unmonitor all operations.

[-simucrash <Counter with Delta>] - SimuCrash Operations

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of simucrash operations.

[-notify <Counter with Delta>] - Notify Operations

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of notify operations.

[-total <Counter64 with Delta>] - Total Operations

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of total operations.

Examples

The following example displays statistics about the status monitor for a node named node1:

```
cluster1::*> statistics nfs show-statusmon -node node1

Node                   Value         Delta
node1               --------success-------
Null Ops:                  0             -
Stat Ops:                  0             -
Monitor Ops:               0             -
Unmonitor Ops:             0             -
Unmon All Ops:             0             -
SimuCrash Ops:             0             -
Notify Ops:                0             -
Total Ops:                 0             -

Node                   Value         Delta
node1               --------failure-------
Null Ops:                  0             -
Stat Ops:                  0             -
Monitor Ops:               0             -
Unmonitor Ops:             0             -
Unmon All Ops:             0             -
SimuCrash Ops:             0             -
Notify Ops:                0             -

statistics nfs show-v3

Display NFSv3 statistics

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The statistics nfs show-v3 command displays the following statistics about the NFSv3 operations on each node in the cluster:

- Result of the operations (success or failure)
- Total number of null operations
- Total number of getattr operations
• Total number of setattr operations
• Total number of lookup operations
• Total number of access operations
• Total number of readsymlink operations
• Total number of read operations
• Total number of write operations
• Total number of create operations
• Total number of mkdir operations
• Total number of symlink operations
• Total number of mknod operations
• Total number of remove operations
• Total number of rmdir operations
• Total number of rename operations
• Total number of link operations
• Total number of readdir operations
• Total number of readdirplus operations
• Total number of fsstat operations
• Total number of fsinfo operations
• Total number of pathconf operations
• Total number of commit operations
• Total number of nfsv3 operations
• Percent of null operations
• Percent of getattr operations
• Percent of setattr operations
• Percent of lookup operations
• Percent of access operations
• Percent of readsymlink operations
• Percent of read operations
• Percent of write operations
• Percent of create operations
• Percent of mkdir operations
• Percent of symlink operations
• Percent of mknod operations
• Percent of remove operations
• Percent of rmdir operations
• Percent of rename operations
• Percent of link operations
• Percent of readdir operations
• Percent of readdirplus operations
• Percent of fsstat operations
• Percent of fsinfo operations
• Percent of pathconf operations
• Percent of commit operations

This command is designed to be used to analyze performance characteristics and to help diagnose issues.

Parameters

[-fields <fieldname>, ...]
   If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

[-instance ]
   If you specify the -instance parameter, the command displays detailed information about all fields.

[-node {<nodename>|local}] - Node
   If you specify this parameter, the command displays NFSv3 statistics only for the specified node.

[-result {success|failure|all}] - Result
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified result (success/failure/all).

[-null <Counter with Delta>] - Null Operations
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of null operations.

[-gattr <Counter with Delta>] - GetAttr Operations
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of getattr operations.

[-sattr <Counter with Delta>] - SetAttr Operations
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of setattr operations.

[-lookup <Counter with Delta>] - LookUp Operations
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of lookup operations.

[-access <Counter with Delta>] - Access Operations
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of access operations.

[-rsym <Counter with Delta>] - ReadSymlink Operations
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of readsymlink operations.
[-read <Counter with Delta>] - Read Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of read operations.

[-write <Counter with Delta>] - Write Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of write operations.

[-create <Counter with Delta>] - Create Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of create operations.

[-mkdir <Counter with Delta>] - MkDir Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of mkdir operations.

[-symlink <Counter with Delta>] - SymLink Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of symlink operations.

[-mknod <Counter with Delta>] - MkNod Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of mknod operations.

[-remove <Counter with Delta>] - Remove Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of remove operations.

[-rmdir <Counter with Delta>] - RmDir Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of rmdir operations.

[-rename <Counter with Delta>] - Rename Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of rename operations.

[-link <Counter with Delta>] - Link Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of link operations.

[-readdir <Counter with Delta>] - ReadDir Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of readdir operations.

[-readdirplus <Counter with Delta>] - ReadDirPlus Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of readdirplus operations.

[-fsstat <Counter with Delta>] - FsStat Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of fsstat operations.

[-fsinfo <Counter with Delta>] - FsInfo Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of fsinfo operations.

[-pconf <Counter with Delta>] - PathConf Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of pathconf operations.
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of commit operations.

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of total NFSv3 operations.

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of null operations.

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of getattr operations.

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of setattr operations.

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of lookup operations.

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of access operations.

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of readsymlink operations.

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of read operations.

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of write operations.

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of create operations.

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of mkdir operations.

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of symlink operations.

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of mknod operations.

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of remove operations.
[-rmdir-pct <Counter with Delta>] - Percent Rmdir Ops
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of rmdir operations.

[-rename-pct <Counter with Delta>] - Percent Rename Ops
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of rename operations.

[-link-pct <Counter with Delta>] - Percent Link Ops
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of link operations.

[-rdir-pct <Counter with Delta>] - Percent ReadDir Ops
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of readdir operations.

[-rdirp-pct <Counter with Delta>] - Percent ReadDirPlus Ops
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of readdirplus operations.

[-fsstat-pct <Counter with Delta>] - Percent FsStat Ops
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of fsstat operations.

[-fsinfo-pct <Counter with Delta>] - Percent FsInfo Ops
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of fsinfo operations.

[-pconf-pct <Counter with Delta>] - Percent PathConf Ops
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of pathconf operations.

[-commit-pct <Counter with Delta>] - Percent Commit Ops
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of commit operations.

Examples
The following example displays statistics about the NFSv3 operations for a node named node1:

```
cluster1::> statistics nfs show-v3 -node node1
Node                Value             Delta           Percent Ops   Delta
node1            ---------------------------success-----------------------
Null Ops:                    4             -              7%             -
GetAttr Ops:                10             -             19%             -
SetAttr Ops:                 2             -              4%             -
Lookup Ops:                  2             -              4%             -
Access Ops:                 14             -             26%             -
ReadSymlink Ops:             0             -              0%             -
Read Ops:                    0             -              0%             -
Write Ops:                   0             -              0%             -
Create Ops:                  2             -              4%             -
MkDir Ops:                   1             -              2%             -
Symlink Ops:                 0             -              0%             -
MkNod Ops:                   0             -              0%             -
Remove Ops:                  1             -              2%             -
RmDir Ops:                   0             -              0%             -
Rename Ops:                  0             -              0%             -
Link Ops:                    0             -              0%             -
ReadDir Ops:                 2             -              4%             -
ReadDirPlus Ops:             10             -             19%             -
FsStat Ops:                  1             -              2%             -
FsInfo Ops:                  5             -              9%             -
PathConf Ops:                0             -              0%             -
```
## statistics nfs show-v4

Display NFSv4 statistics

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

The `statistics nfs show-v4` command displays the following statistics about the NFSv4 operations on each node in the cluster:

- Result of the operations (success or failure)
- Total number of null operations
- Total number of compound operations
- Total number of access operations
• Total number of close operations
• Total number of commit operations
• Total number of create operations
• Total number of delegpurge operations
• Total number of delegret operations
• Total number of getattr operations
• Total number of getfh operations
• Total number of link operations
• Total number of lock operations
• Total number of lockt operations
• Total number of locku operations
• Total number of lookup operations
• Total number of lookupp operations
• Total number of nverify operations
• Total number of open operations
• Total number of openattr operations
• Total number of openconf operations
• Total number of opendowng operations
• Total number of putfh operations
• Total number of putpubfh operations
• Total number of putrootfh operations
• Total number of read operations
• Total number of readdir operations
• Total number of readlink operations
• Total number of remove operations
• Total number of rename operations
• Total number of renew operations
• Total number of restorefh operations
• Total number of savefh operations
• Total number of secinfo operations
• Total number of setattr operations
• Total number of setcliid operations
• Total number of setcliidconf operations
• Total number of verify operations
• Total number of write operations
• Total number of rellockown operations
• Total number of total operations
• Percent of null operations
• Percent of compound operations
• Percent of access operations
• Percent of close operations
• Percent of commit operations
• Percent of create operations
• Percent of delegpurge operations
• Percent of delegret operations
• Percent of getattr operations
• Percent of getfh operations
• Percent of link operations
• Percent of lock operations
• Percent of lockt operations
• Percent of locku operations
• Percent of lookup operations
• Percent of lookupp operations
• Percent of nverify operations
• Percent of open operations
• Percent of openattr operations
• Percent of openconf operations
• Percent of opendowng operations
• Percent of putfh operations
• Percent of putpubfh operations
• Percent of putrootfh operations
• Percent of read operations
• Percent of readdir operations
• Percent of readlink operations
• Percent of remove operations
• Percent of rename operations
• Percent of renew operations
• Percent of restorefh operations
• Percent of savefh operations
• Percent of secinfo operations
• Percent of setattr operations
• Percent of setcliid operations
• Percent of setClidconf operations
• Percent of verify operations
• Percent of write operations
• Percent of rellockown operations

This command is designed to be used to analyze performance characteristics and to help diagnose issues.

Parameters

[-fields <fieldname>, ...]
   If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use ‘-fields ?’ to display the fields to specify.

[-instance]]
   If you specify the -instance parameter, the command displays detailed information about all fields.

[-node {<nodename>|local}] - Node
   If you specify this parameter, the command displays NFSv4 statistics only for the specified node.

[-result {success|failure|all}] - Result
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified result (success/failure/all).

[-null <Counter with Delta>] - Null Procedure
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of null operations.

[-cmpnd <Counter with Delta>] - Compound Procedure
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of compound operations.

[-access <Counter with Delta>] - Access Operations
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of access operations.

[-close <Counter with Delta>] - Close Operations
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of close operations.

[-commit <Counter with Delta>] - Commit Operations
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of commit operations.

[-create <Counter with Delta>] - Create Operations
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of create operations.

[-delpur <Counter with Delta>] - Delegpurge Operations
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of delegpurge operations.
[-delrtn <Counter with Delta>] - Delegret Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of delegret operations.

[-gattr <Counter with Delta>] - GAttr Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of getattr operations.

[-getfh <Counter with Delta>] - GetFh Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of getfh operations.

[-link <Counter with Delta>] - Link Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of link operations.

[-lock <Counter with Delta>] - Lock Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of lock operations.

[-lockt <Counter with Delta>] - LockT Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of lockt operations.

[-locku <Counter with Delta>] - LockU Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of locku operations.

[-lookup <Counter with Delta>] - Lookup Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of lookup operations.

[-lookpp <Counter with Delta>] - LookupP Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of lookpp operations.

[-nverfy <Counter with Delta>] - Nverify Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of nverify operations.

[-open <Counter with Delta>] - Open Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of open operations.

[-opattr <Counter with Delta>] - OpenAttr Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of openattr operations.

[-opconf <Counter with Delta>] - OpenConf Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of openconf operations.

[-opndg <Counter with Delta>] - OpenDowng Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of opendowng operations.

[-putfh <Counter with Delta>] - PutFh Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of putfh operations.
[-putpfh <Counter with Delta>] - PutPubFh Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the
  specified number of putpubfh operations.

[-putrfh <Counter with Delta>] - PutRootFh Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the
  specified number of putrootfh operations.

[-read <Counter with Delta>] - Read Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the
  specified number of read operations.

[-readdr <Counter with Delta>] - ReadDir Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the
  specified number of readdir operations.

[-rlink <Counter with Delta>] - ReadLink Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the
  specified number of readlink operations.

[-remove <Counter with Delta>] - Remove Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the
  specified number of remove operations.

[-rename <Counter with Delta>] - Rename Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the
  specified number of rename operations.

[-renew <Counter with Delta>] - Renew Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the
  specified number of renew operations.

[-restfh <Counter with Delta>] - RestoreFh Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the
  specified number of restorefh operations.

[-savefh <Counter with Delta>] - SaveFh Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the
  specified number of savefh operations.

[-secinf <Counter with Delta>] - SecInfo Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the
  specified number of secinfo operations.

[-sattr <Counter with Delta>] - SetAttr Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the
  specified number of setattr operations.

[-sclid <Counter with Delta>] - SetCliId Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the
  specified number of setcliid operations.

[-scidc <Counter with Delta>] - SetCliIdConf Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the
  specified number of setcliidconf operations.

[-verify <Counter with Delta>] - Verify Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the
  specified number of verify operations.
[-write <Counter with Delta>] - Write Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of write operations.

[-relown <Counter with Delta>] - RelLockOwn Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of rellockown operations.

[-total <Counter64 with Delta>] - Total Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of total nfv4 operations.

[-null-pct <Counter with Delta>] - Percent Null Procedure
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of null operations.

[-cmpnd-pct <Counter with Delta>] - Percent Compound Procedure
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of compound operations.

[-access-pct <Counter with Delta>] - Percent Access Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of access operations.

[-close-pct <Counter with Delta>] - Percent Close Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of close operations.

[-commit-pct <Counter with Delta>] - Percent Commit Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of commit operations.

[-create-pct <Counter with Delta>] - Percent Create Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of create operations.

[-delpur-pct <Counter with Delta>] - Percent Delegpurge Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of delegpurge operations.

[-delrtn-pct <Counter with Delta>] - Percent Delegret Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of delegret operations.

[-gattr-pct <Counter with Delta>] - Percent GetAttr Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of getattr operations.

[-getfh-pct <Counter with Delta>] - Percent GetFh Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of getfh operations.

[-link-pct <Counter with Delta>] - Percent Link Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of link operations.

[-lock-pct <Counter with Delta>] - Percent Lock Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of lock operations.
[-lockt-pct <Counter with Delta>] - Percent LockT Operations

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of lockt operations.

[-locku-pct <Counter with Delta>] - Percent LockU Operations

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of locku operations.

[-lookup-pct <Counter with Delta>] - Percent Lookup Operations

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of lookup operations.

[-lookpp-pct <Counter with Delta>] - Percent LookupP Operations

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of lookpp operations.

[-nverify-pct <Counter with Delta>] - Percent Nverify Operations

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of nverify operations.

[-open-pct <Counter with Delta>] - Percent Open Operations

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of open operations.

[-opattr-pct <Counter with Delta>] - Percent OpenAttr Operations

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of openattr operations.

[-opconf-pct <Counter with Delta>] - Percent OpenConf Operations

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of openconf operations.

[-opndg-pct <Counter with Delta>] - Percent OpenDowng Operations

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of opendowng operations.

[-putfh-pct <Counter with Delta>] - Percent PutFh Operations

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of putfh operations.

[-putpfh-pct <Counter with Delta>] - Percent PutPubFh Operations

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of putpubfh operations.

[-putrfh-pct <Counter with Delta>] - Percent PutRootFh Operations

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of putrootfh operations.

[-read-pct <Counter with Delta>] - Percent Read Operations

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of read operations.

[-readdr-pct <Counter with Delta>] - Percent ReadDir Operations

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of readdir operations.

[-rlink-pct <Counter with Delta>] - Percent ReadLink Operations

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of readlink operations.
[-remove-pct <Counter with Delta>] - Percent Remove Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of remove operations.

[-rename-pct <Counter with Delta>] - Percent Rename Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of rename operations.

[-renew-pct <Counter with Delta>] - Percent Renew Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of renew operations.

[-restfh-pct <Counter with Delta>] - Percent RestoreFh Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of restorefh operations.

[-savefh-pct <Counter with Delta>] - Percent SaveFh Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of savefh operations.

[-secinf-pct <Counter with Delta>] - Percent SecInfo Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of secinfo operations.

[-sattr-pct <Counter with Delta>] - Percent SetAttr Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of setattr operations.

[-sclid-pct <Counter with Delta>] - Percent SetCliId Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of setcliid operations.

[-scidc-pct <Counter with Delta>] - Percent SetCliIdConf Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of setcliidconf operations.

[-verify-pct <Counter with Delta>] - Percent Verify Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of verify operations.

[-write-pct <Counter with Delta>] - Percent Write Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of write operations.

[-relown-pct <Counter with Delta>] - Percent RelLockOwn Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of rellockown operations.

Examples
The following example displays statistics about the NFSv4 operations for a node named node1:

```sh
cluster1::> statistics nfs show-v4 -node node1
```

<table>

statistics node commands

System utilization metrics for each node in the cluster

statistics node show

System utilization metrics for each node in the cluster

Availability: This command is available to cluster administrators at the admin privilege level.

Description
This command continuously displays performance data for nodes at a regular interval. The command output displays data in the following columns:

- Node - node name.
- CPU (%) - CPU utilization.
- Total Ops - total number of operations per second.
- Latency(ms) - average latency for an operation in milliseconds.

Parameters

[-node <nodename> | local] - Node

Selects the node for which you want to display performance data.
[-sort-key <text>] - Column to Sort By
   If this parameter is specified, the command displays statistics sorted by the specified column.

-interval <integer> - Interval
   Specifies, in seconds, the interval between statistics updates. The default setting is 5 seconds.

-iterations <integer> - Iterations
   Specifies the number of iterations the command runs before terminating. The default setting is 1. If the number
   is 0 (zero), the command continues to run until you interrupt it by pressing Ctrl-C.

-max <integer> - Maximum Number of Instances
   Specifies the maximum number of aggregates to display. The default setting is 25.

Examples
The following example displays node statistics:

```
cluster1::> statistics node show
cluster1 : 12/31/2013 16:00:04

   CPU *Total Latency
       Node (%)    Ops    (ms)
           ----- --- ------ -------
   node2  76    113       -
   node1  58     10       -
   [...]
```

statistics oncrpc commands
Monitor ONC RPC statistics

statistics oncrpc show-rpc-calls
Display ONC RPC Call Statistics

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
Attention: This command is deprecated and will be removed in a future major release.

The statistics oncrpc show-rpc-calls command displays information about the Open Network Computing Remote Procedure Call (ONC RPC) calls performed by the nodes of a cluster.

Parameters

[-fields <fieldname>,...]
   If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified
   field or fields. You can use ‘-fields ?’ to display the fields to specify.

[-instance]
   If you specify the -instance parameter, the command displays detailed information about all fields.

[-node {<nodename>|local}] - Node
   Use this parameter to display information only about the RPC calls performed by the node you specify.
[-protocol \(TCP\|UDP\)] - Transport Protocol

Use this parameter to display information only about the RPC calls performed using the network protocol you specify.

[-badproc <Counter with Delta>] - Bad Procedure Calls

Use this parameter to display information only about the RPC calls that have the number of bad procedure calls you specify. Bad procedure calls are RPC requests that contain invalid procedure numbers and cannot be completed.

[-badlen <Counter with Delta>] - Bad Length Calls

Use this parameter to display information only about the RPC calls that have the number of bad length calls you specify.

[-badhdr <Counter with Delta>] - Bad Header Calls

Use this parameter to display information only about the RPC calls that have the number of bad header calls you specify.

[-badcalls <Counter with Delta>] - Bad Calls

Use this parameter to display information only about the RPC calls that have the number of bad calls you specify.

[-badprogcalls <Counter with Delta>] - Bad Program Calls

Use this parameter to display information only about the RPC calls that have the number of bad program calls you specify.

[-calls <Counter64 with Delta>] - Total Calls

Use this parameter to display information only about the RPC calls that have the total number of bad calls you specify.

Examples

```
cluster1::> statistics oncrpc show-rpc-calls

Node               Value              Delta
node1           ------------tcp-------------

statistics port commands
Displays performance data for ports

statistics port fcp commands
FCP port interface throughput and latency metrics

statistics port fcp show
FCP port interface throughput and latency metrics
Availability: This command is available to cluster administrators at the admin privilege level.

Description
This command continuously displays performance data for FCP ports at a regular interval. The command output displays data in the following columns:

- Port - port name.
- Read Ops - read operations per second.
- Write Ops - write operations per second.
- Other Ops - other operations per second.

Parameters

- `-port <text>` - Port
  Selects the port for which you want to display performance data.

- `-sort-key <text>` - Column to Sort By
  If this parameter is specified, the command displays statistics sorted by the specified column.

- `-interval <integer>` - Interval
  Specifies, in seconds, the interval between statistics updates. The default setting is 5 seconds.

- `-iterations <integer>` - Iterations
  Specifies the number of iterations the command runs before terminating. The default setting is 1. If the number is 0 (zero), the command continues to run until you interrupt it by pressing Ctrl-C.

- `-max <integer>` - Maximum Number of Instances
  Specifies the maximum number of ports to display. The default setting is 25.

Examples
The following example displays port statistics:

```
cluster1::> statistics port fcp show
cluster1 : 12/31/2013 16:00:04

*Total Read Write
   Port     Ops  Ops   Ops
   ----- ------ ---- ----
```
Performance Preset configuration directory

Performance Preset directory

Directory contains commands to delete, modify, import, and display Performance Preset configurations and their details. A Performance Preset declares a list of one or more Performance Object names and a list of Performance Counter names (for each Object). Preset configurations expected to be used by the Performance Archive will specify sample periods for each Counter, declaring how often each Counter is to be archived. To create a new Performance Preset configuration, the `perf-preset-create` API or `statistics preset import` command must be used.

statistics preset delete

Delete an existing Performance Preset

**Availability**: This command is available to *cluster* administrators at the *advanced* privilege level.

**Description**

Deletes a performance preset configuration and all of its associated details.

**Parameters**

`-preset <text>` - *Preset Name*

Specifies the name of the performance presets that you want to delete.

**Examples**

```
cluster1:*> statistics preset show
  Preset Name: asup-event
  Preset UUID: 55c03699-01db-11e2-8e3e-123478563412

statistics preset import

Import Performance Preset configuration from source URI

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
Imports a Performance Preset and all of its details from a source URI. The performance preset will be created right after it is imported.

Parameters
- **source-uri** {ftp|http://(hostname|IPv4 Address|'[IPv6 Address'])...} - Source URI pointing to a preset file
  Specifies the URI from which to import a Performance Preset.

- **uri-username** <text> - Source URI username
  Specifies the URI username if needed.

- **uri-password** <text> - Source URI password
  Specifies the URI password if needed.

- **preset** <text> - Preset name
  Preset Name

- **comment** <text> - Preset Description
  Specifies the comment of the Performance Preset that you want to import.

- **privilege** <PrivilegeLevel> - Preset Privilege Level
  Specifies the privilege level that this preset can be created at. Possible values: admin, advanced, diagnostic.

- **is-archive-enabled** {true|false} - Is Preset Archive-Enabled?
  Specifies whether or not the Performance Preset will be archived. The preset will be archived if this option is set to true.

- **expiration-length** <integer> - Default Expiration Length (Minutes)
  Specifies the duration of time until this preset expires in minutes.

Examples

```console
cluster1::*> statistics preset show
 Preset Name: asup-event
 Preset UUID: 55c03699-01db-11e2-8e3e-123478563412

### statistics preset modify

Modify an existing Performance Preset

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

**Description**
Modifies an existing Performance Preset configuration. The command modifies the global properties of a Preset, but does not modify the details of the Preset, such as specific the objects and counters sampled.

**Parameters**

- **-preset <text>** - Preset Name  
  Name of the Performance Preset to be modified.

- **[-new-name <text>]** - New Preset Name  
  New Preset Name

- **[-comment <text>]** - Preset Description  
  Set comment to the given value.

- **[-privilege <PrivilegeLevel>]** - Preset Privilege Level  
  Set privilege level at which this Preset can be viewed and/or modified to the given value. Possible values: admin, advanced, diagnostic.

**Examples**

```
cluster1::*> statistics preset show  
Preset Name: delta  
Preset UUID: 7a04f19d-02a7-11e2-8e40-123478563412

### statistics preset show

Display information about Performance Presets

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

**Description**
Displays information about performance preset configurations.
Parameters
{ [-fields <fieldname>,...]
   Selects which performance preset attributes to display.

[ [-instance ]
   Shows details of all attributes of performance preset configuration.

[ [-preset <text>] - Preset Name
   Selects the performance presets that match the specified preset name.

[ [-comment <text>] - Preset Description
   Selects the performance presets that match the specified comment.

[ [-privilege <PrivilegeLevel> ] - Preset Privilege Level
   Selects the performance presets that are available with the specified privilege.

[ [-is-read-only {true|false}] - Is Preset Read-Only?
   Selects the performance presets that are read-only (true) or are not read-only (false). Read-only presets cannot be modified.

[ [-store <text>] - Name of Store Where Data is Saved
   Selects the store where data is saved.

<table>

Performance Preset Detail directory

Directory contains commands to display Performance Preset Details for Performance Preset configurations.

statistics preset detail show

Display information about Performance Preset Details

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
Displays the specific details of each preset, including the objects sampled, the counter sample periods, and the counters sampled.
Parameters

{-fields <fieldname>,...}
Selects which performance preset detail attributes to display.

{-instance}
Displays all of the performance preset detail attributes.

{-preset <text>} - Preset Name
Selects the performance preset details that match the specified preset name.

{-object <text>} - Performance Object
Selects the performance preset details that match the specified object name.

{-sample-period <sample_period>} - Archive Sample period
Selects the performance preset details that are collected at the specified sample period.

{-counter-set <text>,...} - Performance Counter Name Set
Selects the performance preset details that match the specified counters in the counter set. Use "|" to separate multiple counters.

{-instance-filters <text>,...} - Performance Instance Filters
Selects the performance preset details that match the specified instance filters. Use "|" to separate multiple instance filters. This field is reserved for future use.

Examples

```
cluster1:*> statistics preset detail show

statistics samples directory

Manage the statistics samples

The statistics samples commands provide information about samples.
statistics samples delete

Delete statistics samples

Availability: This command is available to cluster and Vserver administrators at the advanced privilege level.

Description
This command deletes samples that you created using the statistics start command.

Parameters
-vserver <vserver name> - Vserver
Selects the Vserver for which you want to delete the sample. The default Vserver is admin Vserver.

-sample-id <text> - Sample Identifier
Specifies the sample that you want to delete. This is a required parameter.

Examples
The following example deletes the sample "smpl_1":

cluster1:*> statistics samples delete -sample-id smpl_1

statistics samples show

Display statistics samples

Availability: This command is available to cluster and Vserver administrators at the advanced privilege level.

Description
This command displays information about the samples that you created using the statistics start command.

Parameters
[-fields <fieldname>, ...]
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

[[-describe]]
Displays detailed information about each sample.

-vserver <vserver name> - Vserver
Selects the samples that match this parameter value. If you omit this parameter, the command displays details for all samples.

-sample-id <text> - Sample Identifier
Selects the samples that match this parameter value. If you do not specify this parameter, the command will display information about all the samples in the cluster.

Examples
The following example displays information for sample "smpl_1":

The following example displays detailed information for sample "smpl_1":

cluster1::*> statistics samples show -sample-id smpl_1 -describe

  Vserver: vs1
  Sample ID: smpl_1
    Object: processor

**statistics settings commands**

Manage the displaying of statistics

**statistics settings modify**

Modify settings for the statistics commands

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

**Description**
This command modifies the settings for all of the *statistics* commands.

**Parameters**

[-display-rates {true|false}]- Display Rates
  Specifies whether the *statistics* commands display rate counters in rates/second. The default is true.

[-client-stats {enabled|disabled}]- Collect Per-Client Statistics
  Specifies whether *statistics* commands display per-client information. The default is disabled.

  **Note:** If you enable this setting, you might significantly impact system performance.

[-counter-display-units {B|KB|MB|GB}]- Counter Display Units
  Specifies display units for the counters. The default setting is MB.

[-display-count-exponent <integer>]- Display Count Exponent
  Specifies display exponent value for the counters representing counts. The default setting is 3 (thousand).

**Examples**

The following example sets the value of the -display-rates parameter to false:

**statistics system commands**

System utilization metrics for the cluster

**statistics system show**

System utilization metrics for the cluster

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**

This command continuously displays performance data for cluster at a regular interval. The command output displays data in the following columns:

- System - cluster name.
- CPU (%) - CPU utilization.
- Total Ops - total number of operations per second.
- Latency(ms) - average latency for an operation in milliseconds.

**Parameters**

[-system <text>] - System

Selects the cluster for which you want to display performance data.
[\-sort-key <text>] - Column to Sort By

If this parameter is specified, the command displays statistics sorted by the specified column.

\-interval <integer> - Interval

Specifies, in seconds, the interval between statistics updates. The default setting is 5 seconds.

\-iterations <integer> - Iterations

Specifies the number of iterations the command runs before terminating. The default setting is 1. If the number is 0 (zero), the command continues to run until you interrupt it by pressing Ctrl-C.

\-max <integer> - Maximum Number of Instances

Specifies the maximum number of systems to display. The default setting is 25.

Examples

The following example displays system statistics:

```
cluster1::> statistics system show
cluster1 : 12/31/2013 16:00:04

   CPU *Total Latency
    System (%)   Ops   (ms)
               ------- ------ -------
        Cluster  76  113     -
        ...
```

statistics top commands

Displays performance data for statistically tracked objects

statistics top client commands

Most active clients

statistics top client show

Most active clients

Availability: This command is available to cluster administrators at the advanced privilege level.

Description

This command continuously displays performance data for top clients at a regular interval. The command output displays data in the following columns:

- Client - client name.
- Vserver - vserver name.
- Node - node name.
- Protocol - protocol name.
- Total Ops - total number of operations per second.
- Total (Bps) - total throughput in bytes per second.
Parameters

[-node \(<\text{nodename}>|local\)] - Node

Selects the node for which you want to display performance data.

[-sort-key \(<\text{text}>\)] - Column to Sort By

If this parameter is specified, the command displays statistics sorted by the specified column.

-\( \text{interval} \ <\text{integer}> \) - Interval

Specifies, in seconds, the interval between statistics updates. The default setting is 5 seconds.

-\( \text{iterations} \ <\text{integer}> \) - Iterations

Specifies the number of iterations the command runs before terminating. The default setting is 1. If the number is 0 (zero), the command continues to run until you interrupt it by pressing Ctrl-C.

-\( \text{max} \ <\text{integer}> \) - Maximum Number of Instances

Specifies maximum number of top clients to display. The default setting is 10.

Examples

The following example displays top client statistics:

```
cluster1::> statistics top client show
cluster-1 : 12/31/1969 16:00:04

*Total Total
Client   Vserver          Node    Ops (Bps)
------------------ --------- ------------- ------ ----
172.17.236.53:938 vserver01 cluster-node2      9    80
172.17.236.160:898 vserver02 cluster-node1      6    50
[...]
```

**statistics top file commands**

Most actively accessed files

**statistics top file show**

Most actively accessed files

**Availability:** This command is available to cluster administrators at the advanced privilege level.

**Description**

This command continuously displays performance data for top files at a regular interval. The command output displays data in the following columns:

- File - file name.
- Volume - volume name.
- Vserver - vserver name.
- Aggregate - aggregate name.
- Node - node name.
- Total Ops - total number of operations per second.
- Total (Bps) - total throughput in bytes per second.
Parameters

[-node {<nodename> | local}] - Node

Selects the node for which you want to display performance data.

[-sort-key <text>] - Column to Sort By

If this parameter is specified, the command displays statistics sorted by the specified column.

- interval <integer> - Interval

Specifies, in seconds, the interval between statistics updates. The default setting is 5 seconds.

- iterations <integer> - Iterations

Specifies the number of iterations the command runs before terminating. The default setting is 1. If the number
is 0 (zero), the command continues to run until you interrupt it by pressing Ctrl-C.

- max <integer> - Maximum Number of Instances

Specifies maximum number of top files to display. The default setting is 10.

Examples

The following example displays top files statistics:

    cluster1::> statistics top file show
    cluster-1 : 12/31/1969 16:00:04

<table>
<thead>
<tr>

statistics volume commands

Volume throughput and latency metrics

statistics volume show

Volume throughput and latency metrics

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description

This command continuously displays performance data for volumes at a regular interval. The command output displays data in
the following columns:

- Volume - volume name.
- Vserver - vserver name.
- Aggregate - aggregate name.
- Total Ops - total number of operations per second.
- Read Ops - read operations per second.
- Write Ops - write operations per second.
- Other Ops - other operations per second.
- Read (Bps) - read throughput in bytes per second.
- Write (Bps) - write throughput in bytes per second.
- Latency(us) - average latency for an operation in microseconds.

Parameters

[-volume <text>] - Volume
Selects the volume for which you want to display performance data.

[-vserver <vserver name>] - Vserver
Selects the vserver for which you want to display performance data.

[-aggregate <text>] - Aggregate
Selects the aggregate for which you want to display performance data.

[-sort-key <text>] - Column to Sort By
If this parameter is specified, the command displays statistics sorted by the specified column.

-interval <integer> - Interval
Specifies, in seconds, the interval between statistics updates. The default setting is 5 seconds.

-iterations <integer> - Iterations
Specifies the number of iterations the command runs before terminating. The default setting is 1. If the number is 0 (zero), the command continues to run until you interrupt it by pressing Ctrl-C.

-max <integer> - Maximum Number of Instances
Specifies the maximum number of volumes to display. The default setting is 25.

Examples
The following example displays volume statistics:

```
cluster1::> statistics volume show
cluster1 : 12/31/2013 16:00:04

*Total Read Write Other   Read Write Latency
Volume Vserver Aggregate    Ops  Ops   Ops   Ops  (Bps) (Bps)    (us)

vol0   -     aggr0     58   13    15    29 310585  3014      39
vol0   -  aggr0_n0     56    0    11    45   8192 28826      47
```

statistics vserver commands
Vserver throughput and latency metrics

statistics vserver show
Vserver throughput and latency metrics

Availability: This command is available to cluster administrators at the admin privilege level.

Description
This command continuously displays performance data for Vservers at a regular interval. The command output displays data in the following columns:
- Vserver - Vserver name.
- Total Ops - total number of operations per second.
- Read Ops - read operations per second.
- Write Ops - write operations per second.
- Other Ops - other operations per second.
- Read (Bps) - read throughput in bytes per second.
- Write (Bps) - write throughput in bytes per second.
- Latency(us) - average latency for an operation in microseconds.

Parameters

[-vserver <vserver name>] - Vserver
Selects the vserver for which you want to display performance data.

[-sort-key <text>] - Column to Sort By
If this parameter is specified, the command displays statistics sorted by the specified column.

-interval <integer> - Interval
Specifies, in seconds, the interval between statistics updates. The default setting is 5 seconds.

-iterations <integer> - Iterations
Specifies the number of iterations the command runs before terminating. The default setting is 1. If the number
is 0 (zero), the command continues to run until you interrupt it by pressing Ctrl-C.

-max <integer> - Maximum Number of Instances
Specifies the maximum number of Vservers to display. The default setting is 25.

Examples

The following example displays Vserver statistics:

```
cluster1::> statistics vserver show
```
```
cluster1 : 12/31/2013 16:00:04

<table>
<thead>

statistics workload commands

QoS workload throughput and latency metrics

statistics workload show

QoS workload throughput and latency metrics

Availability: This command is available to cluster administrators at the advanced privilege level.
**Description**
This command continuously displays performance data for workloads at a regular interval. The command output displays data in the following columns:

- Workload - workload name.
- Total Ops - total number of operations per second.
- Read Ops - read operations per second.
- Write Ops - write operations per second.
- Other Ops - other operations per second.
- Read (Bps) - read throughput in bytes per second.
- Write (Bps) - write throughput in bytes per second.
- Latency(us) - average latency for an operation in microseconds.

**Parameters**

- `-workload <text>` - Workload
  Selects the workload for which you want to display performance data.

- `-sort-key <text>` - Column to Sort By
  If this parameter is specified, the command displays statistics sorted by the specified column.

- `-interval <integer>` - Interval
  Specifies, in seconds, the interval between statistics updates. The default setting is 5 seconds.

- `-iterations <integer>` - Iterations
  Specifies the number of iterations the command runs before terminating. The default setting is 1. If the number is 0 (zero), the command continues to run until you interrupt it by pressing Ctrl-C.

- `-max <integer>` - Maximum Number of Instances
  Specifies the maximum number of workloads to display. The default setting is 25.

**Examples**
The following example displays workload statistics:

```
cluster1::> statistics workload show
cluster1 : 12/31/2013 16:00:04

*Total Read Write Other   Read Write Latency

```

**Storage Commands**

Manage physical storage, including disks, aggregates, and failover

The storage commands enable you to manage physical and logical storage, including disks and storage aggregates. They also enable you to manage storage failover.
Storage aggregate Commands

Manage storage aggregates

The `storage aggregate` command family manages aggregates. The storage aggregate commands can create new aggregates, add more disks to an aggregate, delete the existing ones, change aggregate status and apply options to an aggregate. Aggregate commands often affect the volumes contained within aggregates.

An aggregate name can contain letters, numbers, and the underscore character(_), but the first character must be a letter or underscore. A maximum of 100 aggregates can be created on each node.

An aggregate may be online, restricted, iron_restricted, or offline. When an aggregate is offline, no read or write access is allowed. When an aggregate is restricted, certain operations are allowed (parity recomputation or RAID reconstruction) but data access is not allowed.

Aggregates can be in combinations of the following raid status:

- **normal**
  The aggregate is in a normal state.

- **copying**
  The aggregate is currently the target aggregate of an active aggr copy operation.

- **ironing**
  A WAFL consistency check is being performed on this aggregate.

- **degraded**
  The aggregate contains at least one degraded RAID group that is not being reconstructed.

- **mirror degraded**
  The aggregate is a mirrored aggregate, and one of its plexes is offline or resyncing.

- **growing**
  Disks are in the process of being added to the aggregate.

- **initializing**
  The aggregate is in the process of being initialized.

- **invalid**
  The aggregate does not contain any volume and no volume can be added to it. Typically, this happens after an aborted aggregate copy operation.

- **needs check**
  A WAFL consistency check needs to be performed on the aggregate.

- **partial**
  The aggregate contains at least one disk, however, two or more disks are missing.

- **reconstruct**
  At least one RAID group in the aggregate is being reconstructed.

- **raid0**
  The aggregate consists of RAID-0 (no parity) RAID groups (V-Series and NetCache only).

- **raid4**
  The aggregate consists of RAID-4 RAID groups.
raid_dp
The aggregate consists of RAID-DP (Double Parity) RAID groups.

raid_tec
The aggregate consists of RAID-TEC (Triple Erasure Code) RAID groups.

redirect
A reallocation process optimized the layout of blocks in the aggregate. You cannot clear this status.

wafl inconsistent
The aggregate has been marked corrupted. Please contact technical support if you see an aggregate in this state.

storage aggregate add-disks
Add disks to an aggregate

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The storage aggregate add-disks command adds disks to an existing aggregate. You must specify the number of disks or provide a list of disks to be added. If you specify the number of disks without providing a list of disks, the system selects the disks.

Parameters
-aggregate <aggregate name> - Aggregate
This parameter specifies the aggregate to which disks are to be added.

[-diskcount <integer>] - Disk Count
This parameter specifies the number of disks that are to be added to the aggregate.

{ [-disktype | -T] [ATA | BSAS | FCAL | FSAS | LUN | MSATA | SAS | SSD | VMDISK]} - Disk Type
This parameter specifies the type of disk that is to be added. It must be specified with the -diskcount parameter when adding disks to a Flash Pool.

Use this parameter when adding spare SSDs to an aggregate to convert it to a Flash Pool.

Note: Only the aggregates marked as hybrid-enabled can be converted to Flash Pools. Use storage aggregate modify to mark the aggregate as hybrid-enabled.

{ [-diskclass | -C] [capacity | performance | archive | solid-state | array | virtual]} - Disk Class
This parameter specifies the class of disk that is to be added. All disks that belong to the specified class are considered eligible for selection. The possible values are:

- capacity = Capacity-oriented, near-line disk types. Includes disk types FSAS, BSAS and ATA.
- performance = Performance-oriented, enterprise class disk types. Includes disk types FCAL and SAS.
- archive = Archive class SATA disks in multi-disk carrier storage shelves. Includes disk type MSATA.
- solid-state = Solid-state drives. Includes disk type SSD.
- array = Logical storage devices backed by storage arrays and used by Data ONTAP as disks. Includes disk type LUN.
- virtual = Virtual disks that are formatted and managed by VMware ESX. Includes disk type VMDISK.
[-chksumstyle <aggrChecksumStyle>] - Checksum Style
This parameter specifies the checksum style for the disks to be added to an aggregate. It is not applicable if -disklist or -mirror-disklist is specified. The possible values are block for block checksum and advanced_zoned for advanced zoned checksum (AZCS). By default, disks with the same checksum style as the aggregate are selected. This behavior can be overridden by using this parameter to create a mixed checksum aggregate. A mixed checksum aggregate can support only the block and advanced_zoned checksum styles.

[-disksize <integer>] - Disk Size(GB)
This parameter specifies the size, in GB, of the disks that are to be added to the aggregate. Disks with a usable size between 90% and 105% of the specified size are selected.

[[-disklist] [-d <disk path name>, ...]] - Disks
This parameter specifies a list of disks to be added. If you specify the -disklist parameter, you cannot further qualify the list of disks to be added by count, checksum style, size or type.

[-mirror-disklist <disk path name>, ...] - Disks for Mirrored Plex
This parameter specifies a list of mirror disks to be added. It must contain the same number of disks specified in -disklist parameter. If you specify the -mirror-disklist parameter, you cannot further qualify the list of disks to be added by count, checksum style or type.

[[-ignore-pool-checks [true]]] - Don’t Enforce Plex Pool Best Practices
The disks in a plex are normally required to come from the same SyncMirror pool. This behavior can be overridden with this parameter when it is set to true.

[-allow-mixed-rpm | -f [true]] - Allow Disks With Different RPM Values
This parameter specifies whether disks that have different RPM values can be added. For example, SAS disks can rotate at 10,000 or 15,000 RPM. If this parameter is set to true and a list of disks are provided by using the -disklist parameter, the disks will be added even if the SAS disks you specify have different RPM values. This parameter works similarly for ATA disks, which can rotate at 5,400 or 7,200 RPM.

Note: This parameter is applicable only when the -disklist or -mirror-disklist parameter is used.

[-allow-same-carrier [true]] - Allow Same RAID Group Within Carrier
This parameter can be used to allow two disks housed in the same carrier to be in the same RAID group when you add disks to an aggregate.

Having disks in the same carrier in the same RAID group is not desirable because a carrier failure can cause a simultaneous outage for two disks in the same RAID group. You can add a disk to an aggregate that causes this situation, but when an alternate disk becomes available, Data ONTAP automatically initiates a series of disk copy operations to put the disks into different RAID groups. For this reason, you should use this parameter only when necessary. When possible, allow Data ONTAP to choose disks that need to be added to the aggregate.

This parameter affects only the add-disks operation. It is not a persistent attribute of the aggregate.

[-storage-pool <storage pool name>] - Storage Pool
This parameter specifies the name of the SSD storage pool from which available allocation units are added to a given aggregate. This parameter cannot be used with the -disk-list or -disk-count parameters.

[-allocation-units <integer>]] - Allocation Units
This parameter specifies the number of allocation units to be added to a given aggregate from an SSD storage pool. Number of allocation units available and size of each unit can be found using the storage pool show-available-capacity command. This parameter works only when you also use the -storage-pool parameter.

[-simulate | -n [true]] - Simulate Addition of Disks
This parameter is used with the disktype and diskcount parameters to determine which disks would be added without actually performing the addition of disks operation.
This command allows the administrator to add disks to an existing aggregate. The command requires the following parameters:

[-raidgroup | -g {new|all|<raidgroup>}] - RAID Group

This parameter enables the administrator to specify which RAID group will receive the added disks. If this parameter is not used, the disks are added to the most recently created RAID group until it is full, then new RAID groups are created and filled until all the disks are added. If a RAID group name \( rgX \) is specified, the disks are added to that RAID group. If \( new \) is specified, the disks are added to a new RAID group, even if the disks would fit into an existing RAID group. If \( all \) is specified, the disks are added to existing RAID groups until all existing RAID groups are full. Then Data ONTAP creates one or more new RAID groups and adds the remaining disks to the new groups. If the disk type or checksum style parameters are specified with this parameter, the command operates only on the RAID groups with the matching disk type or checksum style, even if \( all \) is specified.

[-cache-raid-group-size <integer>] - RAID Group Size for Cache Tier

This parameter specifies the maximum number of disks that can be included in an SSD RAID group for this aggregate.

Note: This parameter is applicable only when adding SSDs for the first time to a hybrid-enabled aggregate. If this parameter is not used when the first SSDs are added to the aggregate, the maximum RAID group size for the SSD cache is set to the default SSD RAID group size for the RAID type of the SSD cache.

[-raidtype | -t {raid_tec|raid_dp|raid4}] - RAID Type

This parameter specifies the type for the new RAID groups that would be created while adding disks to the aggregate. Use this parameter when you add the first RAID group comprised of SSDs to a hybrid-enabled aggregate. The values are \( raid4 \) for RAID4, \( raid_dp \) for RAID Double Parity, and \( raid_tec \) for RAID-TEC. The default value is the type of RAID groups of the aggregate, except for RAID-TEC hybrid-enabled aggregates where the SSD tier will default to \( raid_dp \). An aggregate might include a mix of different RAID types.

Examples

The following example adds 10 disks to an aggregate named \( aggr0 \). The disks are added to a RAID group named \( rg1 \):

```
cluster1::> storage aggregate add-disks -aggregate aggr0 -diskcount 10 -raidgroup rg1
```

In this example, an aggregate is converted to a Flash Pool aggregate using SSD capacity from a storage pool. The aggregate was created using RAID-DP for the hard disks and the SSDs are added using RAID4.

```
cluster1::> storage aggregate add-disks -aggregate FlashPool -storage-pool SP1 -allocation-units 1 -raidtype raid4
```

- `storage pool show-available-capacity` on page 862

**storage aggregate create**

Create an aggregate

Availability: This command is available to *cluster* administrators at the *admin* privilege level.

Description

The `storage aggregate create` command creates an aggregate. An aggregate consists of disks. You must specify the number of disks or provide a list of disks to be added to the new aggregate. If you specify the number of disks without providing a list of disks, the system selects the disks.
When creating an aggregate, you can optionally specify the aggregate's home node, the RAID type for RAID groups on the aggregate, the maximum number of disks that can be included in a RAID group, and whether the aggregate's contents are encrypted.

**Parameters**

- **aggregate <aggregate name>** - Aggregate
  
  This parameter specifies the name of the aggregate that is to be created.

- **chksumstyle <aggrChecksumStyle>** - Checksum Style
  
  This parameter specifies the checksum style for the aggregate. The values are *block* for Block Checksum and *advanced_zoned* for Advanced Zoned Checksum (AZCS).

- **diskcount <integer>** - Number Of Disks
  
  This parameter specifies the number of disks that are to be included in the aggregate, including the parity disks. The disks in this newly created aggregate come from the pool of spare disks. The smallest disks in this pool are added to the aggregate first, unless you specify the `-disksize` parameter.

- **diskrpm | -R <integer>** - Disk RPM
  
  This parameter specifies the RPM of the disks on which the aggregate is to be created. The possible values include 5400, 7200, 10000, and 15000.

- **disksize <integer>** - Disk Size(GB)
  
  This parameter specifies the size, in GB, of the disks on which the aggregate is to be created. Disks with a usable size between 90% and 105% of the specified size are selected.

- **disktype | -T {ATA | BSAS | FCAL | FSAS | LUN | MSATA | SAS | SSD | VMDISK}** - Disk Type
  
  This parameter specifies the type of disk on which the aggregate is to be created.

- **diskclass | -C {capacity | performance | archive | solid-state | array | virtual}** - Disk Class
  
  This parameter specifies the class of disks on which the aggregate is to be created. All disks that belong to the specified class are considered eligible for selection. The possible values are:

  - **capacity** = Capacity-oriented, near-line disk types. Includes disk types FSAS, BSAS and ATA.
  - **performance** = Performance-oriented, enterprise class disk types. Includes disk types FCAL and SAS.
  - **archive** = Archive class SATA disks in multi-disk carrier storage shelves. Includes disk type MSATA.
  - **solid-state** = Solid-state drives. Includes disk type SSD.
  - **array** = Logical storage devices backed by storage arrays and used by Data ONTAP as disks. Includes disk type LUN.
  - **virtual** = Virtual disks that are formatted and managed by VMware ESX. Includes disk type VMDISK.

- **mirror | -m [true]** - Mirror
  
  This parameter specifies that the new aggregate be mirrored (have two plexes). If this parameter is set to `true`, the specified disks are split between the two plexes. By default, the new aggregate will not be mirrored. You cannot use the `-mirror` parameter when supplying a specific list of disks with either the `-disklist` or `-mirror-disklist` parameters.

- **pool <aggrSparePool>** - Spare Pool
  
  This parameter specifies the SyncMirror pool to be used to supply the disks for the aggregate. Valid values are Pool0 or Pool1.
This parameter specifies a list of disks to be added to the new aggregate. If you specify the `disklist` parameter, you cannot further qualify the list of disks to be added by count, checksum style, type, size, or RPM. You cannot use the `disklist` parameter when the `mirror` parameter is set to `true`.

This parameter specifies a list of mirror disks to be added to the new mirrored aggregate. It must contain the same number of disks specified in `disklist` parameter. If you specify the `mirror-disklist` parameter, you cannot further qualify the list of disks to be added by count, checksum style, type, size, or RPM. You cannot use the `mirror-disklist` parameter when the `mirror` parameter is set to `true`.

This parameter specifies a list of disks to be added to the new aggregate. If you specify the `disklist` parameter, you cannot further qualify the list of disks to be added by count, checksum style, type, size, or RPM. You cannot use the `disklist` parameter when the `mirror` parameter is set to `true`.

This parameter specifies whether the aggregate can contain disks that have different RPM values. For example, SAS disks can rotate at 10,000 or 15,000 RPM. If this parameter is set to `true` and a list of disks are provided by using the `disklist` parameter, the aggregate will be created even if the SAS disks you specify have different RPM values. This parameter works similarly for ATA disks, which can rotate at 5,400 or 7,200 RPM.

This parameter can be used to allow two disks housed in the same carrier to be in the same RAID group when you add disks to an aggregate.

Having disks in the same carrier in the same RAID group is not desirable because a carrier failure can cause a simultaneous outage for two disks in the same RAID group. You create an aggregate with this characteristic, but when an alternate disk becomes available, Data ONTAP automatically initiates a series of disk copy operations to put the disks into different RAID groups. For this reason, you should use this parameter only when necessary. When possible, allow Data ONTAP to choose the disks from which to create the aggregate.

This parameter affects only the aggregate creation operation. It is not a persistent attribute of the aggregate.

This parameter specifies the home node for the aggregate. If this parameter is not specified, Data ONTAP selects the node where the aggregate is created.

This parameter specifies the maximum number of disks that can be included in a RAID group.

This parameter specifies the type for RAID groups on the aggregate. The values are `raid4` for RAID4, `raid_dp` for RAID Double Parity, and `raid_tec` for RAID Triple-Erasure-Code. The default setting is `raid_dp` unless the disks are HDDs with a capacity larger than 4 TB, in which case the default will be `raid_tec`. This parameter is not needed for array LUNs because they are always created with the `raid0` raidtype.

This option simulates the aggregate creation and prints the layout of the new aggregate.

This parameter can be used to force the creation of a 2-disk RAID4 aggregate, or a 3-disk or 4-disk RAID-DP aggregate.

This specifies whether the aggregate will be considered by the Auto Balance Aggregate feature. If the Auto Balance Aggregate feature is not used, this field is not used. When this parameter is set to `true` the Auto Balance Aggregate feature might recommend moving volumes to or from this aggregate in order to balance
system workload. When this parameter is set to `false` the aggregate will not be considered as a destination for the Auto Balance Aggregate feature allowing for predictability in data placement. The default value is `false`.

`[-encrypt [true]]` - Enable Encryption

This parameter specifies that the new aggregate be encrypted. If this parameter is set to `true`, the specified aggregate's contents will be encrypted.

`[-snaplock-type | -L {non-snaplock|compliance|enterprise}]` - SnapLock Type

This parameter specifies the type of SnapLock aggregate to be created. In order to create a SnapLock Compliance aggregate, specify `compliance`. To create a SnapLock Enterprise aggregate, specify `enterprise`.

`[-autobalance-unbalanced-threshold-percent <integer>]` - Threshold When Aggregate Is Considered Unbalanced (%)

This parameter specifies the space used threshold percentage that will cause the Auto Balance Aggregate feature to consider an aggregate as unbalanced.

`[-autobalance-available-threshold-percent <integer>]` - Threshold When Aggregate Is Considered Balanced (%)

This parameter specifies the threshold percentage which will determine if an aggregate is a target destination for a move. The Auto Balance Aggregate feature will attempt to move volumes from an unbalanced aggregate until it is under this percentage.

### Examples

The following example creates an aggregate named `aggr0` on a home node named `node0`. The aggregate contains 20 disks and uses RAID-DP. The aggregate contains regular FlexVol volumes:

```
cluster1::> storage aggregate create -aggregate aggr0 -nodes node0
   -diskcount 20 -raidtype raid_dp -volume-style flex
```

The following example creates an aggregate named `aggr0` on a home node named `node0`. The aggregate contains the disks specified and uses RAID-DP:

```
cluster1::> storage aggregate create -aggregate aggr0 -nodes node0
   -disklist 1.0.15,1.0.16,1.0.17,1.0.18,1.0.19 -raidtype raid_dp
```

The following example creates an aggregate named `aggr0` on a home node named `node0`. The aggregate contains 20 disks of size 6 TB and of type FSAS and uses RAID-TEC:

```
cluster1::> storage aggregate create -aggregate aggr0 -nodes node0
   -diskcount 20 -raidtype raid_tec -disksize 6000 -disktype FSAS
```

The following example creates a mirrored aggregate named `aggr0` on the local node. The aggregate contains 10 disks in each plex:

```
cluster1::> storage aggregate create -aggregate aggr0 -mirror
   -diskcount 20
```

The following example creates an aggregate named `aggr1` on the local node. The aggregate contains 3 disks and is encrypted

```
cluster1::> storage aggregate create -aggregate aggr1 -diskcount 3 -encrypt true
```
storage aggregate delete

Delete an aggregate

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The storage aggregate delete command deletes a storage aggregate. No volumes can exist on an aggregate that is to be deleted; the command fails if volumes are present on the aggregate. The command prompts you for confirmation before running. You can use the set command with the -confirmations off parameter to disable confirmation messages.

Parameters
-aggregate <aggregate name> - Aggregate
   This parameter specifies the aggregate that is to be deleted.

[-preserve-config-data [true]] - Delete Physical Aggregate but Preserve Configuration Data (privilege: advanced)
   Deletes the physical aggregate, but preserves the aggregate configuration data. The aggregate must not have any disks associated with it. If the parameter -preserve-config-data is specified without a value, the default value is true; if this parameter is not specified, the default value is false.

Examples
The following example deletes an aggregate named aggr1:

   cluster1::> storage aggregate delete -aggregate aggr1

Related references
   set on page 4

storage aggregate mirror

Mirror an existing aggregate

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The storage aggregate mirror command adds a plex to an existing unmirrored aggregate. You can specify a list of disks to be used for the mirrored plex. If you do not specify the disks, the system automatically selects the disks based on the aggregate's existing plex.

Parameters
-aggregate <aggregate name> - Aggregate
   This parameter specifies the aggregate to mirror.

[-allow-mixed-rpm | -f [true]] - Allow Disks With Different RPM Values
   This parameter specifies whether disks that have different RPM values can be used. For example, SAS disks can rotate at 10,000 or 15,000 RPM. If this parameter is set to true and a list of disks are provided by using the -mirror-disklist parameter, the disks will be added even if the SAS disks you specify have different RPM values. This parameter works similarly for ATA disks, which can rotate at 5,400 or 7,200 RPM.

   Note: This parameter is only applicable when the -mirror-disklist parameter is used.
[-mirror-disklist | -d <disk path name>, ...] - Disks for Mirrored Plex

This parameter specifies a list of disks to be used for the plex to be added. It must contain the same number of disks as the existing plex of the unmirrored aggregate specified using the -aggregate parameter.

[-ignore-pool-checks [true]] - Don't Enforce Plex Pool Best Practices

For maximum reliability, all disks from a plex should come from the same SyncMirror pool, and the disks for the second plex should all come from the other pool. If needed, this behavior can be overridden by setting this parameter to true. This parameter can be used only with the -mirror-disklist parameter.

[-allow-same-carrier | -f [true]] - Allow Same RAID Group Within Carrier

This parameter can be used to allow two disks housed in the same carrier to be in the same RAID group for a mirrored aggregate. Having disks in the same carrier in the same RAID group is not desirable, because a carrier failure can cause a simultaneous outage for two disks in the same RAID group. For this reason, this configuration is not allowed by default. This restriction can be overridden by setting this parameter to true.

Note: This parameter is accepted only when the -mirror-disklist parameter is used.

[-simulate | -n [true]] - Simulate Mirroring of an Existing Aggregate

This option simulates the mirroring of an existing aggregate and prints the layout of the new plex.

Examples

The following example mirrors an unmirrored aggregate aggr1:

```
cluster1::> storage aggregate mirror -aggregate aggr1
```

The following example mirrors an unmirrored aggregate aggr1. The specified disks are used for the new plex.

```
cluster1::> storage aggregate mirror -aggregate aggr1 -mirror-disklist 1.2.12, 1.2.14, 1.2.16
```

storage aggregate modify

Modify aggregate attributes

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The `storage aggregate modify` command can be used to modify attributes of an aggregate such as RAID type and maximum RAID group size.

Changing the RAID type immediately changes the RAID group type for all RAID groups in the aggregate.

Changing the maximum RAID size does not cause existing RAID groups to grow or to shrink; rather, it affects the size of RAID groups created in the future, and determines whether more disks can be added to the RAID group that was most recently created.

Parameters

- **-aggregate <aggregate name>** - Aggregate
  
  This parameter specifies the storage aggregate that is to be modified.

- **[-disktype | -T {ATA | BSAS | FCAL | FSAS | LUN | MSATA | SAS | SSD | VMDISK}]** - Disk Type
  
  This parameter specifies either the HDD tier or the SSD tier when changing the RAID type of a Flash Pool. If the HDD tier is composed of more than one type of disk, specifying any of the disk types in use causes that tier to be modified.
[-free-space-realloc {on|off}] - Free Space Reallocation

This parameter specifies whether free space reallocation is enabled on the aggregate.

Free space reallocation optimizes the free space in an aggregate immediately before Data ONTAP writes data to the blocks in that aggregate.

The default setting is off.

[-ha-policy {sfo|cfo}] - HA Policy

This parameter specifies the high-availability policy to be used in the context of a root recovery procedure. Do not modify this setting unless directed to do so by a customer support representative.

[-percent-snapshot-space <percent>] - Space Reserved for Snapshot Copies

This parameter is used to set the space reserved for Snapshot copies to the specified value. For example, to set the snapshot reserve to 5%, you should enter -percent-snapshot-space 5.

[-space-nearly-full-threshold-percent <percent>] - Aggregate Nearly Full Threshold Percent

This optionally specifies the percentage at which the aggregate is considered nearly full, and above which an EMS warning will be generated. The default value is 95%. The maximum value for this option is 99%. Setting this threshold to 0 disables the aggregate nearly full space alerts.

[-space-full-threshold-percent <percent>] - Aggregate Full Threshold Percent

This optionally specifies the percentage at which the aggregate is considered full, and above which a critical EMS error will be generated. The default value is 98%. The maximum value for this option is 100%. Setting this threshold to 0 disables the aggregate full space alerts.

[-hybrid-enabled {true|false}] - Hybrid Enabled

If the hybrid-enabled option is set to "true", the aggregate is marked as hybrid_enabled, that is, the aggregate can contain a mix of SSDs and HDDs (Hard Disk Drives, e.g., SAS, SATA, and/or FC). By default, aggregates cannot be marked "hybrid_enabled" if the aggregate contains FlexVols that cannot be write cached. A FlexVol cannot be write-cached if it is part of an aggregate created in Data ONTAP 7. Use -force-hybrid-enabled to over-ride this behavior.

[-force-hybrid-enabled | -f {true}] - Force Marking of Aggregate as Hybrid Enabled

By default, aggregates cannot be marked "hybrid_enabled" if the aggregate contains FlexVols that cannot be write cached. A FlexVol cannot be write-cached if it is part of an aggregate created in Data ONTAP 7. Use -force-hybrid-enabled to over-ride this behavior. Note that read caching will be enabled on these FlexVols, but write caching will be disabled. Setting this parameter to true would mark the aggregate as hybrid_enabled; this means that the aggregate can contain a mix of SSDs and HDDs (Hard Disk Drives, for example, SAS, SATA and/or FC). This parameter is used to force marking aggregates which have FlexVols that cannot be write cached as hybrid enabled. FlexVols in the aggregate marked as hybrid enabled using this parameter which cannot participate in write-caching will only have read-caching enabled. All other FlexVols in the aggregate can participate in both read and write caching.

[-maxraidsize | -s <integer>] - Max RAID Size

This parameter specifies the maximum number of disks that can be included in a RAID group for this aggregate.

Note: For Flash Pools, this option controls the maximum size of the HDD RAID groups.

[-cache-raid-group-size <integer>] - Flash Pool SSD Tier Maximum RAID Group Size

This parameter specifies the maximum number of disks that can be included in a SSD RAID group for this Flash Pool.

Note: This parameter is applicable only for Flash Pools.

[-raidtype | -t {raid_tec|raid_dp|raid4}] - RAID Type

This parameter specifies the RAID type for RAID groups on the aggregate. The possible values are raid4 for RAID4, raid_dp for RAID-DP, and raid_tec for RAID-TEC. If you change the RAID type from RAID4 to
RAID-DP, each RAID group allocates a spare disk for the group's second parity disk and begins a reconstruction process. If you change the RAID type from RAID-DP to RAID-TEC, each RAID group allocates a spare disk for the group's third parity disk and begins a reconstruction process. Changing the RAID type from RAID4 to RAID-TEC or vice-versa is not supported. To change the RAID type from RAID4 to RAID-TEC, first change from RAID4 to RAID-DP and then to RAID-TEC.

[-resyncsnaptime <integer>] - SyncMirror Resync Snapshot Frequency in Minutes
This parameter sets the mirror resynchronization snapshot frequency to be the given number of minutes. The default value is 60 (minutes).

[-state <aggregate state>] - State
This deprecated parameter specifies the state of the aggregate. The possible values are as follows:

- online - Immediately sets the aggregate online. All volumes on the aggregate are set to the state they were in when the aggregate was taken offline or restricted. The preferred command to bring an aggregate online is storage aggregate online.
- offline - Takes an aggregate offline. You cannot take an aggregate offline if any of its volumes are online. The preferred command to take an aggregate offline is storage aggregate offline.
- restricted - Restricts the aggregate. You cannot restrict an aggregate if any of its volumes are online. The preferred command to restrict an aggregate is storage aggregate restrict.

[-is-autobalance-eligible {true|false}] - Is Eligible for Auto Balance Aggregate (privilege: advanced)
This specifies whether the aggregate is considered by the Auto Balance Aggregate feature. If the Auto Balance Aggregate feature is not used, this field is not used. When this parameter is set to true the Auto Balance Aggregate feature might recommend moving volumes to or from this aggregate in order to balance system workload. When this parameter is set to false the aggregate will not be considered as a destination for the Auto Balance Aggregate feature allowing for predictability in data placement. The default value is false.

[-autobalance-unbalanced-threshold-percent <integer>] - Threshold When Aggregate Is Considered Unbalanced (%) (privilege: advanced)
This parameter sets the space used threshold percentage that will cause the Auto Balance Aggregate feature to consider an aggregate as unbalanced.

[-autobalance-available-threshold-percent <integer>] - Threshold When Aggregate Is Considered Balanced (%) (privilege: advanced)
This parameter sets the threshold percentage which will determine if an aggregate is a target destination for a move. The Auto Balance Aggregate feature will attempt to move volumes from an unbalanced aggregate until it is under this percentage.

[-resync-priority {high(fixed)|high|medium|low}] - Resynchronization Priority
This parameter specifies the new resynchronization priority value for the specified aggregate. This field cannot be modified for unmirrored or Data ONTAP system aggregates.

Possible values for this parameter are:

- high: Mirrored data aggregates with this priority value start resynchronization first.
- medium: Mirrored data aggregates with this priority value start resynchronization after all the system aggregates and data aggregates with 'high' priority value have started resynchronization.
- low: Mirrored data aggregates with this priority value start resynchronization only after all the other aggregates have started resynchronization.

Examples
The following example changes all RAID groups on an aggregate named aggr0 to use RAID-DP:

*storage aggregate scrub* on page 680

**storage aggregate offline**

Offline an aggregate

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**
The *storage aggregate offline* command takes an aggregate offline.

If you are taking a root aggregate offline, the node owning the aggregate must be in maintenance mode.

**Parameters**

- **-aggregate <aggregate name>** - Aggregate
  
The name of the aggregate to be taken offline.

**Examples**

The following example takes an aggregate named *aggr1* offline:

```
cluster1::> storage aggregate offline -aggregate aggr1
```

The following example takes an aggregate named *aggr1* offline by unmounting its volumes:

```
cluster1::*> storage aggregate offline -aggregate aggr1 -unmount-volumes true
```

Related references

*storage aggregate online* on page 678

**storage aggregate online**

Online an aggregate

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**
The *storage aggregate online* command brings an aggregate online if the aggregate is in offline or restricted state. If an aggregate is in an inconsistent state, it must be brought to a consistent state before it can be brought online. If you have an aggregate that is in an inconsistent state, contact technical support.

**Parameters**

- **-aggregate <aggregate name>** - Aggregate
  
The name of the aggregate to be brought online.
Related references

- storage aggregate offline on page 678
- storage aggregate restrict on page 680

storage aggregate remove-stale-record

Remove a stale aggregate record

Availability: This command is available to cluster administrators at the advanced privilege level.

Description

The `storage aggregate remove-stale-record` command removes a stale storage aggregate record on disk. A stale aggregate record refers to an aggregate that has been removed from the storage system, but whose information remains recorded on disk. Stale aggregate records are displayed in the nodeshell aggr status -r command, but the storage aggregate show command does not show the aggregate as hosted on that node.

Parameters

- `-aggregate <aggregate name>` - Aggregate
  
  This parameter specifies the aggregate that corresponds to the stale aggregate record that is to be deleted.

- `-nodename (<nodename>|local)` - Node Name
  
  This parameter specifies the node that contains the aggregate.

Examples

The following example removes a stale aggregate record that refers to aggregate "aggr1":

```
cluster1::> storage aggregate remove-stale-record -aggregate aggr1 -nodename node1
```

storage aggregate rename

Rename an aggregate

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The `storage aggregate rename` command renames an aggregate.

Parameters

- `-aggregate <aggregate name>` - Aggregate
  
  This parameter specifies the aggregate to be renamed.

- `-newname <aggregate name>` - New Name
  
  This parameter specifies the new name for the aggregate.
storage aggregate restrict

Restrict an aggregate

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The storage aggregate restrict command puts an aggregate in restricted state to make data in the aggregate's volumes unavailable to clients. When an aggregate is in restricted state data access is not allowed. However, few operations such as aggregate copy, parity recomputation, scrub and RAID reconstruction are allowed. You can also use this command if you want the aggregate to be the target of an aggregate copy or SnapMirror replication operation.

Parameters
-aggregate <aggregate name> - Aggregate
The name of the aggregate to be restricted.

Examples
The following example restricts an aggregate named aggr1:

cluster1::> storage aggregate restrict -aggregate aggr1

The following example restricts an aggregate named aggr2 by unmounting all the volumes within the aggregate:

cluster1::*> storage aggregate restrict -aggregate aggr2 -unmount-volumes true

Related references
storage aggregate show on page 682

storage aggregate scrub

Aggregate parity scrubbing

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The storage aggregate scrub command scrubs an aggregate for media and parity errors. Parity scrubbing compares the data disks to the parity disks in their RAID group and corrects the parity disks contents, as required. If no name is given, parity scrubbing is started on all online aggregates.

Note: By default, scrubs are scheduled to run for a specified time on a weekly basis. However, you can use this command to run scrubs manually to check for errors and data inconsistencies.

Parameters
{-aggregate <aggregate name> - Aggregate
This parameter specifies the aggregate to be scrubbed for errors.
This parameter specifies the name of the plex to scrub. If this parameter is not specified, the command scrubs the entire aggregate.

**[-raidgroup {<text>}] - RAID Group**

This parameter specifies the RAID group to be scrubbed. If this parameter is not specified, the command scrubs the entire aggregate.

**Note:** This parameter is only applicable when the `-plex` parameter is used.

**[-node {<nodename>|local}] - Node**

This parameter specifies the name of the node associated with the aggregate to be scrubbed. The value `local` specifies the current node.

**-action {start|stop|resume|suspend|status} - Action**

This parameter specifies the action to be taken. The possible actions are:

- **start** - Starts a scrub.
- **stop** - Permanently stops a scrub. A stopped scrub cannot be resumed.
- **resume** - Resumes a suspended parity scrub.
- **suspend** - Suspends a parity scrub.
- **status** - Displays the current status of a scrub.

### Examples

The following example starts a scrub on a RAID group named rg0 of plex named plex0 on an aggregate named aggr0:

```
cluster1::> storage aggregate scrub -aggregate aggr0 -raidgroup rg0 -plex plex0 -action start
```

The following example queries the status of a scrub:

```
cluster1::> storage aggregate scrub -aggregate aggr0 -raidgroup rg0 -plex plex0 -action status
```

```
Raid Group:/aggr0/plex0/rg0, Is Suspended:false, Last Scrub:Sun Nov 13 01:30:55 2011, Percentage Completed:7%
```

The following example starts a scrub on plex1 of an aggregate named aggr1:

```
cluster1::> storage aggregate scrub -aggregate aggr1 -plex plex1 -action start
```

The following example queries the status of plex1 of an aggregate named aggr1:

```
cluster1::> storage aggregate scrub -aggregate aggr1 -plex plex1 -action status
```

```
Raid Group:/aggr1/plex1/rg0, Is Suspended:false, Last Scrub:Sun Nov 13 02:07:29 2011, Percentage Completed:1%
```

The following example queries the status of all the plexes for an aggregate named aggr1:

```
cluster1::> storage aggregate scrub -aggregate aggr1 -action status
```

```
Raid Group:/aggr1/plex0/rg0, Is Suspended:false, Last Scrub:Sun Nov 13 01:58:06 2011
```

**Storage aggregate Commands**

681
storage aggregate show

Display a list of aggregates

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The storage aggregate show command displays information about aggregates. The command output depends on the parameter or parameters specified with the command. If no parameters are specified, the command displays the following information about all aggregates:

- Aggregate name
- Size
- Available size
- Percentage used
- State
- Number of volumes
- Node on which the aggregate is located
- RAID status

To display detailed information about a single aggregate, use the -aggregate parameter.

Parameters

{| -fields <fieldname>, ...
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

| -checksum
If this parameter is specified, the command displays information about the checksum for all aggregates in the cluster:

- Aggregate name
- Checksum status (active, off, reverting, none, unknown, initializing, reinitializing, reinitialized, upgrading_phase1, upgrading_phase2)
- Checksum style (none, advanced_zoned, block, mixed, WAFL, or unknown)

| -disk
If this parameter is specified, the command displays disk names for all aggregates in the cluster:

- Aggregate name
- Number and names of disks in the aggregate

| -raid-info
If this parameter is specified, the command displays information about RAID groups, RAID type, maximum RAID size, checksum state, checksum style and whether the RAID status is inconsistent.
If this parameter is specified, the command displays detailed information about all aggregates in the cluster.

-aggregate <aggregate name> - Aggregate
If this parameter is specified, the command displays detailed information about the specified aggregate.

-storage-type {hdd | hybrid | lun | ssd | vmdisk} - Storage Type
If this parameter is specified, the command displays information only about the aggregates with the specified storage type. The possible values are hdd, hybrid, lun, ssd and vmdisk.

-chksumstyle <aggrChecksumStyle> - Checksum Style
If this parameter is specified, the command displays information only about the aggregates that use the specified checksum style.

-diskcount <integer> - Number Of Disks
If this parameter is specified, the command displays information only about the aggregates that have the specified number of disks.

-mirror | -m [true] - Mirror
If this parameter is specified, the command displays information only about the aggregates that have the specified mirrored value.

-disklist | -d <disk path name>, ... - Disks for First Plex
If this parameter is specified, the command displays information only about the aggregates that have the specified disk or disks.

-mirror-disklist <disk path name>, ... - Disks for Mirrored Plex
If this parameter is specified, the command displays information only about the aggregates that have the specified disk or disks present in the mirrored plex.

-node {<nodename>|local} - Node
If this parameter is specified, the command displays information only about the aggregates that are located on the specified node.

-free-space-realloc {on|off} - Free Space Reallocation
If this parameter is specified, the command displays whether free space reallocation is enabled on the specified aggregate.

-ha-policy {sfo|cfo} - HA Policy
This optionally specifies the high-availability policy to be used in the context of a root recovery procedure. Do not modify this setting unless directed to do so by a customer support representative.

-percent-snapshot-space <percent> - Space Reserved for Snapshot Copies
If this parameter is specified, the command displays information only about the aggregates that have the specified space reserved for Snapshot copies.

-space-nearly-full-threshold-percent <percent> - Aggregate Nearly Full Threshold Percent
If this parameter is specified, the command displays information only about the aggregates that have the specified nearly full threshold percent.

-space-full-threshold-percent <percent> - Aggregate Full Threshold Percent
If this parameter is specified, the command displays information only about the aggregates that have the specified full threshold percent.

-hybrid-enabled {true|false} - Hybrid Enabled
If this parameter is specified, the command displays information only about the aggregates that are eligible to contain both SSD and non-SSD RAID groups.
[-availsize <integer>[KB|MB|GB|TB|PB]] - Available Size

If this parameter is specified, the command displays information only about the aggregates that have the specified available size.

[-chksumenabled {true|false}] - Checksum Enabled

If this parameter is specified, the command displays information only about the aggregates that have the specified checksum setting.

[-chksumstatus <text>] - Checksum Status

If this parameter is specified, the command displays information only about the aggregates that have the specified checksum status. The possible values for checksum status include the following: active, off, reverting, none, unknown, initializing, reinitializing, reinitialized, upgrading_phase1, and upgrading_phase2.

[-cluster <text>] - Cluster

If this parameter is specified, the command displays information only about the aggregates that are owned by nodes in the specified cluster. By default, only local cluster aggregates are displayed.

[-cluster-id <UUID>] - Home Cluster ID

If this parameter is specified, the command displays information only about the aggregates that are owned by nodes in the cluster specified by the cluster UUID. By default, only local cluster aggregates are displayed.

[-dr-home-id <integer>] - DR Home ID

If this parameter is specified, the command displays information only about the aggregates whose Disaster Recovery home node has the specified system ID.

[-dr-home-name <text>] - DR Home Name

If this parameter is specified, the command displays information only about the aggregates whose Disaster Recovery home is the specified node.

[-inofile-version <integer>] - Inofile Version (privilege: advanced)

If this parameter is specified, the command displays information only about the aggregates whose inode files are at the specified version.

[-has-mroot {true|false}] - Has Mroot Volume

If this parameter is specified, the command displays information about only the aggregates that contain their owning node's management root directory.

[-has-partner-mroot {true|false}] - Has Partner Node Mroot Volume

If this parameter is specified, the command displays information about only the aggregates that contain the management root directory of their owning node's failover partner.

[-home-id <integer>] - Home ID

If this parameter is specified, the command displays information only about the aggregates whose home node has the specified system ID.

[-home-name <text>] - Home Name

If this parameter is specified, the command displays information only about the aggregates whose home node is the specified node.

[-hybrid-cache-size-total <integer>[KB|MB|GB|TB|PB]] - Total Hybrid Cache Size

If this parameter is specified, the command displays information only about the aggregates that have the specified total cache size in a Flash Pool.

[-hybrid {true|false}] - Hybrid

If this parameter is specified, the command displays information only about the aggregates that currently contain both SSD and non-SSD RAID groups.
[-inconsistent (true|false)] - Inconsistent
   If this parameter is specified, the command displays information only about the aggregates that have the specified consistency.

[-is-home (true|false)] - Is Aggregate Home
   If this parameter is specified, the command displays information only about the aggregates whose home node and owner node have the same system ID.

[-maxraidsize | -s <integer>] - Max RAID Size
   If this parameter is specified, the command displays information only about the aggregates that have the specified maximum number of disks for RAID groups.
   Note: For Flash Pools, this option controls the maximum size of the HDD RAID groups.

[-cache-raid-group-size <integer>] - Flash Pool SSD Tier Maximum RAID Group Size
   If this parameter is specified, the command displays information about the maximum RAID group size for the SSD tier for Flash Pools.
   Note: This parameter is applicable only for Flash Pools.

[-owner-id <integer>] - Owner ID
   If this parameter is specified, the command displays information only about the aggregates that are owned by the node with the specified system ID.

[-owner-name <text>] - Owner Name
   If this parameter is specified, the command displays information only about the aggregates that are owned by the specified node.

[-percent-used <percent>] - Used Percentage
   If this parameter is specified, the command displays information only about the aggregates that have the specified used size, as a percentage.

[-plexes <text>, ...] - Plexes
   If this parameter is specified, the command displays information only about the aggregates that have the specified plex or plexes.

[-raidgroups <text>, ...] - RAID Groups
   If this parameter is specified, the command displays information only about the aggregates that have the specified RAID group or groups.

[-raidstatus <text>] - RAID Status
   If this parameter is specified, the command displays information only about the aggregates that have the specified RAID status. The possible values for RAID status are normal, copying, ironing, degraded, mirror degraded, growing, initializing, invalid, needs check, partial, reconstruct, raid4, raid0, raid_dp, raid_tec, direct, and wafl inconsistent. You can specify multiple values (for example, reconstruct and growing).

[-raidtype | -t {raid_tec|raid_dp|raid4}] - RAID Type
   If this parameter is specified, the command displays information only about the aggregates that use the specified RAID type. The possible values are raid0 for RAID 0, raid4 for RAID4, raid_dp for RAID-DP, raid_tec for RAID-TEC, and mixed_raid_type for aggregates that include a mix of RAID types.

[-resyncsnaptime <integer>] - SyncMirror Resync Snapshot Frequency in Minutes
   If this parameter is specified, the command displays information only about the aggregates whose SyncMirror Resynchronization Snapshot Frequency is the specified value.

[-root (true|false)] - Is Root
   If this parameter is specified, the command displays information about only the root aggregates in the cluster.
- **-sis-metadata-space-used** `<integer> [KB|MB|GB|TB|PB]` - Space Used by Metadata for Volume Efficiency
  If this parameter is specified, the command displays information about only the aggregates with the specified space used by A-SIS metafiles for volume efficiency. This parameter is deprecated in Data ONTAP 8.2 and later. Use the volume-footprint-list-info API for details related to space usage by deduplication metadata.

- **-size** `<integer> [KB|MB|GB|TB|PB]` - Size
  If this parameter is specified, the command displays information only about the aggregates that have the specified size.

- **-state** `<aggregate state>` - State
  If this parameter is specified, the command displays information only about the aggregates that have the specified state.

- **-usedsize** `<integer> [KB|MB|GB|TB|PB]` - Used Size
  If this parameter is specified, the command displays information only about the aggregates that have the specified used size.

- **-uses-shared-disks** `{true|false}` - Uses Shared Disks
  Selects the aggregates that match this parameter value. This parameter is used to list all the aggregates that use shared HDDs or shared SSDs.

- **-uuid** `<text>` - UUID String (privilege: advanced)
  If this parameter is specified, the command displays information only about the aggregate that has the specified UUID. This parameter is available only at the advanced privilege level and higher.

- **-volcount** `<integer>` - Number Of Volumes
  If this parameter is specified, the command displays information only about the aggregates that have the specified number of volumes.

- **-is-autobalance-eligible** `{true|false}` - Is Eligible for Auto Balance Aggregate (privilege: advanced)
  If this parameter is specified, the command displays information only about the aggregates that are considered by the Auto Balance Aggregate feature.

- **-autobalance-state** `<Auto Balance Aggregate state>` - State of the aggregate being balanced (privilege: advanced)
  If this parameter is specified, the command displays information only about the aggregates that have the specified state.

- **-physical-used** `<integer> [KB|MB|GB|TB|PB]` - Total Physical Used Size
  If this parameter is specified, the command displays information only about the aggregates that have the specified physical used size. This differs from `total-used` space by the space that is guaranteed for future writes. The value includes blocks in use by Snapshot copies.

- **-physical-used-percent** `<percent_no_limit>` - Physical Used Percentage
  If this parameter is specified, the command displays information only about the aggregates that have the specified physical used percent.

- **-autobalance-state-change-counter** `<integer>` - State Change Counter for Auto Balancer (privilege: advanced)
  If this parameter is specified, the command displays information only about the aggregates that have the specified number of state change caused by the Auto Balance Aggregate feature.

- **-is-encrypted** `{true|false}` - Is Encrypted
  Selects the aggregates that are encrypted.

- **-snaplock-type** `-L (non-snaplock|compliance|enterprise)` - SnapLock Type
  If this parameter is specified, the command displays information only about the aggregates that have the specified snaplock-type.
[-encryption-key-id <text>] - Encryption Key ID
Selects the aggregates that are encrypted with the specified key ID.

[-is-cft-precommit {true|false}] - Is in the precommit phase of Copy-Free Transition (privilege: advanced)
Selects the aggregates that are set with this parameter value. This parameter lists all the aggregates that are in
the precommit phase of a Copy-Free Transition workflow.

[-is-transition-out-of-space {true|false}] - Is a 7-Mode transitioning aggregate that is not yet committed
in clustered Data ONTAP and is currently out of space (privilege: advanced)
Selects the aggregates that match this parameter value. This parameter is used to list all the 7-mode
transitioning aggregates that are not yet committed in clustered Data ONTAP and are currently out of space.

[-autobalance-unbalanced-threshold-percent <integer>] - Threshold When Aggregate Is Considered
Unbalanced (%) (privilege: advanced)
If this parameter is specified, the command displays information only about the aggregates that have the
specified unbalanced threshold percentage.

[-autobalance-available-threshold-percent <integer>] - Threshold When Aggregate Is Considered
Balanced (%) (privilege: advanced)
If this parameter is specified, the command displays information only about the aggregates that have the
specified available threshold percentage.

[-resync-priority {high(fixed)|high|medium|low}] - Resynchronization Priority
This parameter indicates the relative priority that is used to decide whether a mirrored aggregate can start a
resynchronization operation or not. This field is not set for unmirrored aggregates.
Use the storage aggregate resynchronization modify command to modify this field for mirrored
aggregates.
The valid values for this field are:
• high(fixed): This value is reserved for Data ONTAP system aggregates, which cannot have any other value
for this field. It cannot be explicitly set on a data aggregate. These aggregates always start their
resynchronization operation at the first available opportunity.
• high: Mirrored data aggregates with this priority value start resynchronization first.
• medium: Mirrored data aggregates with this priority value start resynchronization after all the system
aggregates and data aggregates with 'high' priority value have started resynchronization.
• low: Mirrored data aggregates with this priority value start resynchronization only after all the other
aggregates have started resynchronization.

[-data-compaction-space-saved {<integer>[KB|MB|GB|TB|PB]}] - Space Saved by Data Compaction
This parameter indicates the amount of the space saved by Data Compaction in bytes.

[-data-compaction-space-saved-percent <percent>] - Percentage Saved by Data Compaction
This parameter indicates the percentage of space saved in the aggregate by Data Compaction.

[-data-compacted-count {<integer>[KB|MB|GB|TB|PB]}] - Amount of compacted data
This parameter indicates the number of bytes occupied by compacted data inside this aggregate.

**Examples**
The following example displays information about all aggregates that are owned by nodes in the local cluster:

```
cluster1::> storage aggregate show

<table>
<thead>
<tr>
<th>Aggregate</th>
<th>Size Available</th>
<th>Used%</th>
<th>State</th>
<th>#Vols</th>
<th>Nodes</th>
<th>RAID Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>aggr0</td>
<td>6.21TB</td>
<td>1.78TB</td>
<td>71% online</td>
<td>49</td>
<td>cluster1-01</td>
<td>raid_dp</td>
</tr>
</tbody>
</table>
```

Storage aggregate Commands
The following example displays information about an aggregate name aggr1:

cluster1:/> storage aggregate show -aggregate aggr1

Aggregate: aggr1
Checksum Style: block
Number Of Disks: 6
Mirror: true
Nodes: cluster1-02
Disks for First Plex: 1.1.2,
1.1.10,
1.1.11
Disks for Mirrored Plex: 1.1.6,
1.1.8,
1.1.9
Free Space Reallocation: off
HA Policy: sfo
Space Reserved for Snapshot Copies: 5%
Hybrid Enabled: false
Available Size: 53.10MB
Block Type: 64-bit
Checksum Enabled: true
Checksum Status: active
Cluster: cluster1

**storage aggregate show-efficiency**

Display aggregate storage efficiency details

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.
Description

The storage aggregate show-efficiency command displays information about the storage efficiency of all the aggregates. The storage efficiency is displayed at four different levels:

- Total
- Aggregate
- Volume
- Snapshot and FlexClone volume

Parameters

{ [ -fields <fieldname>, ... ]
  If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

[ [-instance ]
  If you specify the -instance parameter, the command displays detailed information about all fields.

[ -aggregate <aggregate name> ] - Name of the Aggregate
  Displays the aggregate name. If this parameter is specified, the command displays detailed information about the storage efficiency of the specified aggregate.

[ -node { <nodename> | local } ] - Node where Aggregate Resides
  Displays the node which owns the aggregate. If this parameter is specified, the command displays storage efficiency information only about the aggregates that are located on the specified node.

[ -total-logical-used { <integer> [ KB | MB | GB | TB | PB ] } ] - Logical Size Used by Volumes, Clones, Snapshot Copies in the Aggregate
  Displays the logical size used in the aggregate. This includes Volumes, Clones and Snapshots in the aggregate. The logical size is computed based on physical usage and savings obtained in the aggregate.

[ -total-physical-used { <integer> [ KB | MB | GB | TB | PB ] } ] - Total Physical Used
  Displays the physical size used by the aggregate.

[ -total-storage-efficiency-ratio <text> ] - Total Storage Efficiency Ratio
  Displays the total storage efficiency ratio of the aggregate.

[ -volume-logical-used { <integer> [ KB | MB | GB | TB | PB ] } ] - Logical Space Used for All Volumes
  Displays the logical size used by all the volumes in the aggregate.

[ -volume-physical-used { <integer> [ KB | MB | GB | TB | PB ] } ] - Physical Space Used for All Volumes
  Displays the physical size used by all volumes in the aggregate.

  Displays the total disk space that is saved by deduplication and FlexClone for files or LUNs by all volumes in the aggregate.

[ -volume-compression-saved { <integer> [ KB | MB | GB | TB | PB ] } ] - Space Saved by Volume Compression
  Displays the total disk space that is saved by compressing blocks by all volumes in the aggregate.

  Displays the total disk space that is saved by inline zero pattern detection by all the volumes in the aggregate.

  Displays the storage efficiency ratio of all the volumes in the aggregate.

[ -aggr-logical-used { <integer> [ KB | MB | GB | TB | PB ] } ] - Logical Space Used by the Aggregate
  Displays the logical size used by the aggregate.
[-aggr-physical-used <integer> [KB|MB|GB|TB|PB]] - Physical Space Used by the Aggregate
Displays the physical size used by the aggregate.

[-aggr-compaction-saved <integer> [KB|MB|GB|TB|PB]] - Space Saved by Aggregate Compaction
Displays the total disk space that is saved by data compaction at the aggregate level.

[-aggr-data-reduction-storage-efficiency-ratio <text>] - Aggregate Data Reduction SE Ratio
Displays the storage efficiency ratio of the aggregate.

[-snapshot-logical-used <integer> [KB|MB|GB|TB|PB]] - Logical Size Used by Snapshot Copies
Displays the logical size used by all Volume Snapshots residing in the aggregate.

[-snapshot-physical-used <integer> [KB|MB|GB|TB|PB]] - Physical Size Used by Snapshot Copies
Displays the physical size used by all Volume Snapshots residing in the aggregate.

[-flexclone-volume-logical-used <integer> [KB|MB|GB|TB|PB]] - Logical Size Used by FlexClone Volumes
Displays the logical size used by all FlexClone volumes residing in the aggregate.

[-flexclone-volume-physical-used <integer> [KB|MB|GB|TB|PB]] - Physical Size Used by FlexClone Volumes
Displays the physical size used by all FlexClone volumes in the aggregate.

[-snapshot-flexclone-volume-data-reduction-storage-efficiency-ratio <text>] - Snapshot And FlexClone Volume Data Reduction SE Ratio
Displays the Snapshot and FlexClone volume storage efficiency ratio of the aggregate.

[-number-of-offline-volumes <integer>] - Number of Volumes Offline
Displays the number of volumes that are offline in the aggregate.

[-number-of-sis-disabled-volumes <integer>] - Number of SIS Disabled Volumes
Displays the number of volumes on which volume efficiency is disabled in the aggregate.

[-number-of-sis-change-log-disabled-volumes <integer>] - Number of SIS Change Log Disabled Volumes
Displays the number of volumes on which efficiency change log is disabled in the aggregate.

Examples
The following example displays information about all aggregates that are owned by nodes in the local cluster:

```
cluster1:*> storage aggregate show-efficiency
Aggregate: aggr1
Node: cluster1-01

----- Cumulative Storage Efficiency ------
Logical   Physical   Storage
Used      Used       Efficiency Ratio
----------- ----------- ------------------
25.74MB    11.80MB    2.18:1

--- Aggregate level Storage Efficiency ---
Logical   Physical   Compaction   Storage
Used      Used       Saved      Efficiency Ratio
----------- ----------- ----------- ------------------
15.72MB    11.80MB    3.93MB     1.33:1

--------------------- Volume level Storage Efficiency ------------------------
Logical   Physical   Efficiency Compression   VBN   Storage
Used      Used       Saved      Saved       Zero Saved   Efficiency Ratio
----------- ----------- ----------- ----------- ----------- ------------------
4.88MB     4.88MB     0B         0B         0B             1.00:1

--------------------- Snapshot and FlexClone volume Storage Efficiency --------
--------- Snapshot -------   --- FlexClone volume ----
Logical   Physical   Logical   Physical   Storage
Used      Used       Used      Used       Efficiency Ratio
----------- ----------- ----------- ----------- ------------------
```

Storage aggregate Commands
storage aggregate show-resync-status

Display aggregate resynchronization status

Availability: This command is available to *cluster* administrators at the *admin* privilege level.

Description

The `storage aggregate show-resync-status` command displays resync status information for each plex. The command output depends on the parameter or parameters specified with the command. If no parameters are specified, the command displays the following information about all aggregates:

- Aggregate Name
- Resyncing Plex Name
- Resyncing Percentage

Parameters

`[-fields <fieldname>, ...]`

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

`[-instance]`

If you specify the `-instance` parameter, the command displays detailed information about all fields.

`[-aggregate <aggregate name>]` - Aggregate

This parameter specifies the name of the aggregate.

`[-plex <text>]` - Plex Name

This parameter specifies the name of the plex.
[-status <text>] - Status
  Displays plex status. Possible values are:
  
  - normal
  - failed
  - empty
  - invalid
  - uninitialized
  - failed assimilation
  - limbo
  - active
  - inactive
  - resyncing

  These values may appear by themselves or in combination separated by commas; for example, "normal,active".

[-is-online {true|false}] - Is Online
  Indicates whether the plex is online.

[-in-progress {true|false}] - Resync is in Progress
  Indicates whether the plex is currently resyncing.

[-resyncing-percent <percent>] - Resyncing Percentage
  Displays the resynchronization completion percentage if the plex is currently being resynced, '-' otherwise.

[-resync-level <integer>] - Resync Level
  Displays the resync level if the plex is currently being resynced, '-' otherwise.

[-pool <integer>] - Pool
  The pool number to which the majority of disks in the plex belong.

Examples

The following example displays resynchronization status for all the aggregates:

```
cluster1::> storage aggregate show-resync-status

<table>
<thead>
<tr>
<th>Aggregate</th>
<th>Resyncing Plex</th>
<th>Percentage</th>
</tr>
</thead>
<tbody>
<tr>
<td>aggr0</td>
<td>plex0</td>
<td></td>
</tr>
<tr>
<td>aggr1</td>
<td>plex0</td>
<td></td>
</tr>
<tr>
<td>aggr1</td>
<td>plex1</td>
<td>10.00</td>
</tr>
<tr>
<td>aggr2</td>
<td>plex0</td>
<td></td>
</tr>
<tr>
<td>aggr2</td>
<td>plex2</td>
<td></td>
</tr>
</tbody>
</table>

5 entries were displayed.
```

storage aggregate plex show on page 711
storage aggregate show-scrub-status

Display aggregate scrubbing status

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The storage aggregate show-scrub-status command displays the following information about the scrub status of aggregates:

- Aggregate name
- RAID groups
- Whether the scrub is suspended
- Percentage of the scrub that is completed
- Last scrub time of the aggregate

Parameters

[-fields <fieldname>, ...]
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use -fields ? to display the fields to specify.

[-instance]]
If you specify the -instance parameter, the command displays detailed information about all fields.

[-aggregate <aggregate name>] - Aggregate
If this parameter is specified, the command displays detailed scrub-status information about the specified aggregate.

[-raidgroup <text>] - RAID Group
If this parameter is specified, the command displays information only about the aggregate that contains the specified RAID group.

[-node {<nodename>|local}] - Node
If this parameter is specified, the command displays information only about the aggregates on the specified node. The value local specifies the current node.

[-suspended {true|false}] - Is Suspended
If this parameter is specified, the command displays information only about the aggregates that have the specified scrub-suspension state (true or false).

[-complete-percentage <percent>] - Percentage Completed
If this parameter is specified, the command displays information only about the aggregates whose scrubs have the specified completed percentage.

[-last-scrub-time <MM/DD/YYYY HH:MM:SS>] - Last Scrub Time
If this parameter is specified, the command displays information only about the aggregates that have the specified last-scrub time, in the format MM/DD/YYYY HH:MM:SS.

Examples

The following example displays scrub-status information for all the aggregates:

```
cluster1::> storage aggregate show-scrub-status
Aggregate RAID Groups Suspended Percentage Last Scrub Time
----------------- -------------- ------------- --------------- --------------
aggr0 /aggr0/plex0/rg0 true 0% 3/31/2011 21:23:02
```
The following example displays detailed information about the aggregate named aggr1:

```
cluster1::> storage aggregate show-scrub-status -instance -aggregate aggr1
```

Aggregate: aggr1
RAID Group: /aggr1/plex0/rg0
Is Suspended: false
Percentage Completed: 2%
Last Scrub Time: 3/31/2011 22:02:50

### storage aggregate show-space

Display details of space utilization within an aggregate.

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**

The *storage aggregate show-space* command displays information about space utilization within aggregates. The command output breaks down space usage in the specified aggregate by feature. If no parameters are specified, the command displays this information about all aggregates:

**Parameters**

```
[-fields <fieldname>, ...]
```

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

```
[-instance]
```

If you specify the `-instance` parameter, the command displays detailed information about all fields.

```
[-aggregate <text>] - Aggregate Name
```

If this parameter is specified, the command displays information only about space used in the specified aggregate or aggregates.

```
[-volume-footprints {<integer>[KB|MB|GB|TB|PB]}] - Volume Footprints
```

If this parameter is specified, the command displays information only about the aggregate or aggregates that have the specified amount of space in use by volume footprints. A volume's footprint is the overall amount of space that a volume occupies in the aggregate, including the volume metadata and data.

```
[-volume-footprints-percent <percent_no_limit>] - Volume Footprints Percent
```

If this parameter is specified, the command displays information only about the aggregate or aggregates whose volume footprints occupy the specified percentage of space.

```
[-snap-size-total {<integer>[KB|MB|GB|TB|PB]}] - Total Space for Snapshot Copies in Bytes
```

If this parameter is specified, the command displays information only about the aggregate or aggregates that have the specified amount of space in use by aggregate Snapshot copies. This field includes the space that is reserved for Snapshot copies and is not available to volumes or aggregate data and metadata. It is set to 0 by default.

```
[-percent-snapshot-space <percent>] - Space Reserved for Snapshot Copies
```

If this parameter is specified, the command displays information only about the aggregate or aggregates that have the specified percentage of space in use by aggregate Snapshot copies.
[-aggregate-metadata \{<integer> [KB|MB|GB|TB|PB]\}] - Aggregate Metadata

If this parameter is specified, the command displays information only about the aggregate or aggregates that have the specified amount of space in use by aggregate metadata.

[-aggregate-metadata-percent <percent_no_limit>] - Aggregate Metadata Percent

If this parameter is specified, the command displays information only about the aggregate or aggregates that have the specified percentage of space in use by aggregate metadata.

[-used-including-snapshot-reserve \{<integer> [KB|MB|GB|TB|PB]\}] - Total Used

If this parameter is specified, the command displays information only about the aggregate or aggregates that have the specified amount of space in use in the aggregate.

It is important to note that this parameter treats the entire Snapshot reserve as used space since it is not available for volumes.

[-used-including-snapshot-reserve-percent <percent_no_limit>] - Total Used Percent

If this parameter is specified, the command displays information only about the aggregate or aggregates that have the specified percentage of space in use in the aggregate and its Snapshot reserve.

[-aggregate-size \{<integer> [KB|MB|GB|TB|PB]\}] - Size

If this parameter is specified, the command displays information only about the aggregate or aggregates that have the specified size.

[-snapshot-reserve-unusable \{<integer> [KB|MB|GB|TB|PB]\}] - Snapshot Reserve Unusable

If this parameter is specified, the command displays information only about the aggregate or aggregates that have the specified amount of space reserved but unusable in the volume.

Snapshot reserve can be diminished under certain conditions to accommodate volume metadata. Creating space in the aggregate will make this space available.

[-snapshot-reserve-unusable-percent <percent_no_limit>] - Snapshot Reserve Unusable Percent

If this parameter is specified, the command displays information only about the aggregate or aggregates that have the specified percentage of space reserved but unusable.

[-physical-used \{<integer> [KB|MB|GB|TB|PB]\}] - Total Physical Used Size

If this parameter is specified, the command displays information only about the aggregate or aggregates that have the specified amount of physical space in use by the aggregate.

This differs from total-used space by the space that is guaranteed for future writes. The value includes blocks in use by Snapshot copies.

[-physical-used-percent <percent_no_limit>] - Physical Used Percentage

If this parameter is specified, the command displays information only about the aggregate or aggregates that have the specified percentage of physical space in use in the aggregates.

### Examples

The following example displays information about all aggregates:

```bash
cluster1::> storage aggregate show-space
Aggregate : aggr0

<table>
<thead>
<tr>
<th>Feature</th>
<th>Used</th>
<th>Used%</th>
</tr>
</thead>
<tbody>
<tr>
<td>Volume Footprints</td>
<td>5.75GB</td>
<td>91%</td>
</tr>
<tr>
<td>Aggregate Metadata</td>
<td>380KB</td>
<td>0%</td>
</tr>
<tr>
<td>Snapshot Reserve</td>
<td>325.3MB</td>
<td>5%</td>
</tr>
<tr>
<td>Total Used</td>
<td>6.07GB</td>
<td>96%</td>
</tr>
<tr>
<td>Total Physical Used</td>
<td>221.9MB</td>
<td>3%</td>
</tr>
</tbody>
</table>
```

696 Commands: Manual Page Reference
storage aggregate show-spare-disks

Display spare disks

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The command storage aggregate show-spare-disks displays information about spare disks. The command output depends on the parameter or parameters specified with the command. If no parameters are specified, the command displays information about all spare disks in the cluster.

Parameters

[[-fields <fieldname>, ...]]

If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

| [-partition-info | (privilege: advanced)]

Displays the following information about root-data and root-data1-data2 partitioned spares.

- Disk
- Type
- Class
- RPM
- Checksum
- Local Data Usable
- Local Data1 Usable
- Local Data2 Usable
- Local Root Usable
- Physical Size
- Status

|[ -instance ]|

If this parameter is specified, the command displays detailed information about each spare disk.

[-original-owner <text>] - Original Owner

Selects the spare disks that match this parameter value.
[-disk <disk path name>] - Disk Name
Selects the spare disks that match this parameter value.

[-checksum-style {advanced_zoned | block | none}] - Checksum Style
Selects the spare disks that match this parameter value. Possible values are:
- block -- Supports block checksum
- advanced_zoned -- Supports advanced zone checksum
- none -- No checksum support

[-disk-type {ATA | BSAS | FCAL | FSAS | LUN | MSATA | SAS | SSD | VMDISK}] - Disk Type
Selects the spare disks that match this parameter value.

[-effective-disk-type {ATA | BSAS | FCAL | FSAS | LUN | MSATA | SAS | SSD | VMDISK}] - Effective Disk Type
Selects the spare disks that match this parameter value.
Hard disk drives with the same effective-disk-type value may be mixed together in the same aggregate depending upon the system's raid.mix.hdd.disktype.capacity and raid.mix.hdd.disktype.performance option settings.

[-disk-class {capacity | performance | archive | solid-state | array | virtual}] - Disk Class
Selects the spare disks that match this parameter value. Possible values are:
- capacity -- Capacity-oriented, near-line disk types. Includes disk types FSAS, BSAS and ATA.
- performance -- Performance-oriented, enterprise class disk types. Includes disk types FCAL and SAS.
- archive -- Archive class SATA disks in multi-disk carrier storage shelves. Includes disk type MSATA.
- solid-state -- Solid-state drives. Includes disk type SSD.
- array -- Logical storage devices backed by storage arrays and used by Data ONTAP as disks. Includes disk type LUN.
- virtual -- Virtual disks that are formatted and managed by VMware ESX. Includes disk type VMDISK.
Disks with the same disk-class value are compatible for use in the same aggregate.

[-disk-rpm <integer>] - Disk RPM
Selects the spare disks that match this parameter value.

[-effective-disk-rpm <integer>] - Effective Disk RPM
Selects the spare disks that match this parameter value.
Hard disk drives with the same effective-disk-rpm value may be mixed together in the same aggregate depending upon the system's raid.mix.hdd.rpm.capacity and raid.mix.hdd.rpm.performance option settings.

[-syncmirror-pool <text>] - Pool Number
Selects the spare disks that match this parameter value.

[-owner-name {<nodename> | local}] - Current Owner
Selects the spare disks that match this parameter value.

[-home-owner-name {<nodename> | local}] - Home Owner
Selects the spare disks that match this parameter value.

[-dr-owner-name {<nodename> | local}] - DR Home Owner
Selects the spare disks that match this parameter value.
[-usable-size-blks <integer>] - Disk Usable Size in 4K blocks
Selects the spare disks that match this parameter value.

[-local-usable-data-size-blks <integer>] - Local Node Data Usable Size in 4K blocks
Selects the spare disks that match this parameter value.
Disks that have two partitions can be used for one root aggregate and one data aggregate.
Disks that have three partitions can be used for one root aggregate and one or two data aggregates.
This value describes the data partition size (of root-data partitioned disk) or the combined data1 + data2 partition size (of root-data1-data2 partitioned disk) in 4KB blocks.

[-local-usable-root-size-blks <integer>] - Local Node Root Usable Size in 4K blocks
Selects the spare disks that match this parameter value.
Disks that have two partitions can be used for one root aggregate and one data aggregate.
Disks that have three partitions can be used for one root aggregate and one or two data aggregates.
This value describes the root partition size in 4KB blocks.

[-usable-size {<integer>[KB|MB|GB|TB|PB]}] - Disk Usable Size
Selects the spare disks that match this parameter value.

[-total-size {<integer>[KB|MB|GB|TB|PB]}] - Total Size
Selects the spare disks that match this parameter value.

[-local-usable-data-size {<integer>[KB|MB|GB|TB|PB]}] - Local Node Data Usable Size
Selects the spare disks that match this parameter value.
Disks that have two partitions can be used for one root aggregate and one data aggregate.
Disks that have three partitions can be used for one root aggregate and one or two data aggregates.
This value describes the data partition size (of root-data partitioned disk) or the combined data1 + data2 partition size (of root-data1-data2 partitioned disk) in auto-scaled units.

[-local-usable-root-size {<integer>[KB|MB|GB|TB|PB]}] - Local Node Root Usable Size
Selects the spare disks that match this parameter value.
Disks that have two partitions can be used for one root aggregate and one data aggregate.
Disks that have three partitions can be used for one root aggregate and one or two data aggregates.
This value describes the root partition size in auto-scaled units.

[-is-disk-zeroed {true|false}] - Is Disk Zeroed?
Selects the spare disks that match this parameter value.
When disks are zeroed, they can be provisioned directly into aggregates which avoids a lengthy zeroing process.

[-is-disk-zeroing {true|false}] - Is Disk Zeroing?
Selects the spare disks that match this parameter value.

[-zeroing-percent <percent>] - Zeroing Percentage Completed
Selects the spare disks that match this parameter value.

[-is-sparecore {true|false}] - Sparecore Disk?
Selects the spare disks that match this parameter value.

[-sparecore-status <Spare core status>] - Sparecore Status
Selects the spare disks that match this parameter value.
[-sparecore-percent <percent>] - Sparecore Percentage Completed

Selects the spare disks that match this parameter value.

[-is-disk-shared (true|false)] - Is Disk Shared?

Selects the spare disks that match this parameter value.

Shared disks have partitions that allow them to be used in multiple aggregates and between nodes in an HA pair. When set to true, this parameter selects shared disks in which the root partition and/or the data partition is a spare. When set to false only spare disks without partitions are displayed. When this parameter is not used, all spare disks are displayed.

[-is-disk-offline (true|false)] - Is Disk Offline?

Selects the spare disks that match this parameter value.

Disk offline events are typically temporary events which allow Data ONTAP to perform background error recovery activity.

[-is-disk-sick (true|false)] - Is Disk Sick?

Selects the spare disks that match this parameter value.

A sick disk triggers Rapid RAID Recovery to copy data to a spare drive. At the end of the process the sick disk is marked as broken.

[-is-disk-left-behind (true|false)] - Is Disk Left Behind Spare?

Selects the spare disks that match this parameter value.

Disks are left behind if they are not responding during a giveback or switchback event.

[-local-usable-data1-size-blks <integer>] - Local Node Data1 Usable Size in 4K blocks (privilege: advanced)

Selects the spare disks that match this parameter value.

Disks that have two partitions can be used for one root aggregate and one data aggregate.

Disks that have three partitions can be used for one root aggregate and one or two data aggregates.

This value describes the data1 partition size of a root-data1-data2 partitioned disk in 4KB blocks.

[-local-usable-data2-size-blks <integer>] - Local Node Data2 Usable Size in 4K blocks (privilege: advanced)

Selects the spare disks that match this parameter value.

Disks that have two partitions can be used for one root aggregate and one data aggregate.

Disks that have three partitions can be used for one root aggregate and one or two data aggregates.

This value describes the data2 partition size of a root-data1-data2 partitioned disk in 4KB blocks.

[-local-usable-data1-size <integer>[KB|MB|GB|TB|PB]] - Local Node Data1 Usable Size (privilege: advanced)

Selects the spare disks that match this parameter value.

Disks that have two partitions can be used for one root aggregate and one data aggregate.

Disks that have three partitions can be used for one root aggregate and one or two data aggregates.

This value describes the data1 partition size of a root-data1-data2 partitioned disk in auto-scaled units.

[-local-usable-data2-size <integer>[KB|MB|GB|TB|PB]] - Local Node Data2 Usable Size (privilege: advanced)

Selects the spare disks that match this parameter value.

Disks that have two partitions can be used for one root aggregate and one data aggregate.

Disks that have three partitions can be used for one root aggregate and one or two data aggregates.
This value describes the data2 partition size of a root-data1-data2 partitioned disk in auto-scaled units.

### Examples
Display spare disks owned by node `node-b`.

```
cluster1::> storage aggregate show-spare-disks -owner-name node-b

Original Owner: node-b
Pool0
     Spare Pool
     
     | Disk   | Type | Class      | RPM | Checksum | Usable Physical |
     |--------|------|------------|-----|----------|-----------------|
     | 1.1.13 | BSAS | capacity   | 7200| block    | 827.7GB 828.0GB |
     | 1.1.15 | BSAS | capacity   | 7200| block    | 413.2GB 414.0GB |

Original Owner: node-b
Pool0
     Partitioned Spares
     
     | Disk   | Type | Class      | RPM | Checksum | Local Data | Local Root Physical |
     |--------|------|------------|-----|----------|------------|---------------------|
     | 1.0.8  | SAS  | performance| 10000| block    | 472.9GB 73.89GB 547.1GB |
```

Check on the progress of a previous disk zeroing command.

```
cluster1::> storage aggregate show-spare-disks -owner-name node-b -zeroing-percent >0

Original Owner: node-b
Pool0
     Spare Pool
     
     | Disk   | Type | Class      | RPM | Checksum | Usable Physical |
     |--------|------|------------|-----|----------|-----------------|
     | 1.1.13 | BSAS | capacity   | 7200| block    | 827.7GB 828.0GB zeroing, 17% done |
     | 1.1.15 | BSAS | capacity   | 7200| block    | 413.2GB 414.0GB zeroing, 28% done |

2 entries were displayed.
```

### Storage aggregate show-status
Display aggregate configuration

**Availability:** This command is available to `cluster` administrators at the `admin` privilege level.

**Description**
The `storage aggregate show-status` command displays the RAID layout and disk configuration of aggregates. The command output depends on the parameter or parameters specified with the command. If no parameters are specified, the command displays information about all aggregates in the cluster.

**Note:** This command does not use pagination. You can reduce the output by filtering with the parameters below.
Parameters

{ [-fields <fieldname>, ...]

If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use -fields ? to display the fields to specify.

| [-instance ] |

This parameter currently has no effect.

[-aggregate <text>] - Aggregate Name

Selects the aggregates that match this parameter value.

[-node <nodename>] - Node

Selects the aggregates that match this parameter value.

[-aggregate-uuid <UUID>] - Aggregate UUID

Selects the aggregates that match this parameter value.

Examples

Display the RAID layout of a Flash Pool aggregate.

cluster1::> storage aggregate show-status -aggregate nodeB_flashpool_1

Owner Node: node-b
Aggregate: nodeB_flashpool_1 (online, raid_dp, hybrid) (block checksums)
Plex: /nodeB_flashpool_1/plex0 (online, normal, active, pool0)
RAID Group /nodeB_flashpool_1/plex0/rg0 (normal, block checksums)
<table>

storage aggregate verify

Verify an aggregate

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The storage aggregate verify command verifies the two plexes of an aggregate. It compares the data in the two plexes to ensure that the plexes are identical. It can be used whenever the administrator needs to ensure that the two plexes are completely synchronized with each other. To view any discrepancies, use the following command:

event log show -event raid.mirror.verify.mismatch
Parameters
- `aggregate <aggregate name>` - Aggregate
  This parameter specifies the aggregate to be verified. If no aggregate is specified then the action specified by the parameter `-action` will be taken on all the aggregates.

- `action {start|stop|resume|suspend|status}` - Action
  This parameter specifies the action to be taken. The possible actions are:
  - start - Starts a verify.
  - stop - Permanently stops a verify. A stopped verify cannot be resumed.
  - resume - Resumes a suspended verify.
  - suspend - Suspends a verify.
  - status - Displays the current status of a verify.

- `plex-to-fix <text>` - Plex to be Corrected in Case of Mismatches
  This parameter specifies the name of a plex to fix in case the two plexes of the aggregate do not match. The default behavior is to log any discrepancies instead of fixing them.

  Note: This parameter is only applicable when the command is used to start a verify.

Examples
The `storage aggregate verify` command verifies the two plexes of an aggregate. It compares the data in the two plexes to ensure that the plexes are identical. It can be used whenever the administrator needs to ensure that the two plexes are completely synchronized with each other. To view any discrepancies, use the following command:

```
  event log show -event raid.mirror.verify.mismatch
```

The following example starts a verify on an aggregate named aggr1.

```
  cluster1::> storage aggregate verify -aggregate aggr1 -action start
```

The following example queries the status of a verify on an aggregate named aggr1.

```
  cluster1::> storage aggregate verify -aggregate aggr1 -action status
  Aggregate:aggr1, Is Suspended:false, Percentage Completed:19.03%
```

The following example starts a verify on all the aggregates.

```
  cluster1::> storage aggregate verify -action start
```

storage aggregate inode-upgrade commands
Manage aggregate inode upgrade

storage aggregate inode-upgrade resume
Resume suspended inode upgrade

Availability: This command is available to `cluster` administrators at the `advanced` privilege level.
Description
The `storage aggregate inode-upgrade resume` command resumes a suspended inode upgrade process. The inode upgrade process might have been suspended earlier due to performance reasons.

Parameters
- `node (<nodename>|local)` - Node Name
  If this parameter is specified, the command resumes the upgrade process of an aggregate that is located on the specified node.
- `aggregate <aggregate name>` - Aggregate Name
  This specifies the aggregate for which the inode upgrade process is to be resumed.

Examples
The following example resumes an aggregate upgrade process:

```
cluster1::> storage aggregate inode-upgrade resume -aggregate aggr1
```

`storage aggregate inode-upgrade show`
Display inode upgrade progress

Availability: This command is available to `cluster` administrators at the `advanced` privilege level.

Description
The `storage aggregate inode-upgrade show` command displays information about aggregates undergoing the inode upgrade process. The command output depends on the parameter or parameters specified with the command. If no parameters are specified, the command displays the default fields about all aggregates undergoing the inode upgrade process. The default fields are:
- aggregate
- status
- scan-percent
- remaining-time
- space-needed
- scanner-progress

Parameters

```
[-fields <fieldname>, ...]
```
If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

```
[-instance]
```
If you specify the `-instance` parameter, the command displays detailed information about all fields.

```
[ -aggregate <text> ] - Aggregate Name
```
If this parameter is specified with the `-node` parameter, the command displays detailed information about the specified aggregate. If only this parameter is specified, the command displays information about all aggregates that match the specified name.
[--node <nodename>] - Node Name
   If this parameter is specified, the command displays information only about the aggregate or aggregates that are located on the specified node.

[--status {pending|scanning|suspended-initializing|suspended|cleanup-pending|cleanup|cleanup-done|suspended-aborting|suspended-removing|suspended-while-removing|suspended-ironing}] - Upgrade Status
   If this parameter is specified, the command displays information only about the aggregate or aggregates that match the specified inode upgrade status.

[--scan-percent <percent>] - Upgrade Scan Percent Complete
   If this parameter is specified, the command displays information only about the aggregate or aggregates that match the specified inode upgrade progress percentage.

[--space-needed {<integer>[KB|MB|GB|TB|PB]}] - Space Needed to Complete Upgrade
   If this parameter is specified, the command displays information only about the aggregate or aggregates where the space needed to complete the upgrade process matches the specified size.

[--remaining-time <[<integer>h][<integer>m][<integer>s]>] - Remaining Upgrade Time
   If this parameter is specified, the command displays information only about the aggregate or aggregates where the remaining time to complete the inode upgrade process matches the specified time.

[--scanner-progress <text>] - Scanner Progress
   If this parameter is specified, the command displays information only about the aggregate or aggregates where the progress of the inode upgrade process matches the input.

Examples
   The following example displays information about all aggregates undergoing the inode upgrade process:

```
cluster1::> storage aggregate inode-upgrade show
Aggregate Status    %Complete Time Remaining Space Needed Inode Progress
--------- --------- --------- -------------- ------------ --------------
aggr0     pending   0%        -              20.36MB      Public : Inode 0 out of 65562
aggr1     pending   0%        -              19.84MB      Public : Inode 0 out of 63714
```

Storage Aggregate Resynchronization Commands

Manage aggregate resynchronization priorities and options

The storage aggregate resynchronization command family manages the number and the order of aggregates that can start a resynchronization operation at any given time on a node. On SyncMirror enabled nodes, plexes of mirrored aggregates can go offline because of a variety of issues. When the disks of an offline plex come back online, we start a background resynchronization operation on the aggregate to make sure that the new plex is up to date again. These commands allow the user to control the number of resynchronization operations that can concurrently execute on a node, as well as the order in which the aggregates are picked for the resynchronization operation. On a node containing multiple data aggregates, the resynchronization of critical data aggregates can be prioritized by assigning a higher resync-priority value than the rest of the data aggregates.

The storage aggregate resynchronization options commands can be used to control the volume of background resynchronization I/O on a node after a storage or network outage by limiting the number of aggregates that can resynchronize at the same time on a node.

Related references
   storage aggregate resynchronization options on page 708
storage aggregate resynchronization modify

Modify aggregate resynchronization priorities

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The storage aggregate resynchronization modify command can be used to modify the resynchronization priority of an aggregate.

When the number of aggregates pending resynchronization is higher than the maximum number of concurrent resynchronization operations allowed on a node, the aggregates get resynchronized in the order of their “resync-priority” values.

For example, let the max-concurrent-resync under the storage aggregate resynchronization options directory for a node be set to two. If there are three aggregates waiting to be resynchronized, where their respective resync-priority values are high, medium, and low, then the third aggregate is not allowed to start resynchronization until one of the first two aggregates has completed resynchronizing.

Parameters

-aggregate <aggregate name> - Aggregate

This parameter specifies the aggregate that is to be modified.

[-resync-priority {high (fixed) | high | medium | low}] - Resynchronization Priority

This parameter specifies the new resynchronization priority value for the specified aggregate. This field cannot be modified for unmirrored or Data ONTAP system aggregates.

Possible values for this parameter are:

- high: Mirrored data aggregates with this priority value start resynchronization first.
- medium: Mirrored data aggregates with this priority value start resynchronization after all the system aggregates and data aggregates with 'high' priority value have started resynchronization.
- low: Mirrored data aggregates with this priority value start resynchronization only after all the other aggregates have started resynchronization.

Examples

The following example changes the resync-priority of a specified aggregate to medium:

```bash
cluster1:/> storage aggregate resynchronization modify -aggregate aggr1 -resync-priority medium
```

Related references

storage aggregate resynchronization options on page 708

storage aggregate resynchronization show

Display aggregate resynchronization priorities

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The storage aggregate resynchronization show command displays the relative resynchronization priority for each aggregate in the cluster. When a particular node restricts how many resync operations can be active concurrently, these priorities
are used to prioritize the operations. The maximum concurrent resync operations for a node is displayed in the storage aggregate resynchronization options show command. If no parameters are specified, the command displays the following information about all the aggregates in the cluster:

- Aggregate name
- Node that owns the aggregate
- Resync priority for the aggregate

**Parameters**

```bash
[[-fields <fieldname>, ...]]
```

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

```bash
[[-instance]]
```

If you specify the `-instance` parameter, the command displays detailed information about all fields.

```bash
[-aggregate <aggregate name>] - Aggregate
```

If this parameter is specified, the command displays the resynchronization priority only for the specified aggregate.

```bash
[-node {<nodename>|local}] - Node
```

If this parameter is specified, the command displays the resynchronization priority only for the aggregates owned by the specified node.

```bash
[-resync-priority {high(fixed)|high|medium|low}] - Resynchronization Priority
```

If this parameter is specified, the command displays only the resynchronization priority that matches the specified value. Possible values for this parameter are:

- **high(fixed)**: This value is reserved for Data ONTAP system aggregates, which cannot have any other value for this field. These aggregates always start their resynchronization operation at the first available opportunity. This value cannot be assigned to a data aggregate.
- **high**: Mirrored data aggregates with this priority value start resynchronization first.
- **medium**: Mirrored data aggregates with this priority value start resynchronization after all the system aggregates and data aggregates with 'high' priority value have started resynchronization.
- **low**: Mirrored data aggregates with this priority value start resynchronization only after all the other aggregates have started resynchronization.

When the number of aggregates waiting for resynchronization is higher than the maximum number of resynchronization operations allowed on a node, then the resync-priority field is used to determine which aggregate starts resynchronization first. This field is not set for unmirrored aggregates.

### Examples

The following command displays the resynchronization priorities for all the aggregates in the cluster:

```
cluster1::> storage aggregate resynchronization show
Aggregate Node       Resync Priority
----------------------- ---------------
aggr0_n1              cluster1-01      high(fixed)
aggr0_n2              cluster1-02      high(fixed)
aggr1                 cluster1-01      low
aggr2                 cluster1-01      high
```

Storage aggregate Commands

storage aggregate resynchronization options show on page 708

storage aggregate resynchronization options commands

The options directory

storage aggregate resynchronization options modify

Modify node specific aggregate resynchronization options

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The storage aggregate resynchronization options modify command can be used to modify the options that govern the resynchronization of aggregates on a given cluster node.

Modifying the max-concurrent-resyncs option changes the number of aggregates that are allowed to resynchronize concurrently. When the number of aggregates waiting for resynchronization is higher than this value, the aggregates are resynchronized in the order of their "resync-priority". This value can be modified using the storage aggregate resynchronization modify command while specifying the -resync-priority parameter.

Parameters

-node {<nodename>|local} - Node

This parameter specifies the node for which the option is to be modified.

[-max-concurrent-resync <integer>] - Maximum Concurrent Resynchronizing Aggregates

This parameter specifies the new value for the maximum number of concurrent resync operations allowed on a node. This option must be specified along with the -node parameter. When a node has active resync operations, setting this parameter to a value that is lower than the number of currently resyncing aggregates will trigger a user confirmation.

Examples

The following example changes the maximum concurrent resync operations for the specified node to ten:

```bash
cluster1::> storage aggregate resynchronization options modify -node node1 -max-concurrent-resyncs 10
```

Related references

storage aggregate resynchronization modify on page 706

storage aggregate resynchronization options show

Display node specific aggregate resynchronization options

Availability: This command is available to cluster administrators at the admin privilege level.
**Description**
The `storage aggregate resynchronization options show` command displays all the options that govern the resynchronization of aggregates on a given cluster node. If no parameters are specified, the command displays the following information about all nodes:

- Node for which the information is being displayed
- Maximum number of concurrent resynchronizing aggregates allowed

**Parameters**

`{ [-fields <fieldname>, ...]}
If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

`[[-instance]]
If you specify the `-instance` parameter, the command displays detailed information about all fields.

`[-node <nodename>|local] - Node
If this parameter is specified, the command displays resynchronization options only for the specified node.

`[-max-concurrent-resync <integer>] - Maximum Concurrent Resynchronizing Aggregates
If this parameter is specified, the command displays only the resynchronization option that matches the specified value.

**Examples**
The following example displays the maximum number of concurrent resyncs allowed for each node in the cluster:

```
cluster1::> storage aggregate resynchronization options show
Node                     Maximum Concurrent Resynchronizing Aggregates
------------------------- ---------------------------------------------
cluster1-01               15
cluster1-02               4
2 entries were displayed.
```

The following example displays the maximum number of concurrent resyncs allowed for a specified node:

```
cluster1::> storage aggregate resynchronization options show -node node1
Node                     Maximum Concurrent Resynchronizing Aggregates
------------------------- ---------------------------------------------
cluster1-01               15
```

The following example displays all the nodes that allow more than five concurrent resync operations:

```
cluster1::> storage aggregate resynchronization options show -max-concurrent-resyncs >5
Node                     Maximum Concurrent Resynchronizing Aggregates
------------------------- ---------------------------------------------
cluster1-01               15
```

**storage aggregate plex commands**
Manage storage aggregate plexes
The plex directory contains commands that operate on a plex of an aggregate.
**storage aggregate plex delete**

Delete a plex

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**
The `storage aggregate plex delete` command deletes the specified plex. The aggregate specified with the `-aggregate` parameter will be unmirrored and contain the remaining plex. The disks in the deleted plex become spare disks.

**Parameters**
- `-aggregate <aggregate name>` - Aggregate
  Name of an existing aggregate which contains the plex specified with the `-plex` parameter.
- `-plex <text>` - Plex
  Name of a plex which belongs to the aggregate specified with the `-aggregate` parameter.

**Examples**
The following example deletes plex0 of aggregate aggr1:

```shell
cluster1::> storage aggregate plex delete -aggregate aggr1 -plex plex0
```

**storage aggregate plex offline**

Offline a plex

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**
The `storage aggregate plex offline` command takes the specified plex offline. The aggregate specified with the `-aggregate` parameter must be a mirrored aggregate and both plexes must be online. Prior to taking a plex offline, the system will flush all internally-buffered data associated with the plex and create a snapshot that is written out to both plexes. The snapshot allows for efficient resynchronization when the plex is subsequently brought back online.

**Parameters**
- `-aggregate <aggregate name>` - Aggregate
  Name of an existing aggregate which contains the plex specified with the `-plex` parameter.
- `-plex <text>` - Plex
  Name of a plex which belongs to the aggregate specified with the `-aggregate` parameter.

**Examples**
The following example takes plex0 of aggregate aggr1 offline:

```shell
cluster1::> storage aggregate plex offline -aggregate aggr1 -plex plex0
```

**storage aggregate plex online**

Online a plex

**Availability:** This command is available to cluster administrators at the admin privilege level.
Description
The `storage aggregate plex online` command brings the specified plex online. The aggregate specified with the `-aggregate` parameter must be an online mirrored aggregate. The system will initiate resynchronization of the plex as part of online processing.

Parameters
- `-aggregate <aggregate name>` - Aggregate
  Name of an existing aggregate which contains the plex specified with the `-plex` parameter.
- `-plex <text>` - Plex
  Name of a plex which belongs to the aggregate specified with the `-aggregate` parameter.

Examples
The following example brings plex0 of aggregate aggr1 online:

```
cluster1::> storage aggregate plex online -aggregate aggr1 -plex plex0
```

storage aggregate plex show
Show plex details

Availability: This command is available to `cluster` administrators at the `admin` privilege level.

Description
The `storage aggregate plex show` command displays information for the specified plex. By default, the command displays the following information about all plexes:

- Aggregate Name
- Plex Name
- Is Online
- Is Resyncing
- Resyncing Percentage
- Plex Status

To display detailed information about a single plex, use the `-aggregate` and `-plex` parameter.

Parameters

```
[{-fields <fieldname>, ...}
  If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.
| [{-instance}
  If you specify the `-instance` parameter, the command displays detailed information about all fields.
[-aggregate <aggregate name>] - Aggregate
  Name of an existing aggregate which contains the plex specified with the `-plex` parameter.
[-plex <text>] - Plex Name
  Name of a plex which belongs to the aggregate specified with the `-aggregate` parameter.
[-status <text>] - Status
  Displays plex status. Possible values are:
```
• normal
• failed
• empty
• invalid
• uninitialized
• failed assimilation
• limbo
• active
• inactive
• resyncing

These values may appear by themselves or in combination separated by commas, for example, "normal,active".

[-is-online {true|false}] - Is Online
Selects the plexes that match this parameter value.

[-in-progress {true|false}] - Resync is in Progress
Selects the plexes that match this parameter value.

[-resyncing-percent <percent>] - Resyncing Percentage
Selects the plexes that match this parameter value.

[-resync-level <integer>] - Resync Level
Selects the plexes that match this parameter value.

[-pool <integer>] - Pool
Selects the plexes that match this parameter value.

Examples
The following example displays information about all the plexes for all the aggregates:

```
cluster1::> storage aggregate plex show

Aggregate| Plex   | Is Online | Is Resyncing | Resyncing Percent | Status
----------|--------|-----------|--------------|-------------------|---------
aggr0     | plex0  | true      | false        |                   | normal,active
aggr1     | plex0  | true      | false        |                   | normal,active
aggr1     | plex1  | true      | false        |                   | normal,active
aggr2     | plex0  | true      | false        |                   | normal,active
aggr2     | plex2  | true      | false        |                   | normal,active
5 entries were displayed.
```

The following example displays information about plex1 of aggregate aggr1:

```
cluster1::> storage aggregate plex show -aggregate aggr1 -plex plex1

Aggregate: aggr1
Plex Name: plex1
Status: normal,active
Is Online: true
```
Resync is in Progress: false
Resyncing Percentage: 
Resync Level: 
Pool: 1

storage aggregate reallocation commands

Commands for optimizing freespace layout

storage aggregate reallocation quiesce

Quiesce reallocate job on aggregate

Availability: This command is available to cluster administrators at the admin privilege level.

Description
Temporarily stops any reallocation jobs that are in progress. When you use this command, the persistent state is saved. You can use the storage aggregate reallocation restart command to restart a job that is quiesced.

There is no limit to how long a job can remain in the quiesced (paused) state.

Parameters
- aggregate <aggregate name> - Aggregate Name
  Specifies the aggregate on which you want to temporarily pause the job.

Examples

cluster1::> storage aggregate reallocation quiesce
    -aggregate aggr0

Related references

storage aggregate reallocation restart on page 713

storage aggregate reallocation restart

Restart reallocate job on aggregate

Availability: This command is available to cluster administrators at the admin privilege level.

Description
Starts a reallocation job. Use this command to restart a quiesced (temporarily stopped) job or a scheduled scan that is idle for the aggregate.

Parameters
- aggregate <aggregate name> - Aggregate Name
  Specifies the aggregate on which you want to restart reallocation scans.

[-ignore-checkpoint | -i [true]] - Ignore Checkpoint
  Restarts the job at the beginning when set to true. If you use this command without specifying this parameter, its effective value is false and the job starts the scan at the point where it was stopped. If you specify this parameter without a value, it is set to true and the scan restarts at the beginning.
storage aggregate reallocation schedule

Modify schedule of reallocate job on aggregate

Availability: This command is available to cluster administrators at the admin privilege level.

Description
Schedules a reallocation scan for an existing reallocation job. If the reallocation job does not exist, use the storage aggregate reallocation start command to define a reallocation job.

You can delete an existing reallocation scan schedule. However, if you do this, the job's scan interval reverts to the schedule that was defined for it when the job was created with the storage aggregate reallocation start command.

Parameters
- aggregate <aggregate name> - Aggregate Name
  Specifies the aggregate on which you want to schedule reallocation jobs.

[-del | -d [true]] - Delete
  Deletes an existing reallocation schedule when set to true. If you use this command without specifying this parameter, its effective value is false and the reallocation schedule is not deleted. If you specify this parameter without a value, it is set to true and the reallocation schedule is deleted.

[-cron | -s <text>] - Cron Schedule
  Specifies the schedule with the following four fields in sequence. Use a space between field values. Enclose the values in double quotes.
  • minute is a value from 0 to 59.
  • hour is a value from 0 (midnight) to 23 (11:00 p.m.).
  • day of week is a value from 0 (Sunday) to 6 (Saturday).
  • day of month is a value from 1 to 31.

  Note: If you specify 31 as the value for the day of month, reallocation scans will not run in any months with fewer than 31 days.

  Use an asterisk "*" as a wildcard to indicate every value for that field. For example, an * in the day of month field means every day of the month. You cannot use the wildcard in the minute field.

  You can enter a number, a range, or a comma-separated list of values for a field.

Examples

  cluster1::> storage aggregate reallocation schedule -aggregate aggr0 -cron "0 23 6 *"

Related references

  storage aggregate reallocation start on page 716
storage aggregate reallocation show

Show reallocate job status for improving free space layout

Availability: This command is available to cluster administrators at the admin privilege level.

Description
Displays the status of a reallocation scan, including the state, schedule, aggregate and scan id. If you do not specify the id for a particular reallocation scan, the command displays information about all the existing reallocation scans.

Parameters

\[ [-fields <fieldname>, ...] \]
Displays the value of relevant field that you specify for the reallocation scans that are present.

\[ [-v ] \]
Specify this parameter to display the output in a verbose format.

\[ [-instance ] \]
Displays information about reallocation scans on aggregates in a list format.

\[ -id <integer>\] - Job ID
Specify this parameter to display the reallocation scan that matches the reallocation job ID that you specify.

\[ -aggregate <aggregate name>\] - Aggregate Name
Specify this parameter to display the reallocation scan that matches the aggregate that you specify.

\[ -description <text>\] - Job Description
Specify this parameter to display reallocation scans that match the text description that you specify.

\[ -state {Initial|Queued|Running|Waiting|Pausing|Paused|Quitting|Success|Failure|Reschedule|Error|Quit|Dead|Unknown|Restart|Dormant}\] - Job State
Specify this parameter to display reallocation jobs that match the state that you specify.

\[ -progress <text>\] - Execution Progress
Specify this parameter to list the running reallocation jobs whose progress indicator matches the text that you provide. For example, if you specify "Starting ..." as the text string for the progress option, then the system lists all the jobs that are starting.

\[ -schedule <job_schedule>\] - Schedule Name
Specify this parameter to display reallocation scans that match the schedule name that you specify. If you want a list of all job schedules, use the job schedule show command.

\[ -global-status <text>\] - Global State of Scans
Specify this parameter to indicate if reallocation scans are on or off globally. You must type either of the following text strings:

- "Reallocation scans are on"
- "Reallocation scans are off"

Examples

<table>
<thead>
<tr>
<th>Job ID</th>
<th>Aggregate</th>
<th>Schedule</th>
<th>State</th>
</tr>
</thead>
<tbody>
<tr>
<td>23</td>
<td>aggr0</td>
<td>reallocate_0 23 * 6</td>
<td>Queued</td>
</tr>
</tbody>
</table>

Storage aggregate Commands
storage aggregate reallocation start

Start reallocate job on aggregate

Availability: This command is available to cluster administrators at the admin privilege level.

Description
Begins a reallocation scan on a specified aggregate.

Before performing a reallocation scan, the reallocation job normally performs a check of the current layout optimization. If the current layout optimization is less than the threshold, then the system does not perform a reallocation on the aggregate.

You can define the reallocation scan job so that it runs at a specific interval, or you can use the storage aggregate reallocation schedule command to schedule reallocation jobs.

Parameters

-aggregate <aggregate name> - Aggregate Name
Specify this parameter to specify the target aggregate on which to start a reallocation scan.

{-interval | -i <text>} - Interval Schedule
Specified the schedule in a single string with four fields:

- minute is a value from 0 to 59.
- hour is a value from 0 (midnight) to 23 (11:00 p.m.).
- day of month is a value from 1 to 31.

Note: If you specify 31 as the value for the day of the month, reallocation scans will not run in any of the months with fewer than 31 days.

- day of the week is a value from 0 (Sunday) to 6 (Saturday).

Use an asterisk "*" as a wildcard to indicate every value for that field. For example, an * in the day of month field means every day of the month. You cannot use the wildcard in the minute field.

You can enter a number, a range, or a comma-separated list of values for a field.

| [-once | -o [true]] | Once
Specifies that the job runs once and then is automatically removed from the system when set to true. If you use this command without specifying this parameter, its effective value is false and the reallocation scan runs as scheduled. If you enter this parameter without a value, it is set to true and a reallocation scan runs once.

Examples

cluster1::> storage aggregate reallocation start -aggregate aggr0 -interval "0 23 * 6"
Description
Stops and deletes any reallocation scan running on the specified aggregate. This command stops and deletes in-progress, scheduled, and quiesced scans.

Parameters
-aggregate <aggregate name> - Aggregate Name
Specify this parameter to specify the target aggregate on which to stop and delete a reallocation scan.

Examples
cluster1::> storage aggregate reallocation stop -aggregate aggr0

Storage Aggregate Relocation Commands
Manage aggregate relocation
The storage aggregate relocation commands enable you to relocate aggregates from one node to another node in the same cluster that share storage.

storage aggregate relocation show
Display relocation status of an aggregate
Availability: This command is available to cluster administrators at the admin privilege level.

Description
The storage aggregate relocation show command displays status of aggregates which were relocated in the last instance of relocation operation.

Parameters

[-fields <fieldname>,...]
If you specify the -fields <fieldname>, ... parameter, the command only displays the fields that you specify.

[-instance]
If you specify the -instance parameter, the command displays detailed information about all entries.

[-node {<nodename>|local}] - Node
Selects aggregates from the specified source node.

[-aggregate <text>] - Aggregate Name
Selects the aggregates that match this parameter value.

[-relocation-status <text>] - Aggregates Relocation Status
Selects the aggregates whose relocation status matches this parameter value.

[-destination <text>] - Destination for Relocation
Selects the aggregates that are designated for relocation on the specified destination node.

Examples
The following example displays the relocation status of aggregates on all nodes in the cluster:

<table>
<thead>
<tr>
<th>Source</th>
<th>Aggregate</th>
<th>Destination</th>
<th>Relocation Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>node0</td>
<td>-</td>
<td>-</td>
<td>Not attempted yet</td>
</tr>
</tbody>
</table>
storage aggregate relocation start

Relocate aggregates to the specified destination

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The storage aggregate relocation start command initiates the relocation of the aggregates from one node to the other node in the same cluster.

Parameters
- **-node** (<nodename>|local) - Name of the Node that currently owns the aggregate
  This specifies the source node where the aggregates to be relocated reside.
- **-destination** (<nodename>|local) - Destination node
  This specifies the destination node where aggregates are to be relocated.
- **-aggregate-list** <aggregate name>, ... - List of Aggregates to be relocated
  This specifies the list of aggregate names to be relocated from source node to destination node.
- **-override-vetoes** {true|false} - Override Vetoes
  This specifies whether to override the veto checks for relocation operation. Initiating aggregate relocation with vetoes overridden will result in relocation proceeding even if the node detects outstanding issues that would make aggregate relocation dangerous or disruptive. The default value is false.
- **-relocate-to-higher-version** {true|false} - Relocate To Higher Version
  This specifies if the aggregates are to be relocated to a node which is running on a higher version of Data ONTAP than the source node. If an aggregate is relocated to this destination then that aggregate cannot be relocated back to the source node till the source is also upgraded to the same or higher Data ONTAP version. This option is not required if the destination node is running on higher minor version, but the same major version. The default value is false.
- **-override-destination-checks** {true|false} - Override Destination Checks
  This specifies if the relocation operation should override the check done on destination node. This option could be used to force a relocation of aggregates even if the destination has outstanding issues. Note that this could make the relocation dangerous or disruptive. The default value is false.
- **-ndo-controller-upgrade** {true|false} - Relocate Aggregates for NDO Controller Upgrade (privilege: advanced)
  This specifies if the relocation operation is being done as a part of non-disruptive controller upgrade process. Aggregate relocation will not change the home ownerships of the aggregates while relocating as part of controller upgrade. The default value is false.

Examples
The following example relocates aggregates name aggr1 and aggr2 from source node node0 to destination node node1:

```
cluster1::> storage aggregate relocation start -node node0 -destination node1 -aggregate-list aggr1, aggr2
```
storage array commands

The array directory

storage array modify

Make changes to an array’s profile.

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The storage array modify command lets the user change several array parameters.

Parameters

- **-name <text>** - Name
  Storage array name, either generated by Data ONTAP or assigned by the user.

- **-prefix <text>** - Prefix
  Abbreviation for the named array.

- **-vendor <text>** - Vendor
  Array manufacturer.

- **-model <text>** - Model
  Array model number.

- **-options <text>** - options
  Vendor specific array settings.

- **-max-queue-depth <integer>** - Target Port Queue Depth (privilege: advanced)
  The target port queue depth for all target ports on this array.

- **-lun-queue-depth <integer>** - LUN Queue Depth (privilege: advanced)
  The queue depth assigned to array LUNs from this array.

- **{-is-upgrade-pending {true|false}}** - Upgrade Pending (privilege: advanced)
  Set this parameter to true if the array requires additional Data ONTAP resilience for a pending firmware upgrade. Keep this parameter false during normal array operation. This value can not be set to true if -path-failover-time is greater than zero.

- **{-path-failover-time <integer>** - Path Failover Time (sec)
  The time delay (in secs) before switching the I/O path when the path is deleted. The maximum time delay is 30 sec. The default is 0. This value can not be greater than zero if -is-upgrade-pending is true.

- **{-all-path-fail-delay <integer>** - Extend All Path Failure Event (secs)
  Use this parameter to increase the delay before Data ONTAP declares an "all path failure" event for an array. Delaying the "all path failure" event allows Data ONTAP to suspend I/O operations for a longer period of time before declaring a data access disruption, allowing for I/O operations to resume if any path comes back online within the specified duration. A valid delay is any value between 30 and 90 seconds. A value of 0 will reset the delay, resulting in default actions being taken whenever an "all path failure" event is detected.

Examples

This command changes the model to FastT.
storage array remove

Remove a storage array record from the array profile database.

Availability: This command is available to *cluster* administrators at the *admin* privilege level.

Description
The `storage array remove` command discards array profile records for a particular storage array from the cluster database. Upon command completion, if a storage array is still connected to the cluster, the array profile record is re-created with default values.

Parameters
- `name <text>` - Name
  Name of the storage array you want to remove from the database.

Examples
```
cluster1::> storage array remove IBM_1722_1
```

storage array rename

Change the name of a storage array in the array profile database.

Availability: This command is available to *cluster* administrators at the *admin* privilege level.

Description
The `storage array rename` command permits substitution of the array profile name which Data ONTAP assigned during device discovery. By default, the name that Data ONTAP assigned to the storage array during discovery is shown in Data ONTAP displays and command output.

Parameters
- `name <text>` - Name
  Storage array name either generated by Data ONTAP or assigned by the user.
- `new-name <text>` - The new name to assign to this array profile. (28 chars max)
  New name to assign to the storage array.

Examples
```
cluster1::> storage array rename -name HITACHI_DF600F_1 -new-name MyArray
```

storage array show

Display information about SAN-attached storage arrays.

Availability: This command is available to *cluster* administrators at the *admin* privilege level.

Description
The `storage array show` command displays information about arrays visible to the cluster. If no parameters are specified, the command displays the following information about all storage arrays:
• Prefix
• Name
• Vendor
• Model
• Options

To display detailed information about a single array, use the `-name` parameter. The detailed view adds the following information:

• Serial Number
• Optimization Policy
• Affinity
• Errors
• Path Failover Time
• Extend All Path Failure Event

Parameters

`{-fields <fieldname>, ...}

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

`{-instance}

If you specify the `-instance` parameter, the command displays detailed information about all fields.

`{-name <text>}` - Name

Selects the arrays that match this parameter value.

`{-prefix <text>}` - Prefix

Abbreviation for the named array.

`{-vendor <text>}` - Vendor

Array manufacturer.

`{-model <text>}` - Model

Array model number.

`{-options <text>}` - options

Vendor specific array settings.

`{-serial-number <text>}` - Serial Number

Array product identifier.

`{-max-queue-depth <integer>}` - Target Port Queue Depth (privilege: advanced)

Selects the arrays that match this parameter value.

`{-lun-queue-depth <integer>}` - LUN Queue Depth (privilege: advanced)

Selects the arrays that match this parameter value.

`{-optimization-policy {iALUA|eALUA|symmetric|proprietary|mixed|unknown}}` - Optimization Policy

Selects the arrays that match this parameter value.

`{-affinity {none|aaa|ap|mixed|unknown}}` - Affinity

Selects the arrays that match this parameter value.
[-error-text <text>, ...] - Error Text
Selects the arrays that match this parameter value.

[-is-upgrade-pending {true|false}] - Upgrade Pending (privilege: advanced)
Selects the arrays that match this parameter value.

[-path-failover-time <integer>] - Path Failover Time (sec)
Use this parameter to list arrays that have path failover time set to the value you specify.

[-all-path-fail-delay <integer>] - Extend All Path Failure Event (secs)
Use this parameter to list arrays that have the all path failure event delay set to the value you specify.

Examples
The following example displays information about all arrays.

```
cluster1::> storage array show
Prefix                  Name   Vendor            Model Options
------ ---------------------------- -------- ---------------- ----------
HITACHI_DF600F_1     HITACHI           DF600F
IBM_1722_1      IBM             1722
2 entries were displayed.
```

The following example displays detailed information about a specific array:

```
cluster1::> storage array show -name HITACHI_DF600F_1
Name: HITACHI_DF600F_1
Prefix: abc
Vendor: HITACHI
Model: DF600F
options:
Serial Number: 4291000000000000
Optimization Policy: iALUA
Affinity: aaa
Error Text:
Path Failover Timeout (sec): 30
Extend All Path Failure Event (secs): 50
```

storage array config commands
The config directory

storage array config show
Display connectivity to back-end storage arrays.

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The storage array config show command displays information about how the storage arrays connect to the cluster, LUN groups, number of LUNS, and more. Use this command to validate the configuration and to assist in troubleshooting.

Parameters

[-fields <fieldname>, ...]
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

|[-switch]|
If you specify this parameter, switch port information is shown.
If you specify the `-instance` parameter, the command displays detailed information about all fields.

`-node {<nodename>|local}` - Controller Name

Selects the arrays that match this parameter value.

`-group <integer>` - LUN Group

Selects the arrays that match this parameter value. A LUN group is a set of LUNs that shares the same path set.

`-target-wwpn <text>` - Array Target Ports

Selects the arrays that match this parameter value (the World Wide Port Name of a storage array port).

`-initiator <text>` - Initiator

Selects the arrays that match this parameter value (the host bus adapter that the clustered node uses to connect to storage arrays).

`-array-name <array name>` - Array Name

Selects the arrays that match this parameter value.

`-target-side-switch-port <text>` - Target Side Switch Port

Selects the arrays that match this parameter value.

`-initiator-side-switch-port <text>` - Initiator Side Switch Port

Selects the arrays that match this parameter value.

`-lun-count <integer>` - Number of array LUNs

Selects the arrays that match this parameter value.

`-ownership {all|assigned|unassigned}` - Ownership

Selects the arrays that match this parameter value.

### Examples

```

```

storage array commands
storage array disk commands

The storage array disk directory

storage array disk paths commands

The paths directory

storage array disk paths show

Display a list of LUNs on the given array

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The storage array disk paths show command displays information about disks and array LUNs. Where it appears in the remainder of this document, “disk” may refer to either a disk or an array LUN. By default, the command displays the following information about all disks:

- Disk Unique Identifier
- Controller name
- Initiator Port
- LUN ID
- Failover optimization type
- The Use State of the LUN on this path
- Target Port
- TPGN
- Port speeds
- Kbytes/sec on Disk (Rolling Average)
- Number IOPS per second on disk (Rolling Average)

To display detailed information about a single disk, use the -disk parameter.

Parameters

{ [-fields <fieldname>, ...] }  

Displays the specified fields for all disks, in column style output.

| [-switch ]  | Displays the switch port information for all disks, in column style output.
[-instance]
     Displays detailed disk information. If no disk path name is specified, this parameter displays the same detailed
     information for all disks as does the -disk parameter. If a disk path name is specified, then this parameter
     displays the same detailed information for the specified disks as does the -disk parameter.

[-uid <text>] - Disk Unique Identifier
     Selects the disks whose unique id matches this parameter value. A disk unique identifier has the form:

[-disk <disk path name>] - Disk Name
     Displays detailed information about the specified disks.

[-array-name <array name>] - Array Name
     Selects information about the LUNs presented by the specified storage array.

[-diskpathnames <disk path name>, ...] - Path-Based Disk Names
     Selects information about disks that have all of the specified path names.

[-nodelist {<nodename>|local}, ...] - Controller name
     Selects information about disks that are visible to all of the specified nodes.

[-initiator <text>, ...] - Initiator Port
     Selects information about disks that are visible to the initiator specified. Disks that are not currently in use by
     that initiator are included.

[-lun <integer>, ...] - LUN ID
     Selects information about the specified LUNs.

[-target-wwpn <text>, ...] - Target Port
     Selects information about disks that are visible on target ports identified by their World Wide Port Name.

[-initiator-side-switch-port <text>, ...] - Initiator Side Switch Port
     Selects information about disks visible to an initiator that is connected to the specified switch port.

[-lun-path-use-state <text>, ...] - The Use State of the LUN on this path
     Selects information about LUNs reporting the specified in-use state.

[-tpgn <integer>, ...] - Target Port Group Number
     Selects information about disks that belong to the specified Target Port Group Number.

[-port-speed <text>, ...] - Port Speed
     Selects information about disks served by a Host Bus Adapter that is running at the specified port speed.

[-lun-io-kbps <integer>, ...] - Kbytes/sec on Disk (Rolling Average)
     Selects information about the LUNs that have reached the specified I/O throughput.

[-lun-iops <integer>, ...] - Number IOPS per second on disk (Rolling Average)
     Selects information about the LUNs that have reached the specified number of IOPs.

[-target-side-switch-port <text>, ...] - Target Side Switch Port
     Selects information about disks that are visible on target ports identified by the switch port to which they are
     connected.

[-target-port-access-state <text>, ...] - Failover optimization type
     Selects information about disks visible on target ports that have the specified access state.

[-initiator-io-kbps <integer>, ...] - Kbytes of I/O per second on Initiator (Rolling Average)
     Selects information about disks visible to an initiator that has executed I/O at the specified throughput.
[-initiator-iops <integer>, ...] - Number of IOPS on Initiator (Rolling Average)
Selects information about disks visible to an initiator that has executed the specified number of IOPs.

[-target-io-kbps <integer>, ...] - Kbytes of I/O per second to Target (Rolling Average)
Selects information about disks visible on target ports that have reached the specified I/O throughput.

[-target-iops <integer>, ...] - Number of IOPS to Target (Rolling Average)
Selects information about disks visible on target ports that have performed the specified number of IOPs.

[-path-link-errors <integer>, ...] - Link Error count on path
Selects information about disks with paths that have incurred the specified number of FC link errors.

[-path-io-kbps <integer>, ...] - Kbytes of I/O per second on Path (Rolling Average)
Selects information about disk with paths that have reached the specified I/O throughput.

[-path-iops <integer>, ...] - Number of IOPS on Path (Rolling Average)
Selects information about disks on those paths that have reached the specified number of IOPs.

[-path-quality <integer>, ...] - Percentage of weighted error threshold
Selects information about disks on paths that have incurred the specified number of errors. The value displayed is a measure of the health of a path expressed as a percentage of an error threshold. Once a path has reached or surpassed the error threshold, another path will be selected for I/O transfer, if there is one available.

[-path-lun-in-use-count <integer>, ...] - Number of LUNs in the in-use state on this path
Selects information about disks with paths that have the specified in-use-count.

[-initiator-lun-in-use-count <integer>, ...] - Number of LUNs in the in-use state on this initiator
Selects information about disks with a path through an initiator that has the specified in-use-count.

[-target-lun-in-use-count <integer>, ...] - Number of LUNs in the in-use state on this target
Selects information about disks with a path through a target port that has the specified in-use-count.

[-preferred-target-port {true|false}, ...] - Whether or not target port group is preferred
Selects information about disks that match the specified parameter value indicating whether the backing storage is ALUA (Asymmetric Logical Unit Access) capable and has specified the array target port on this path to be a preferred target port for I/O.

[-vmdisk-device-id <integer>, ...] - Virtual disk device ID
Selects information about disks that have the specified virtual disk device ID.

[-host-adapter <text>] - Primary Path Host Adapter
Selects information about disks that are currently using the specified Host Bus Adapter.

[-primary-port <text>] - Primary Path Disk Port
Selects information about disks that use the specified primary port.

[-secondary-name <disk path name>] - Secondary Path Name
Selects information about disks that use the specified secondary path name, for multipath configuration.

[-secondary-port <text>] - Secondary Path Disk Port
Selects information about disks that use the specified secondary port.

Examples
The following example displays information about all disks:

```
cluster1::> storage array disk paths show
Disk Name: 1.0.20
LUN  Link  Disk
I/O Controller Initiator ID Acc Use Target Port TPGN Speed (KB/s)
```
storage array port commands

The port directory

storage array port modify

Make changes to a target port record.

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The storage array port modify command lets the user change array target port parameters.
Parameters
- **-name <text> - Name**
  
  Selects the array ports that match this parameter value. The storage array name is either generated by Data ONTAP or assigned by the user.

- **-wwnn <text> - WWNN**
  
  Selects the array ports that match this parameter value.

- **-wwpn <text> - WWPN**
  
  Selects the array ports that match this parameter value.

- **[-max-queue-depth <integer>] - Target Port Queue Depth**
  
  The target port queue depth for this target port.

- **[-utilization-policy {normal|defer}] - Utilization Policy**
  
  The policy used in automatically adjusting the queue depth of the target port based on its utilization.

Examples
This command changes the maximum queue depth for this target port to 32.

```
cluster1::> storage array port modify -name HITACHI_DF600F_1 -wwnn 50060e80004291c0 -wwpn 50060e80004291c0 -max-queue-depth 32
```

storage array port remove

Remove a port record from an array profile.

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**
The *storage array port remove* command removes a port from the array database. You might want to remove ports that are no longer connected to the clustered node. Port information can change after hardware replacement, rezing, or similar configuration activities. The database retains the records about previous ports unless you remove the information.

**Parameters**
- **-name <text> - Name**
  
  Selects the array ports that match this parameter value. The storage array name is either generated by Data ONTAP or assigned by the user.

- **-wwnn <text> - WWNN**
  
  Selects the array ports that match this parameter value.

- **-wwpn <text> - WWPN**
  
  Selects the array ports that match this parameter value.

Examples
This command removes a port record from the array profiles database.

```
cluster1::> storage array port remove -name HITACHI_DF600F_1 -wwnn 50060e80004291c0 -wwpn 50060e80004291c0
```
storage array port show

Display information about a storage array's target ports.

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The storage array port show command displays all the target ports known to the cluster for a given storage array (if an array name is specified) or for all storage arrays if no storage array name is specified. Target ports remain in the database as part of an array profile unless you explicitly remove them from the database.

Parameters
{-fields <fieldname>, ...}
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

[-instance]]
If you specify the -instance parameter, the command displays detailed information about all fields.

[-name <text>] - Name
Selects the array ports that match this parameter value. The storage array name is either generated by Data ONTAP or assigned by the user.

[-wwnn <text>] - WWNN
Selects the array ports that match this parameter value.

[-wwpn <text>] - WWPN
Selects the array ports that match this parameter value.

[-max-queue-depth <integer>] - Target Port Queue Depth
Selects the array ports that match this parameter value.

[-node {<nodename>|local}, ...] - Controller Name
Selects the array ports that match this parameter value.

[-initiator-port <text>, ...] - Initiator Port
Selects the array ports that match this parameter value.

[-average-dynamic-queue-depth <integer>, ...] - Average Dynamic Queue Depth (privilege: advanced)
The average value of the dynamic target port queue depth.

[-average-latency-per-iop <integer>, ...] - Average Latency Per IOP
Selects the array ports that match this parameter value (average latency per I/O performed in microseconds).

[-average-pending <integer>, ...] - Average Pending (privilege: advanced)
Selects the array ports that match this parameter value (average over time of how many commands are on the outstanding queue).

[-average-waiting <integer>, ...] - Average Waiting (privilege: advanced)
Selects the array ports that match this parameter value (average over time of how many commands are on the waiting queue).

[-connection-type {direct|fabric}] - Connection Type
Selects the array ports that match this parameter value (type of connection between the controller and the back end storage).

[-dynamic-queue-depth <integer>, ...] - Dynamic Queue Depth (privilege: advanced)
Current dynamic target port queue depth, the maximum number of commands allowed outstanding.
- `max-pending <integer>, ...` - Max Pending (privilege: advanced)
  Selects the array ports that match this parameter value (largest number of commands observed on the outstanding queue).

- `max-waiting <integer>, ...` - Max Waiting (privilege: advanced)
  Selects the array ports that match this parameter value (largest number of commands observed on the waiting queue).

- `path-link-errors <integer>, ...` - Link Error count on path
  Selects the array ports that match this parameter value.

- `percent-busy <integer>, ...` - Percent Busy
  Selects the array ports that match this parameter value (percentage of time I/Os are outstanding on the port).

- `percent-waiting <integer>, ...` - Percent Waiting
  Selects the array ports that match this parameter value (percentage of time there are I/Os waiting on the throttle list on the target port).

- `switch-port <text>` - Switch Port
  Selects the array ports that match this parameter value (for fabric attached connections, the switch port the array target port is connected to; N/A for direct attached).

- `target-io-kbps <integer>, ...` - Kbytes of I/O per second to Target (Rolling Average)
  Selects the array ports that match this parameter value.

- `target-iops <integer>, ...` - Number of IOPS to Target (Rolling Average)
  Selects the array ports that match this parameter value.

- `target-lun-in-use-count <integer>, ...` - Target LUN In Use Count
  Selects the array ports that match this parameter value (number of IN-USE disks on this target port).

- `target-port-speed <text>` - Target Port Speed
  Selects the array ports that match this parameter value (speed that the target port has negotiated with its connected switch port, or initiator port if direct attached).

- `utilization-policy {normal|defer}` - Utilization Policy
  The policy used when sending I/O to an array target port when it reaches maximum queue depth. Possible values are:
  - normal - This policy aggressively competes for target port resources, in effect competing with other hosts. (default)
  - defer - This policy does not aggressively compete for target port resources, in effect deferring to other hosts.

### Examples

The example below displays the port information for a single port.

```
cluster1::> storage array port show -wwpn 50060e80004291c0
Array Name: HITACHI_DF600F_1
WWNN: 50060e80004291c0
WWPN: 50060e80004291c0
Connection Type: fabric
Switch Port: vgbr300s89:9
Link Speed: 4 GB/s
Max Queue Depth: 1024
Utilization Policy: normal

Commands: Manual Page Reference
storage automated-working-set-analyzer commands

Manage Automated Working Set Analyser

storage automated-working-set-analyzer show

Display running instances

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
The automated-working-set-analyzer show command displays the Automated Working-set Analyzer running instances.

Parameters

{-fields <fieldname>,...}
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

[-instance]
If you specify the -instance parameter, the command displays detailed information about all fields.

[-node <nodename>] - Node Name
This parameter indicates the node name that the AWA instance runs on.

[-flash-cache {true|false}] - Flash Cache Node-wide Modeling
This parameter indicates whether the AWA is modeling flash-cache.

[-aggregate-uuid <UUID>] - Uuid of the Aggregate
This parameter indicates the aggregate uuid that the AWA instance runs on.

[-aggregate <aggregate name>] - Aggregate
This parameter indicates the aggregate name that the AWA instance runs on.

[-working-set-size {true|false}] - Working Set Size
This parameter indicates whether the AWA instance is configured to find the working set size.

[-start-time <Date>] - Starting Time
This parameter indicates the time when the AWA instance was started.

[-total-intervals <integer>] - Total Interval Count
This parameter indicates the total number of intervals that the AWA instance has covered.

[-read-throughput (<integer> [Bps|KBps|MBps|GBps])] - Read Throughput
This parameter indicates the maximum read throughput over an interval that AWA has observed from the storage disks.

[-write-throughput (<integer> [Bps|KBps|MBps|GBps])] - Write Throughput
This parameter indicates the maximum write throughput over an interval that AWA has observed to the storage disks.
[-cacheable-read <percent>] - Cacheable Read
This parameter indicates the maximum percent of cacheable read over an interval that AWA has observed. Cacheable reads are non-sequential reads, i.e., the percentage of data reads that could have been cached.

[-cacheable-write <percent>] - Cacheable Write
This parameter indicates the maximum percent of cacheable write over an interval that AWA has observed. Cacheable writes are random overwrites, percentage of disk writes that could have been cached.

[-projected-cache-size <integer> [KB|MB|GB|TB|PB]] - Max Projected Cache Size
This parameter indicates the projected Flash Pool cache usage.

[-projected-read-hit <percent>] - Projected Read Hit
This parameter indicates the percentage of blocks that could be read from the Flash Pool cache instead of HDDs.

[-projected-write-hit <percent>] - Projected Write Hit
This parameter indicates the percentage of block overwrites that could go to the Flash Pool cache instead of HDDs.

[-referenced-interval-id <integer>] - Referenced Interval ID
This parameter indicates the interval in which the cache size effect information is derived from.

[-referenced-interval-time <Date>] - Referenced Interval Time
This parameter indicates the time when the referenced interval for the cache size effect information is derived from.

[-referenced-interval-cache-size <integer> [KB|MB|GB|TB|PB]] - Referenced Interval Cache Size
This parameter indicates the cache size at the end of the referenced interval from which the cache size effect information is based on.

[-read-hit-20 <percent>] - 20% Cache Read Hit
This parameter indicates the predicted read hit rate when the cache size is 20% of the referenced cache size.

[-read-hit-40 <percent>] - 40% Cache Read Hit
This parameter indicates the predicted read hit rate when the cache size is 40% of the referenced cache size.

[-read-hit-60 <percent>] - 60% Cache Read Hit
This parameter indicates the predicted read hit rate when the cache size is 60% of the referenced cache size.

[-read-hit-80 <percent>] - 80% Cache Read Hit
This parameter indicates the predicted read hit rate when the cache size is 80% of the referenced cache size.

[-read-hit-100 <percent>] - 100% Cache Read Hit
This parameter indicates the predicted read hit rate when the cache size is 100% of the referenced cache size.

[-write-hit-20 <percent>] - 20% Cache Write Hit
This parameter indicates the predicted write hit rate when the cache size is 20% of the referenced cache size.

[-write-hit-40 <percent>] - 40% Cache Write Hit
This parameter indicates the predicted write hit rate when the cache size is 40% of the referenced cache size.

[-write-hit-60 <percent>] - 60% Cache Write Hit
This parameter indicates the predicted write hit rate when the cache size is 60% of the referenced cache size.

[-write-hit-80 <percent>] - 80% Cache Write Hit
This parameter indicates the predicted write hit rate when the cache size is 80% of the referenced cache size.

[-write-hit-100 <percent>] - 100% Cache Write Hit
This parameter indicates the predicted write hit rate when the cache size is 100% of the referenced cache size.
Examples
The following example shows a running instance of automated-working-set-analyzer on node node1 for aggregate aggr0.

```
cluster1::> cluster-1::*> storage automated-working-set-analyzer show
Node   FC  Aggregate   wss  Intervals      Start Time
node1  false aggr0  false        125 Wed Jul 22 13:58:17 2015
```

**storage automated-working-set-analyzer start**

Command to start Automated Working Set Analyzer on node or aggregate

**Availability:** This command is available to cluster administrators at the *advanced* privilege level.

**Description**
The automated-working-set-analyzer start command enables the Automated Workload Analyzer that is capable of doing the following:

- Flash Pool modeling for an aggregate
- Flash Cache modeling for a node - can not specify an aggregate.
- Working set size estimation
- Workload monitoring

**Parameters**

- `-node <nodename>` - Node Name
  This parameter indicates the node name that the AWA instance runs on.

- `[-flash-cache [true|false]]` - Flash Cache Node-wide Modeling
  This parameter indicates whether the AWA is modeling flash-cache.

- `[-aggregate <aggregate name>]` - Aggregate
  This parameter indicates the aggregate name that the AWA instance runs on.

- `[-working-set-size [true|false]]` - Working Set Size
  This parameter indicates whether the AWA instance is configured to find the working set size.

**Examples**

```
cluster1::> storage automated-working-set-analyzer start -node vsim1 -aggregate aggr0
```

**storage automated-working-set-analyzer stop**

Command to stop Automated Working Set Analyzer on node or aggregate

**Availability:** This command is available to cluster administrators at the *advanced* privilege level.

**Description**
The storage automated-working-set-analyzer stop command terminates one or multiple Automated Workload Analyzer running instances.

storage automated-working-set-analyzer commands 733
Parameters

- **node <nodename>** - Node Name
  This parameter indicates the node name that the AWA instance runs on.

  - **flash-cache {true|false}** - Flash cache node-wide modeling
    This parameter indicates whether the AWA is modeling flash-cache.

  - **aggregate <aggregate name>** - Aggregate
    This parameter indicates the aggregate name that the AWA instance runs on.

Examples

```
cluster1::> storage automated-working-set-analyzer stop -node vsim1 -aggregate aggr1
```

storage automated-working-set-analyzer volume commands

The volume directory

storage automated-working-set-analyzer volume show

Displays the Automated Working Set Analyzer volume table

**Availability:** This command is available to cluster administrators at the advanced privilege level.

**Description**
The automated-working-set-analyzer volume show command displays the volume statistics reported by the corresponding Automated Working-set Analyzer running instances.

**Parameters**

- **fields <fieldname>, ...**
  If you specify the `fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `fields ?` to display the fields to specify.

- **instance**
  If you specify the `instance` parameter, the command displays detailed information about all fields.

- **node <nodename>** - Node
  This parameter indicates the node name that the AWA instance runs on.

- **flash-cache {true|false}** - Flash Cache Node-wide Modeling
  This parameter indicates whether the AWA is modeling flash-cache.

- **vol-uuid <UUID>** - Uuid of the Volume
  This parameter indicates the volume uuid that this command is issued on.

- **aggregate <aggregate name>** - Aggregate
  This parameter indicates the aggregate name that the AWA instance runs on.

- **volume <volume name>** - Volume
  This parameter indicates the volume name that this command is issued on.

- **rank <integer>** - Cache Benefit Rank
  This parameter indicates the rank of this volume among all volumes that would be most benefited by the modeled cache technology based on the AWA prediction.
[-read-throughput {<integer>[Bps|KBps|MBps|GBps]}] - Read Throughput
This parameter indicates the maximum read throughput over an interval that AWA has observed from the storage disks for this volume.

[-write-throughput {<integer>[Bps|KBps|MBps|GBps]}] - Write Throughput
This parameter indicates the maximum write throughput over an interval that AWA has observed to the storage disks for this volume.

[-cacheable-read <percent>]] - Cacheable Read
This parameter indicates the maximum percent of cacheable read over an interval that AWA has observed for this volume. Cacheable reads are non-sequential reads, i.e., the percentage of data reads that could have been cached.

[-cacheable-write <percent>] - Cacheable Write
This parameter indicates the maximum percent of cacheable write over an interval that AWA has observed. Cacheable writes are random overwrites, percentage of disk writes that could have been cached.

[-projected-cache-size {<integer>[KB|MB|GB|TB|PB]}] - Max Projected Cache Size
This parameter indicates the projected Flash Pool cache usage by this volume.

[-projected-read-hit <percent>] - Projected Read Hit
This parameter indicates the percentage of blocks that could be read from the Flash Pool cache instead of HDDs for this volume.

[-projected-write-hit <percent>] - Projected Write Hit
This parameter indicates the percentage of block overwrites that could go to the Flash Pool cache instead of HDDs for this volume.

Examples

cluster1::> cluster-1::*> storage automated-working-set-analyzer volume show
Node          FC    Aggregate    Volume       Rank  Read Thrupt Write Thrupt
------------- ----- ------------ ------------ ---- ------------ ------------
vsim1         false aggr0        vol0            1   230.47KBps   580.09KBps

storage bridge commands
Storage bridge monitoring commands

storage bridge add
Add a bridge for monitoring

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The storage bridge add command enables you to add FC-to-SAS bridges for SNMP monitoring in a MetroCluster configuration.

Parameters
- address <IP Address> - Bridge Management Port IP Address
  This parameter specifies the IP address of the bridge that is being added for monitoring.

[-snmp-community <text>] - SNMP Community
  This parameter specifies the SNMP community set on the bridge that is being added for monitoring.
[-veto-backend-fabric-check {true|false}] - Veto Backend Fabric Check (privilege: advanced)

If specified, the storage bridge add command will not check if the bridge is present in the MetroCluster's backend fabric. By default, it does not let you add bridges that are not present.

Examples
The following command adds a bridge with IP address '10.226.197.16' for monitoring:

```
cluster1::> storage bridge add -address 10.226.197.16
cluster1::> storage bridge show
```

<table>

storage bridge modify
Modify a bridge's configuration information

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The storage bridge modify enables you to modify certain parameters for identifying and accessing the FC-to-SAS bridges added for monitoring in a MetroCluster configuration.

Parameters
- **-name <text>** - Bridge Name
  This parameter specifies the name of the bridge.

[-address <IP Address>] - Bridge IP Address
This parameter specifies the IP address of the bridge.

[-snmp-community <text>] - SNMP Community Set on the Bridge
This parameter specifies the SNMP community set on the bridge.

Examples
The following command modifies 'ATTO_10.226.197.16' bridge SNMP community to 'public'.
storage bridge refresh

Refresh storage bridge info

Availability: This command is available to cluster administrators at the advanced privilege level.

Description

The storage bridge refresh command triggers a refresh of the SNMP data for the MetroCluster FC switches and FC-to-SAS bridges. It does not do anything if the refresh is already going on. The FC switches and FC-to-SAS bridges must have been previously added for monitoring by using the storage switch add and storage bridge add commands respectively.

Examples

The following command triggers a refresh for the SNMP data:

```
cluster1::*> storage bridge refresh
cluster1::*> 
```

storage bridge remove

Remove a bridge from monitoring

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The storage bridge remove enables you to remove FC-to-SAS bridges that were previously added for SNMP monitoring.

Parameters

-name <text> - Bridge Name

This parameter specifies the name of the bridge added for monitoring.

Examples

The following command removes 'ATTO_10.226.197.16' bridge from monitoring:

```
cluster1::> storage bridge remove -name ATTO_10.226.197.16
cluster1::> storage bridge show

storage bridge commands 737
storage bridge show

Display bridge information

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The storage bridge show command displays information about all the storage bridges in the MetroCluster configuration. The bridges must have been previously added for monitoring using the storage bridge add command. If no parameters are specified, the default command displays the following information about the storage bridges:

- Bridge
- Symbolic Name
- Vendor
- Model
- Bridge WWN
- Is Monitored
- Monitor Status

To display detailed profile information about a single storage bridge, use the -name parameter.

Parameters

[-fields <fieldname>, ...]

Displays the specified fields for all the storage bridges, in column style output.

[-connectivity]

Displays the following details about the connectivity from different entities to the storage bridge:

- Node
- Initiator
- Initiator Side Switch Port
- Target Side Switch Port
- Target Port WWN
- Target Port Number

[-cooling]

Displays the following details about the chassis temperature sensor(s) on the storage bridge:

- Sensor Name
• Reading in degree Celsius (C)
• Fan operational status
• Minimum Safe Operating Temperature in degree Celsius (C)
• Maximum Safe Operating Temperature in degree Celsius (C)
• Sensor Status

[-error]
Displays the errors related to the storage bridge.

[-ports]
Displays the following details about the storage bridge FC ports:
• Port number
• Port administrative status
• Port operational status
• Port operating mode
• Port negotiated speed
• Peer world wide name
Displays the following details about the storage bridge SAS ports:
• Port number
• Port negotiated data rate
• Port data rate capability
• Port PHY1 operational status
• Port PHY2 operational status
• Port PHY3 operational status
• Port PHY4 operational status
• Port administrative status
• Port operational status
• Peer world wide name

[-power]
Displays the status of the replaceable power supplies for the FibreBridge 7500 only:
• Power supply name
• Power supply status

[-sfp]
Displays the following details about the storage bridge FC ports Small Form-factor Pluggable (SFP):
• Port number
• SFP vendor
• SFP serial number
• SFP part number
• SFP speed capability
Displays the following details about the storage bridge SAS ports Quad Small Form-factor Pluggable (QSFP):
• Port number
• QSFP vendor
• QSFP serial number
• QSFP type
• QSFP part number
Displays the following details about the storage bridge SAS ports Mini-SAS HD:
• Port number
• Mini-SAS HD vendor
• Mini-SAS HD serial number
• Mini-SAS HD type
• Mini-SAS HD part number

| [-stats ]

Displays the following details about the storage bridge FC ports:
• Port number
• Port operational status
• Port operational mode
• Port negotiated speed
• Port link failure count
• Port synchronization loss count
• Port CRC error count
• Port operational mode
• Port received word count (Rx)
• Port transmitted word count (Tx)
Displays the following details about the storage bridge SAS ports:
• Port number
• PHY port number
• Port negotiated speed
• Port speed capability
• Port invalid DWORD count
• Port disparity error count
• Port synchronization loss count
- Port PHY reset count
- Port link changed count
- Port CRC error count

\([-\text{instance}]\)

Displays expanded information about all the storage bridges in the system. If a storage bridge is specified, then this parameter displays the same detailed information for the storage bridge you specify as does the -name parameter.

\[-\text{name <text>}\] - Bridge Name

Displays information only about the storage bridges that match the name you specify.

\[-\text{wwn <text>}\] - Bridge World Wide Name

Displays information only about the storage bridges that match the bridge wwn you specify.

\[-\text{model <text>}\] - Bridge Model

Displays information only about the storage bridges that match the bridge model you specify.

\[-\text{vendor \{unknown|Atto\}}\] - Bridge Vendor

Displays information only about the storage bridges that match the bridge vendor you specify.

\[-\text{fw-version <text>}\] - Bridge Firmware Version

Displays information only about the storage bridges that match the bridge firmware version you specify.

\[-\text{serial-number <text>}\] - Bridge Serial Number

Displays information only about the storage bridges that match the bridge serial number you specify.

\[-\text{address <IP Address>}\] - Bridge IP Address

Displays information only about the storage bridges that match the bridge IP address you specify.

\[-\text{is-monitoring-enabled \{true|false\}}\] - Is Monitoring Enabled for Bridge?

Displays information only about the storage bridges that match the bridge monitoring value you specify.

\[-\text{status \{unknown|ok|error\}}\] - Bridge Status

Displays information only about the storage bridges that match the bridge monitoring status you specify.

\[-\text{profile-data-last-successful-refresh-timestamp MM/DD/YYYY HH:MM:SS [+|-]hh:mm}\] - Bridge Profile Data Last Successful Refresh Timestamp

Displays information only about the storage bridges that match the profile data last successful refresh timestamp you specify.

\[-\text{symbolic-name <text>}\] - Bridge Symbolic Name

Displays information only about the storage bridges that match the symbolic name you specify.

\[-\text{snmp-community <text>}\] - SNMP Community Set on the Bridge

Displays information only about the storage bridges that match the bridge SNMP community you specify.

\[-\text{error-text-list <text>, ...}\] - Bridge Error Description List

Displays information only about the storage bridges that have the errors you specify.

\[-\text{temp-sensor-name <text>}\] - Temperature Sensor Name

Displays information only about the storage bridges that have the temperature sensor with the name you specify.

\[-\text{min-safe-oper-temp <integer>}\] - Minimum Safe Operating Temperature in Degree Celsius

Displays information only about the storage bridges that have the temperature sensor with the minimum safe operating temperature you specify.
[-max-safe-oper-temp <integer>] - Maximum Safe Operating Temperature in Degree Celsius
Displays information only about the storage bridges that have the temperature sensor with the maximum safe operating temperature you specify.

[-temp-reading <integer>] - Chassis Temperature Sensor Reading in Degree Celsius
Displays information only about the storage bridges that have the temperature sensors with the reading you specify.

[-temp-sensor-status {normal|warning|critical}] - Chassis Temperature Sensor Status
Displays information only about the storage bridges that have the temperature sensor with the status you specify.

[-temp-data-last-successful-refresh-timestamp {MM/DD/YYYY HH:MM:SS [(+|-)hh:mm]}] - Bridge Chassis Temperature Data Last Successful Refresh Timestamp
Displays information only about the storage bridges that match the temperature sensor data last successful refresh timestamp you specify.

[-fc-port-index-list <integer>, ...] - Bridge FC Port Index List
Displays information only about the storage bridges that have the ports with the indexes you specify.

[-fc-port-oper-state-list {unknown|online|offline}, ...] - Bridge FC Port Operational State List
Displays information only about the storage bridges that have the ports with the operational states you specify.

[-fc-port-admin-state-list {unknown|disabled|enabled}, ...] - Bridge FC Port Admin State List
Displays information only about the storage bridges that have the ports with the administrative states you specify.

[-fc-port-negotiated-data-rate-list {unknown|2|4|8|16}, ...] - Bridge FC Port Negotiated Data Rate List
Displays information only about the storage bridges that have the ports with the negotiated data rates you specify.

[-fc-port-negotiated-conn-mode-list {unknown|loop|n-port}, ...] - Bridge FC Port Negotiated Connection Mode List
Displays information only about the storage bridges that have the ports with the negotiated connection modes you specify.

[-fc-port-wwn-list <text>, ...] - Bridge FC Port WWN List
Displays information only about the storage bridges that have the ports with the world wide names you specify.

[-fc-port-data-last-successful-refresh-timestamp {MM/DD/YYYY HH:MM:SS [(+|-)hh:mm]}] - Bridge FC Port Data Last Successful Refresh Timestamp
Displays information only about the storage bridges that match the FC ports data last successful refresh timestamp you specify.

[-fc-port-stats-index-list <integer>, ...] - Bridge FC Port Index List
Displays information only about the storage bridges that have the ports with the indexes you specify.

[-fc-port-tx-words-list <integer>, ...] - Bridge FC Port Transmitted Word Count List
Displays information only about the storage bridges that have the ports with the number of transmitted words you specify.

[-fc-port-rx-words-list <integer>, ...] - Bridge FC Port Received Word Count List
Displays information only about the storage bridges that have the ports with the number of received words you specify.

[-fc-port-link-failures-list <integer>, ...] - Bridge FC Port Link Failure Count List
Displays information only about the storage bridges that have the ports with the number of link failures you specify.
[-fc-port-sync-losses-list <integer>, ...] - Bridge FC Port Sync Loss Count List
Displays information only about the storage bridges that have the ports with the number of synchronization losses you specify.

[-fc-port-invalid-crc-list <integer>, ...] - Bridge FC Port Invalid CRC Count List
Displays information only about the storage bridges that have the ports with the number of invalid CRCs you specify.

[-fc-port-stats-data-last-successful-refresh-timestamp {MM/DD/YYYY HH:MM:SS [(+|-)hh:mm]}] - Bridge FC Port Stats Last Successful Refresh Timestamp
Displays information only about the storage bridges that match the fc port stats data last successful refresh timestamp you specify.

[-sas-port-index-list <integer>, ...] - Bridge SAS Port Index List
Displays information only about the storage bridges that have the SAS ports with the indexes you specify.

[-sas-port-oper-state-list {unknown|online|offline|degraded}, ...] - Bridge SAS Port Operational State List
Displays information only about the storage bridges that have the SAS ports with the operational states you specify.

[-sas-port-phy1-oper-state-list {unknown|online|offline}, ...] - Bridge SAS Port PHY1 Operational State List
Displays information only about the storage bridges that have the SAS ports with the PHY1 operational states you specify.

[-sas-port-phy2-oper-state-list {unknown|online|offline}, ...] - Bridge SAS Port PHY2 Operational State List
Displays information only about the storage bridges that have the SAS ports with the PHY2 operational states you specify.

[-sas-port-phy3-oper-state-list {unknown|online|offline}, ...] - Bridge SAS Port PHY3 Operational State List
Displays information only about the storage bridges that have the SAS ports with the PHY3 operational states you specify.

[-sas-port-phy4-oper-state-list {unknown|online|offline}, ...] - Bridge SAS Port PHY4 Operational State List
Displays information only about the storage bridges that have the SAS ports with the PHY4 operational states you specify.

[-sas-port-admin-state-list {unknown|disabled|enabled}, ...] - Bridge SAS Port Administrative State List
Displays information only about the storage bridges that have the SAS ports with the administrative states you specify.

[-sas-port-data-rate-capability-list {unknown|1.5Gbps|3Gbps|6Gbps|12Gbps}, ...] - Bridge SAS Port Data Rate Capability List
Displays information only about the storage bridges that have the SAS ports with the data rate capabilities you specify.

[-sas-port-negotiated-data-rate-list {unknown|1.5Gbps|3Gbps|6Gbps|12Gbps}, ...] - Bridge SAS Port Negotiated Data Rate List
Displays information only about the storage bridges that have the SAS ports with the negotiated data rates you specify.

[-sas-port-wwn-list <text>, ...] - Bridge SAS Port WWN List
Displays information only about the storage bridges that have the SAS ports with the world wide names you specify.
[-sas-port-data-last-successful-refresh-timestamp \{MM/DD/YYYY HH:MM:SS \([+|-]hh:mm\)\}] - Bridge SAS Port DB Data Last Successful Refresh Timestamp
Displays information only about the storage bridges that match the SAS ports data last successful refresh
timestamp you specify.

[-sas-port-stats-phy-index-list <integer>, ...] - Bridge SAS Port PHY Index List
Displays information only about the storage bridges that have the SAS ports with the PHY indexes you
specify.

[-sas-port-link-changed-list <integer>, ...] - Bridge SAS Port Link Changed Count List
Displays information only about the storage bridges that have the SAS ports with the link changed count you
specify.

[-sas-port-invalid-crc-list <integer>, ...] - Bridge SAS Port Invalid CRC Count List
Displays information only about the storage bridges that have the SAS ports with the invalid CRCs you
specify.

[-sas-port-phy-reset-list <integer>, ...] - Bridge SAS Port PHY Reset Count List
Displays information only about the storage bridges that have the SAS ports with the PHY reset count you
specify.

[-sas-port-sync-losses-list <integer>, ...] - Bridge SAS Port Sync Loss Count List
Displays information only about the storage bridges that have the SAS ports with the synchronization losses
you specify.

[-sas-port-disparity-count-list <integer>, ...] - Bridge SAS Port Disparity Count List
Displays information only about the storage bridges that have the SAS ports with the disparity count you
specify.

[-sas-port-invalid-dword-list <integer>, ...] - Bridge SAS Port Invalid DWORD Count List
Displays information only about the storage bridges that have the SAS ports with the invalid DWORD count
you specify.

[-sas-port-stats-index-list <integer>, ...] - Bridge SAS Port Index List
Displays information only about the storage bridges that have the SAS ports with the indexes you specify.

[-sas-port-stats-data-rate-capability-list \{unknown|1.5Gbps|3Gbps|6Gbps|12Gbps\}, ...] - Bridge SAS Port Data Rate Capability List
Displays information only about the storage bridges that have the SAS ports with the data rate capabilities you
specify.

[-sas-port-stats-negotiated-data-rate-list \{unknown|1.5Gbps|3Gbps|6Gbps|12Gbps\}, ...] - Bridge SAS Port Negotiated Data Rate List
Displays information only about the storage bridges that have the SAS ports with the negotiated data rates you
specify.

[-sas-port-stats-last-successful-refresh-timestamp \{MM/DD/YYYY HH:MM:SS \([+|-]hh:mm\)\}] - Bridge SAS Port Statistics Data Last Successful Refresh Timestamp
Displays information only about the storage bridges that match the SAS port stats data last successful refresh
timestamp you specify.

[-fc-sfp-port-index-list <integer>, ...] - Bridge FC Port Index List
Displays information only about the storage bridges that have the FC ports with the indexes you specify.

[-fc-port-sfp-vendor-list \{text\}, ...] - Bridge FC Port SFP Vendor List
Displays information only about the storage bridges that have the FC ports with the SFP vendors you specify.
[-fc-port-sfp-serial-number-list <text>, ...] - Bridge FC Port SFP Serial Number List
Displays information only about the storage bridges that have the FC ports with the SFP serial numbers you specify.

[-fc-port-sfp-part-number-list <text>, ...] - Bridge FC Port SFP Part Number List
Displays information only about the storage bridges that have the FC ports with the SFP part numbers you specify.

[-fc-port-sfp-data-rate-capability-list (2Gb|4Gb|8Gb|16Gb), ...] - Bridge FC Port SFP Data Rate Capability List
Displays information only about the storage bridges that have the FC ports with the SFP data rate capabilities you specify.

[-fc-port-sfp-data-last-successful-refresh-timestamp {MM/DD/YYYY HH:MM:SS [+|-hh:mm]}, ...] - Bridge FC Port SFP Data Last Successful Refresh Timestamp
Displays information only about the storage bridges that match the FC ports SFP data last successful refresh timestamp you specify.

[-sas-qsfp-port-index-list <integer>, ...] - Bridge SAS Port Index List
Displays information only about the storage bridges that have the SAS ports with the indexes you specify.

[-sas-port-qsfp-vendor-list <text>, ...] - Bridge SAS Port QSFP Vendor List
Displays information only about the storage bridges that have the SAS ports with the QSFP vendors you specify.

[-sas-port-qsfp-serial-number-list <text>, ...] - Bridge SAS Port QSFP Serial Number List
Displays information only about the storage bridges that have the SAS ports with the QSFP serial numbers you specify.

[-sas-port-qsfp-type-list {unknown|optical|active-copper|passive-copper}, ...] - Bridge SAS Port QSFP Type List
Displays information only about the storage bridges that have the SAS ports with the QSFP types you specify.

[-sas-port-qsfp-part-number-list <text>, ...] - Bridge SAS Port QSFP Part Number List
Displays information only about the storage bridges that have the SAS ports with the QSFP part numbers you specify.

Displays information only about the storage bridges that match the SAS ports QSFP data last successful refresh timestamp you specify.

[-mini-sas-hd-index-list <integer>, ...] - Bridge Mini-SAS HD Index List
Displays information only about the storage bridges that have SAS ports with the Mini-SAS HD indexes that you specify.

[-mini-sas-hd-vendor-list <text>, ...] - Bridge Mini-SAS HD Vendor List
Displays information only about the storage bridges that have SAS ports with the Mini-SAS HD vendors that you specify.

[-mini-sas-hd-serial-number-list <text>, ...] - Bridge Mini-SAS HD Serial Number List
Displays information only about the storage bridges that have SAS ports with the Mini-SAS HD serial numbers that you specify.

[-mini-sas-hd-type-list <text>, ...] - Bridge Mini-SAS HD Type List
Displays information only about the storage bridges that have SAS ports with the Mini-SAS HD types that you specify.
[-mini-sas-hd-part-number-list <text>, ...] - Bridge Mini-SAS HD Part Number List
Displays information only about the storage bridges that have SAS ports with the Mini-SAS HD part numbers that you specify.

Displays information only about the storage bridges that match the SAS ports Mini-SAS HD data with the last successful refresh timestamp that you specify.

[-power-supply-index-list <integer>, ...] - Bridge Power Supply Index List
Displays information only about the storage bridges that have power supplies with the indexes that you specify.

[-power-supply-name-list <text>, ...] - Bridge Power Supply Name List
Displays information only about the storage bridges that have power supplies with the name that you specify.

[-power-supply-status-list {unknown|down|up}, ...] - Bridge Power Supply Status List
Displays information only about the storage bridges that have power supplies with the status that you specify.

[-power-supply-data-last-successful-refresh-timestamp {MM/DD/YYYY HH:MM:SS [{+|-}hh:mm]}] - Bridge Power Supply Data Last Successful Refresh Timestamp
Displays information only about the storage bridges that match the power supply last data with the last successful refresh timestamp that you specify.

[-node-list {<nodename>|local}, ...] - Node Name List
Displays information only about the storage bridges that are connected to the nodes you specify.

[-initiator-list <text>, ...] - Initiator List
Displays information only about the storage bridges that are connected to the nodes hosting the initiators you specify.

[-initiator-side-switch-port-name-list <text>, ...] - Initiator Side Switch Port Name List
Displays information only about the storage bridges that are connected to the initiator side switch ports you specify.

[-target-side-switch-port-name-list <text>, ...] - Target Side Switch Port Name List
Displays information only about the storage bridges that are connected to the target side switch ports you specify.

[-target-wwn-list <text>, ...] - Target Port WWN List
Displays information only about the storage bridges that match the target ports with world wide names you specify.

[-target-port-index-list <integer>, ...] - Target Port Index List
Displays information only about the storage bridges that match the target ports with indexes you specify.

**Examples**
The following example displays information about all storage bridges:

```
cluster1::> storage bridge show

storage disk commands

Manage physical disks

storage disk assign

Assign ownership of a disk to a system

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The `storage disk assign` command is used to assign ownership of an unowned disk or array LUN to a specific node. You can also use this command to change the ownership of a disk or an array LUN to another node. You can designate disk ownership by specifying disk names, array LUN names, wildcards, or all (for all disks or array LUNs visible to the node). For disks, you can also set up disk ownership autoassignment. You can also assign disks to a particular pool. You can also assign disks by copying ownership from another disk.

Parameters

`[-disk <disk path name>]` - Disk Path

This specifies the disk or array LUN that is to be assigned. Disk names take one of the following forms:

- Disks are named in the form `<stack-id>.<shelf>.<bay>`
- Disks on multi-disk carriers are named in the form `<stack-id>.<shelf>.<bay>.<lun>`
- Virtual disks are named in the form `<prefix>.<number>`, where prefix is the storage array's prefix and number is a unique ascending number.

Disk names take one of the following forms on clusters that are not yet fully upgraded to Data ONTAP 8.3:

- Disks that are not attached to a switch are named in the form `<node>:<host_adapter>:<loop_ID>`. For disks with a LUN, the form is `<node>:<host_adapter>:<loop_ID>L<LUN>`. For instance, disk number 16 on host adapter 1a on a node named node0a is named node0a:1a.16. The same disk on LUN lun0 is named node0a:1a.16L lun0.
- Disks that are attached to a switch are named in the form `<node>:<switch_name>:<switch_port>:<loop_ID>`. For disks with a LUN, the form is `<node>:<switch_name>:<switch_port>:<loop_ID>L<LUN>`. For instance, disk number 08 on port 11 of switch fc1 on a node named node0a is named node0a:fc1:11.08. The same disk on LUN lun1 is named node0a:fc1:11.08L lun1.

Before the cluster is upgraded to Data ONTAP 8.3, the same disk can have multiple disk names, depending on how the disk is connected. For example, a disk known to a node named alpha as alpha:1a.19 can be known to a node named beta as beta:0b.37. All names are listed in the output of queries and are equally valid. To determine a disk's unique identity, run a detailed query and look for the disk's universal unique identifier (UUID) or serial number.
A subset of disks or array LUNs can be assigned using the wildcard character (*) in the -disk parameter. Either the -owner, the -sysid, or the -copy-ownership-from parameter must be specified with the -disk parameter. Do not use the -node parameter with the -disk parameter.

|--all [true] - Assign All Disks

This optional parameter causes assignment of all visible unowned disks or array LUNs to the node specified in the -node parameter. The -node parameter must be specified with the -all parameter. When the -copy-ownership-from parameter is specified with the -node parameter, it assigns disk ownership based on the -copy-ownership-from parameter; otherwise it assigns ownership of the disks based on the -node parameter. Do not use the -owner or the -sysid parameter with the -all parameter.

|--type -T {ATA | BSAS | FCAL | FSAS | LUN | MSATA | SAS | SSD | VMDISK} - Storage Type

This optional parameter assigns ownership of a specific type of disk or array LUN (or a set of disks/array LUNs) to a node. The -count parameter must be specified with the -type parameter.

|--count -n <integer> - Disk Count

This optional parameter assigns ownership of a number of disks or array LUNs specified in the -count parameter, to a node.

|--auto [true] - Auto Assign

This optional parameter causes all visible disks eligible for autoassignment to be immediately assigned to the node specified in the -node parameter, regardless of the setting of the disk.auto_assign option. Only unowned disks on loops or stacks owned wholly by that system and which have the same pool information will be assigned. The -node parameter must be specified with the -auto parameter. Do not use the -owner, the -sysid, or the -copy-ownership-from parameter with the -auto parameter. When possible, use the -auto parameter rather than the -all parameter to conform to disk ownership best practices. The -auto parameter is ignored for array LUNs.

|--pool -p <integer> - Pool

This optional parameter specifies the pool to which a disk must be assigned. It can take values of Pool0 or Pool1.

{|--owner -o <nodename> - Owner Name

This optional parameter specifies the node to which the disk or array LUN has to be assigned.

|--sysid -s <nvramid> - New Owner ID

This optional parameter specifies the serial number (NVRAM ID) of the node to which the disk or array LUN has to be assigned.

|--copy-ownership-from <disk path name> - Disk Name to Copy Ownership

This optional parameter specifies the disk name from where the node needs to copy disk ownership information. You can use this parameter for disks to have the same ownership as the provided input disk.

|--checksum -c {block|zoned|advanced_zoned} - Checksum Compatibility

This optional parameter is used to set the checksum type for a disk or an array LUN. The possible values are block, zoned, and advanced_zoned. This operation will fail if the specified disk is incompatible with the specified checksum type. A newly created aggregate with zoned checksum array LUNs is assigned advanced zoned checksum (AZCS) checksum type. AZCS checksum type provides more functionality than the "version 1" zoned checksum type which has been supported in previous Data ONTAP releases. Zoned checksum spare array LUNs added to an existing zoned checksum aggregate continue to be zoned checksum. Zoned checksum spare array LUNs added to an AZCS checksum type aggregate use the AZCS checksum scheme for managing checksums. For some disks (e.g. FCAL, SSD, SAS disks), the checksum type cannot be modified. For more information on modifying the checksum type, refer to the "Physical Storage Management Guide".

|--force -f [true] - Force Flag

This optional parameter forces the assignment of ownership of an already owned disk to a node. This parameter could also be used to assign an array LUN with a redundancy error, for example, if the array LUN is...
available on only one path. For a disk which is part of a live aggregate, even specification of the \(-force\) parameter would not force the assignment, since it would be catastrophic.

\[-node | -N <nodename>\] - Node Name (For Auto Assign)

This optional parameter is used with either the \(-auto\) or the \(-all\) parameter. If used with the \(-auto\) parameter, all disks which are visible to the node specified in the \(-node\) parameter and which are eligible for auto assignment would be assigned to it. If used with the \(-all\) parameter, all unowned disks or array LUNs visible to the node would be assigned to it.

\{-root [true]\} - Root Partition of Root-Data or Root-Data1-Data2 Partitioned Disk (privilege: advanced)

This optional parameter assigns the root partition of a root-data/root-data1-data2 partitioned disk. You cannot use this parameter with disks that are part of a storage pool. The default value is \(false\).

\{-data [true]\} - Data Partition of Root-Data Partitioned Disk (privilege: advanced)

This optional parameter assigns the data partition of a root-data partitioned disk. You cannot use this parameter with disks that are part of a storage pool. The default value is \(false\).

\{-data1 [true]\} - Data1 Partition of Root-Data1-Data2 Partitioned Disk (privilege: advanced)

This optional parameter assigns the data1 partition of a root-data1-data2 partitioned disk. You cannot use this parameter with disks that are part of a storage pool. The default value is \(false\).

\{-data2 [true]\} - Data2 Partition of Root-Data1-Data2 Partitioned Disk (privilege: advanced)

This optional parameter assigns the data2 partition of a root-data1-data2 partitioned disk. You cannot use this parameter with disks that are part of a storage pool. The default value is \(false\).

### Examples

The following example assigns ownership of an unowned disk named 1.1.16 to a node named node1:

```bash
cluster1::> storage disk assign -disk 1.1.16 -owner node1
```

The following example assigns all unowned disks or array LUNs visible to a node named node1 to itself:

```bash
cluster1::> storage disk assign -all -node node1
```

The following example autoassigns all unowned disks (eligible for autoassignment) visible to a node named node1 to itself:

```bash
cluster1::> storage disk assign -auto -node node1
```

The following two examples show the working of the \(-force\) parameter with a spare disk that is already owned by another system:

```bash
cluster1::> storage disk assign -disk 1.1.16 -owner node1
Error: command failed: Failed to assign disks. Reason: Disk 1.1.16 is already owned.
```

```bash
cluster1::> storage disk assign -disk 1.1.16 -owner node1 -force
Success.
```

The following example assigns ownership of the set of unowned disks on <stack> 1, to a node named node1:
The following example assigns ownership of unowned disk 1.1.16 by copying ownership from disk 1.1.18:

```
cluster1::> storage disk assign -disk 1.1.16
   -copy-ownership-from 1.1.18
```

The following example assigns all unowned disks visible to a node named node1 by copying ownership from disk 1.1.18:

```
cluster1::> storage disk assign -all -node node1
   -copy-ownership-from 1.1.18
```

The following example assigns the root partition of disk 1.1.16 to node1.

```
cluster1::> storage disk assign -disk 1.1.16
   -owner node1
   -root true
```

The following example assigns the data partition of root-data partitioned disk 1.1.16 to node1.

```
cluster1::> storage disk assign -disk 1.1.16
   -owner node1
   -data true
```

The following example assigns the data1 partition of root-data1-data2 partitioned disk 1.1.24 to node1.

```
cluster1::> storage disk assign -disk 1.1.24
   -owner node1
   -data1 true
```

The following example assigns the data2 partition of root-data1-data2 partitioned disk 1.1.24 to node1.

```
cluster1::> storage disk assign -disk 1.1.24
   -owner node1
   -data2 true
```

### Storage Disk Fail

Fail the file system disk

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**
The `storage disk fail` command can be used to manually force a file system disk to fail. It is used to remove a file system disk that may be logging excessive errors and requires replacement. To unfail a disk, use the `storage disk unfail` command.

**Parameters**

- `disk <disk path name>` - Disk Name
  
  This parameter specifies the disk to be failed.

- `[-immediate | -i [true]]` - Fail immediately
  
  This parameter optionally specifies whether the disk is to be failed immediately. It is used to avoid Rapid RAID Recovery and remove the disk from the RAID configuration immediately. Note that when a file system disk has been removed in this manner, the RAID group to which the disk belongs enters degraded mode.
If a suitable spare disk is available, the contents of the disk being removed are reconstructed onto that spare disk.

### Examples

The following example fails a disk named 1.1.16 immediately:

```bash
cluster1::> storage disk fail -disk 1.1.16 -i true
WARNING: The system will not prefail the disk and its contents will not be copied to a replacement disk before being failed out. Do you want to fail out the disk immediately? [y|n]: y
```

### storage disk reassign

(DEPRECATED)-Change the default owner of all disks from one node to another

**Availability:** This command is available to cluster administrators at the advanced privilege level.

**Description**

The `storage disk reassign` is deprecated and may be removed in a future release of Data ONTAP. Disk reassignment is no longer required as part of a controller replacement procedure. For further information, see the latest controller or NVRAM FRU replacement flyer for your system. This command changes the ownership of all disks on a node to the ownership of another node. Use this command only when a node has a complete failure (for instance, a motherboard failure) and is replaced by another node. If the node's disks have already been taken over by its storage failover partner, use the `-force` parameter.

**Parameters**

- `--homeid <nvramid>` - Current Home ID
  This specifies the serial number of the failed node.

- `--newhomeid <nvramid>` - New Home ID
  This specifies the serial number of the node that is to take ownership of the failed node's disks.

- `--force [true]` - Force
  This optionally specifies whether to force the reassignment operation. The default setting is `false`.

### Examples

In the following example, a node named node0 and having serial number 12345678 has failed. Its disks have not been taken over by its storage failover partner. A replacement node with serial number 23456789 was installed and connected to node0's disk shelves. To assign node0's disks to the new node, start the new node and run the following command:

```bash
cluster::*> storage disk reassign --homeid 12345678 --newhomeid 23456789
node0's disks 1.1.11, 1.1.12, 1.1.13, 1.1.14, 1.1.15, 1.1.16, 1.1.23 and 1.1.24 were reassigned to new owner with serial number 23456789.
```

In the following example, a similar failure has occurred, except that node0's disks have been taken over by its storage failover partner, node1. A new node with serial number 23456789 has been installed and configured. To assign the disks that previously belonged to node0 to this new node, run the following command:

```bash
cluster::*> storage disk reassign --homeid 12345678 --newhomeid 23456789 --force true
node0's disks 1.1.11, 1.1.12, 1.1.13, 1.1.14, 1.1.15, 1.1.16, 1.1.23 and 1.1.24 were reassigned to new owner with serial number 23456789.
```
**storage disk refresh-ownership**

Refresh the disk ownership information on a node

**Availability:** This command is available to cluster administrators at the advanced privilege level.

**Description**

This command updates the disk ownership information for all the disks attached to a node to the latest view for all the nodes in the cluster. During normal operations, disk ownership is kept up to date automatically. In certain circumstances, however, disk ownership must be updated manually. If this is required, EMS messages will indicate that this command should be run. If the -node parameter is provided, the disk ownership information is updated only on the node specified.

**Parameters**

[-node \(<nodename>|local\)] - Node

If this parameter is provided, the disk ownership information is updated only on the node specified.

**Examples**

The following example refreshes the disk ownership information for all the nodes in the cluster:

```
cluster1::> storage disk refresh-ownership
```

**storage disk remove**

Remove a spare disk

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**

The `storage disk remove` command removes the specified spare disk from the RAID configuration, spinning the disk down when removal is complete.

This command does not remove disk ownership information from the disk. Therefore, if you plan to reuse the disk in a different storage system, you should use the `storage disk removeowner` command instead. See the "Physical Storage Management Guide" for the complete procedure.

**NOTE:** For systems with multi-disk carriers, it is important to ensure that none of the disks in the carrier are filesystem disks before attempting removal. To convert a filesystem disk to a spare disk, see `storage disk replace`.

**Parameters**

-\(\text{-disk }<\text{disk path name}>\) - Disk Name

This parameter specifies the disk to be removed.

**Examples**

The following example removes a spare disk named 1.1.16:

```
cluster1::> storage disk remove -disk 1.1.16
```

**Related references**

- `storage disk removeowner` on page 757
- `storage disk replace` on page 758
storage disk remove-reservation

Removes reservation from an array LUN marked as foreign.

**Availability:** This command is available to `cluster` administrators at the `advanced` privilege level.

**Description**
The `storage disk remove-reservation` command removes persistent reservation from a specified foreign array LUN.

**Parameters**

- `-disk <disk path name>` - Disk Name
  This specifies the disk from which persistent reservation is to be removed.

**Examples**
The following example removes the persistent reservation from a disk named node1:switch01:port.126L1.

```
cluster1::> storage disk remove-reservation -disk node1:switch01:port.126L1
```

storage disk removeowner

Remove disk ownership

**Availability:** This command is available to `cluster` administrators at the `admin` privilege level.

**Description**
The `storage disk removeowner` command removes ownership from a specified disk. Then disk can then be reassigned to a new owner.

**Parameters**

- `-disk <disk path name>` - Disk Name
  This specifies the disk whose ownership is to be removed.

  | `[-root [true]]` - Root Partition of Root-Data/Root-Data1-Data2 Partitioned Disk (privilege: advanced) |
  | This optional parameter removes ownership of the root partition of a root-data/root-data1-data2 partitioned disk. You cannot use this parameter with disks that are part of a storage pool. The default value is `false`. |

  | `[-data [true]]` - Data Partition of Root-Data Partitioned Disk (privilege: advanced) |
  | This optional parameter removes ownership of the data partition of a root-data partitioned disk. You cannot use this parameter with a root-data1-data2 partitioned disk or disks that are part of a storage pool. The default value is `false`. |

  | `[-data1 [true]]` - Data1 Partition of a Root-Data1-Data2 Partitioned Disk (privilege: advanced) |
  | This optional parameter removes ownership of the data1 partition of a root-data1-data2 partitioned disk. You cannot use this parameter with a root-data partitioned disk or disks that are part of a storage pool. The default value is `false`. |

  | `[-data2 [true]]` - Data2 Partition of a Root-Data1-Data2 Partitioned Disk (privilege: advanced) |
  | This optional parameter removes ownership of the data2 partition of a root-data1-data2 partitioned disk. You cannot use this parameter with a root-data partitioned disk or disks that are part of a storage pool. The default value is `false`. |

**Examples**
The following example removes the ownership from a disk named 1.1.27.
cluster1::> storage disk removeowner -disk 1.1.27

The following example removes ownership of the root partition on disk 1.1.16.

cluster1::> storage disk removeowner -disk 1.1.16 -root true

The following example removes ownership of the data partition on disk 1.1.16.

cluster1::> storage disk removeowner -disk 1.1.16 -data true

The following example removes ownership of the data1 partition on disk 1.1.23.

cluster1::> storage disk removeowner -disk 1.1.23 -data1 true

The following example removes ownership of the data2 partition on disk 1.1.23.

cluster1::> storage disk removeowner -disk 1.1.23 -data2 true

---

**storage disk replace**

Initiate or stop replacing a file-system disk

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**

The *storage disk replace* command starts or stops the replacement of a file system disk with spare disk. When you start a replacement, Rapid RAID Recovery begins copying data from the specified file system disk to a spare disk. When the process is complete, the spare disk becomes the active file system disk and the file system disk becomes a spare disk. If you stop a replacement, the data copy is halted, and the file system disk and spare disk retain their initial roles.

**Parameters**

- `-disk <disk path name>` - Disk Name

  This specifies the file system disk that is to be replaced. Disk names take one of the following forms:

  - Disks are named in the form `<stack-id>.<shelf>.<bay>`
  - Disks on multi-disk carriers are named in the form `<stack-id>.<shelf>.<bay>.<lun>`
  - Virtual disks are named in the form `<prefix>.<number>`, where prefix is the storage array’s prefix and number is a unique ascending number.

  Disk names take one of the following forms on clusters that are not yet fully upgraded to Data ONTAP 8.3:

  - Disks that are not attached to a switch are named in the form `<node>:<host_adapter>:<loop_ID>`. For disks with a LUN, the form is `<node>:<host_adapter>:<loop_ID>L<LUN>`. For instance, disk number 16 on host adapter 1a on a node named node0a is named node0a:1a.16. The same disk on LUN lun0 is named node0a:1a.16Llun0.
  - Disks that are attached to a switch are named in the form `<node>:<switch_name>:<switch_port>:<loop_ID>`. For disks with a LUN, the form is `<node>:<switch_name>:<switch_port>:<loop_ID>L<LUN>`. For instance, disk number 08 on port 11 of switch fc1 on a node named node0a is named node0a:fc1:11.08. The same disk on LUN lun1 is named node0a:fc1:11.08Llun1.

  Before the cluster is upgraded to Data ONTAP 8.3, the same disk can have multiple disk names, depending on how the disk is connected. For example, a disk known to a node named alpha as alpha:1a.19 can be known to a

---

758 Commands: Manual Page Reference
node named beta as beta:0b.37. All names are listed in the output of queries and are equally valid. To determine a disk's unique identity, run a detailed query and look for the disk's universal unique identifier (UUID) or serial number.

```
-action {start | stop} - Action
```

This specifies whether to start or stop the replacement process.

```
-replacement <disk path name> - Replacement
```

This specifies the spare disk that is to replace the file system disk.

```
-allow-same-carrier [true] - Allow Same RAID Group Within Carrier
```

This parameter can be used to allow two disks housed in the same carrier to be in the same RAID group when you replace a disk in an aggregate.

Having disks in the same carrier in the same RAID group is not desirable because a carrier failure can cause a simultaneous outage for two disks in the same RAID group. You can replace a disk in an aggregate with a disk that causes this situation, but when an alternate disk becomes available, Data ONTAP automatically initiates a series of disk copy operations to put the disks into different RAID groups. For this reason, you should use this parameter only when necessary. When possible, ensure that disks housed in the same carrier are in different RAID groups.

This parameter affects only the disk replace operation. It is not a persistent attribute of the aggregate.

```
-allow-mixing | -m [true] - Allow Mixing of Disks of Different RPM or Pool
```

This optional parameter specifies whether the disk can be replaced with another disk of different RPM or from different Pool. This parameter affects only the current disk replacement operation.

**Examples**

The following example begins replacing a file system disk named 1.0.16 with a spare disk named 1.1.14.

```
cluster1::> storage disk replace -disk 1.0.16 -replacement 1.1.14 -action start
```

---

### storage disk set-foreign-lun

Sets or Unsets an array LUN as foreign

**Availability:** This command is available to `cluster` administrators at the `admin` privilege level.

**Description**

The `storage disk set-foreign-lun` command sets or unsets a specified array LUN as foreign. This command will enable/disable the feature of importing the data from foreign LUN.

**Parameters**

```
-disk <disk path name> - Disk Name
```

This parameter specifies the array LUN which is to be set or unset as foreign.

```
-is-foreign-lun [true] - Is Foreign LUN
```

If the parameter value specified is `true` then array LUN is set as foreign. If the parameter value specified is `false` then array LUN foreignness is cleared.

**Examples**

The following example shows how to set an array LUN as foreign:

```
cluster1::> storage disk set-foreign-lun -disk EMC-1.1 -is-foreign-lun true
```
The following example shows how to mark an array LUN as not foreign:

```
cluster1::> storage disk set-foreign-lun -disk EMC-1.1 -is-foreign-lun false
```

**storage disk set-led**

Identify disks by turning on their LEDs

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**

The `storage disk set-led` command controls the LED of a specified disk.

You can turn an LED on or off, cause it to blink or stop blinking, or test it.

This command is useful for locating a disk in its shelf.

**Parameters**

```
-action <on|off|blink|blinkoff|testall|resetall> - Action
```

This parameter specifies the state to which the LED is to be set. Possible values include the following:

- **on** - The LED is lit steadily
- **off** - The LED is not lit
- **blink** - The LED blinks
- **blinkoff** - The LED stops blinking and is not lit
- **testall** - This tests the operation of every disk enclosure's hardware and drivers per node. Do not use this value in normal operation.
- **resetall** - This resets the LED of every disk on the node and lights up the LED of disks with faults.

```
-disk <disk path name> - Disk Name
```

This specifies the disk whose LED is to be set. Disk names take one of the following forms:

- Disks are named in the form `<stack-id>.<shelf>.<bay>`
- Disks on multi-disk carriers are named in the form `<stack-id>.<shelf>.<bay>.<lun>`
- Virtual disks are named in the form `<prefix>.<number>`, where prefix is the storage array's prefix and number is a unique ascending number.

Disk names take one of the following forms on clusters that are not yet fully upgraded to Data ONTAP 8.3:

- Disks that are not attached to a switch are named in the form `<node>:<host_adapter>:<loop_ID>`. For disks with a LUN, the form is `<node>:<host_adapter>:<loop_ID>L<LUN>`. For instance, disk number 16 on host adapter 1a on a node named node0a is named node0a:1a.16. The same disk on LUN lun0 is named node0a:1a.16Llun0.
- Disks that are attached to a switch are named in the form `<node>:<switch_name>:<switch_port>:<loop_ID>`. For disks with a LUN, the form is `<node>:<switch_name>:<switch_port>:<loop_ID>L<LUN>`. For instance, disk number 08 on port 11 of switch fc1 on a node named node0a is named node0a:fc1:11.08. The same disk on LUN lun1 is named node0a:fc1:11.08Llun1.

Before the cluster is upgraded to Data ONTAP 8.3, the same disk can have multiple disk names, depending on how the disk is connected. For example, a disk known to a node named alpha as alpha:1a.19 can be known to a
node named beta as beta:0b.37. All names are listed in the output of queries and are equally valid. To
determine a disk's unique identity, run a detailed query and look for the disk's universal unique identifier
(UUID) or serial number.

| [-adapter <text>] - Adapter Name
| The name of the adapter to which the shelves of disks of interest are attached to.
| [-node {<nodename>|local}] - Node Name
| The node for which action is to be taken.
| [-duration <integer>] - Duration (minutes)
| This specifies the duration, in minutes, that the LED is to remain in the specified state. Only actions "on" and
| "blink" are supported.
| [-iteration <integer>] - Test iterations
| This specifies the number of iterations to run the action for. Only action "test-all" is supported.

**Examples**

The following example causes the LEDs on all disks whose names match the pattern Cluster1* to turn on for 5 minutes:

```
Cluster1::> storage disk set-led -disk Cluster1* -action on -duration 5
```

The following example causes the LEDs on all disks attached to adapter 0b on Node2 to turn on for 1 minute:

```
Cluster1::> storage disk set-led -node Node2 -adapter 0b -action on -duration 1
```

The following example resets the LEDs on all disks on the local node and causes the LEDs of disks with faults to turn on:

```
Cluster1::> storage disk set-led -action resetall
```

The following example causes the LEDs on all disks whose names match the pattern Cluster1* to turn on for 2 minutes:

```
Cluster1::> storage disk set-led -disk Cluster1* -action on -duration 2
```

The following example tests the LEDs on all disks owned by the local node for 3 iterations:

```
Cluster1::> storage disk set-led -action testall -iteration 3
```

**storage disk show**

Display a list of disk drives and array LUNs

**Availability:** This command is available to `cluster` administrators at the `admin` privilege level.

**Description**

The `storage disk show` command displays information about disks and array LUNs. Where it appears in the remainder of
this document "disk" may refer to either a disk or an array LUN. By default, the command displays the following information
about all disks in column style output:

- Disk name
- Usable space on the disk, in human readable units
- Shelf number
- Bay number
- Container type (aggregate, broken, foreign, labelmaint, maintenance, mediator, remote, shared, spare, unassigned, unknown, volume, or unsupported)
- Position (copy, data, dparity, orphan, parity, pending, present, shared or tparity)
- Container name
- Owning node name

To display detailed information about a single disk, use the `-disk` parameter.

**Parameters**

```
[-fields <fieldname>, ...]
```

Displays the specified fields for all disks, in column style output.

```
[-broken]
```

Displays the following RAID-related information about broken disks:

- Original owning node name
- Checksum compatibility
- Disk name
- Outage reason
- Host bus adapter
- Shelf number
- Bay number
- Primary port / Channel
- Pool
- Disk type
- RPM (Revolutions per minute)
- Usable size in human readable units
- Physical size in human readable units
- Current owner node

```
[-errors]
```

Displays the following disk information about the disks which have errors.

- Disk Name
- Error Type
- Error Description and corresponding corrective action

```
[-longop]
```

Displays the following information about long-running disk operations, in column style output:

- Disk name
- Whether the disk is marked as prefailed
- Whether the disk is being replaced
• Whether the disk is zeroed
• Copy destination
• Percentage of copy complete
• Percentage of zeroing complete
• Percentage of reconstruction complete

| [-maintenance ] |
Displays the following RAID-related information about disks in the maintenance center:
• Original owning node name
• Checksum compatibility
• Disk name
• Outage Reason
• Host bus adapter
• Shelf number
• Bay number
• Primary port / Channel
• Pool
• Disk type
• RPM (Revolutions per minute)
• Usable size in human readable units
• Physical size in human readable units
• Current owner node

| [-ownership ] |
Displays the following ownership-related information:
• Disk name
• Aggregate name
• Home node name
• Owning node name
• Disaster recovery home node name
• Home node system id
• Owning node system id
• Disaster recovery home node system id
• Reservation node system id
• SyncMirror pool
[-partition-ownership]
Displays the following ownership-related information for partitioned disks:

- Disk name
- Aggregate name
- Owner of root partition on a partitioned disk
- Owner system id of root partition on a partitioned disk
- Owner of data or data1 partition on a root-data or a root-data1-data2 partitioned disk respectively
- Owner system id of data or data1 partition on a root-data or a root-data1-data2 partitioned disk respectively
- Owner of data2 partition on a root-data1-data2 partitioned disk
- Owner system id of data2 partition on a root-data1-data2 partitioned disk
- Owner of the disk which is partitioned
- Owner system id of the disk which is partitioned

[-physical]
Displays the following information about the disk's physical attributes, in column style output:

- Disk name
- Disk type
- Disk vendor
- Disk model
- Firmware revision level
- RPM (Revolutions per minute)
- BPS (Bytes per sector)

[-port]
Displays the following path-related information:

- Disk name and disk port associated with disk primary path
- Disk name and disk port associated with the disk secondary path, for a multipath configuration
- Type, shelf, and bay information for the disks

[-raid]
Displays the following RAID-related information:

- Disk name
- Container type (aggregate, broken, labelmaint, maintenance, mediator, remote, shared, spare, unassigned, unknown, or volume)
- Outage reason
- Position (copy, data, dparity, orphan, parity, pending, present, shared or tparity)
- RAID group name
- Aggregate name
[-raid-info-for-aggregate]
Displays the following RAID-related information about the disks used in an aggregate:

- Owning node name
- Aggregate name
- Plex name
- RAID group name
- Position (copy, data, dparity, orphan, parity, pending, present, shared or tparity)
- Disk name
- Host bus adapter
- Shelf number
- Bay number
- Primary port / Channel
- Pool
- Disk type
- RPM (Revolutions per minute)
- Usable size in human readable units
- Physical size in human readable units

When this parameter is specified, RAID groups that use shared disks are not included. Use storage aggregate show-status to show information for all RAID groups and aggregates.

[-spare]
Displays the following RAID-related information about available spare disks:

- Original owning node name
- Checksum compatibility
- Disk name
- Host bus adapter
- Shelf number
- Bay number
- Primary port / Channel
- Pool
- Disk type
- Disk class
- RPM (Revolutions per minute)
- Usable size in human readable units
- Physical size in human readable units
- Current owner node
[-ssd-wear]
Displays the following wear life related information about solid state disks:

- Rated Life Used: An estimate of the percentage of device life that has been used, based on the actual device usage and the manufacturer's prediction of device life. A value greater than 99 indicates that the estimated endurance has been used, but this does not necessarily indicate a device failure. Omitted if value is unknown.

- Spare Blocks Consumed Limit: Spare blocks consumed percentage limit reported by the device. When the Spare Blocks Consumed percentage for the device reaches this read-only value, Data ONTAP initiates a disk copy operation to prepare to remove the device from service. Omitted if value is unknown.

- Spare Blocks Consumed: Percentage of device spare blocks that have been used. Each device has a number of spare blocks that will be used when a data block can no longer be used to store data. This value reports what percentage of the spares have already been consumed. Omitted if value is unknown.

[-virtual-machine-disk-info]
Displays information about Data ONTAP virtual disks, their mapped datastores and their specific backing device attributes, such as: disk or LUN, adapter and initiator details (if applicable).

- Disk name.
- Name of the node.
- Data ONTAP-supplied serial number of the system disk.
- Size of the system disk.
- Name of the disk backing store. A backing store represents a storage location for virtual machine files. It can be a VMFS volume, a directory on network-attached storage, or a local file system path.
- File name of the virtual disk used by the hypervisor. Each Data ONTAP disk is mapped to a unique VM disk file.
- Type of the disk backing store. It can be a VMFS volume, a directory on network-attached storage, or a local file system path.
- Size of the disk backing store.
- Full path to the backing store for network-attached storage. This field is valid only for NAS connections.
- Backing adapter PCI device ID for the virtual disk, for example "50:00.0".
- Backing adapter device name, for example "vmhba32".
- Backing adapter model type, for example "LSI1064E".
- Backing adapter driver name of the initiator.
- The iSCSI name of the disk backing target. This field is valid only for iSCSI connections.
- The iSCSI IP address of the disk backing target. This field is valid only for iSCSI connections.
- SCSI device name for the backing disk. It takes the form target-id:lun-id, for example "2:1".
- Hypervisor-assigned unique ID of the backing device (disk or LUN).
- Backing disk partition number where the corresponding VM disk file resides.
- Size of the backing device (disk or LUN).
- Backing device manufacturer, for example "FUJITSU" or "IBM".

766  Commands: Manual Page Reference
• Backing device model, for example "MBE2073RC" or "LUN".
• Error (if any) while retrieving virtual disk details.

```
[vmdisk-backing-info]
Displays information about the backing disks on certain Data ONTAP-v models:
  • Disk name
  • Backing disk vendor
  • Backing disk model
  • Backing disk serial number
  • Backing disk device id
```

```
[foreign] (privilege: advanced)
Displays the following foreign LUN import related information about foreign disks:
  • Disk name
  • Array name
  • Capacity in sectors
  • Capacity in mb
  • Serial Number
```

```
[physical-location] (privilege: advanced)
Displays the following information about disks:
  • Disk name
  • Container type
  • Primary path
  • Location
  • Home node name
  • Physical size in human readable units
```

```
[primary-paths] (privilege: advanced)
Displays the following information about disks:
  • Disk Name
  • Shelf
  • Bay
  • Container Type
  • Primary Path
```

```
[instance]
Displays detailed disk information. If no disk path name is specified, this parameter displays the same detailed information for all disks as does the -disk parameter. If a disk path name is specified, then this parameter displays the same detailed information for the specified disks as does the -disk parameter.
```
[-disk <disk path name>] - Disk Name
Displays detailed information about the specified disks. Disk names take one of the following forms:

- Disks are named in the form <stack-id>.<shelf>.<bay>
- Disks on multi-disk carriers are named in the form <stack-id>.<shelf>.<bay>.<lun>
- Virtual disks are named in the form <prefix>.<number>, where prefix is the storage array's prefix and number is a unique ascending number.

Disk names take one of the following forms on clusters that are not yet fully upgraded to Data ONTAP 8.3:

- Disks that are not attached to a switch are named in the form <node>:<host_adapter>:<loop_ID>. For disks with a LUN, the form is <node>:<host_adapter>:<loop_ID>L<LUN>. For instance, disk number 16 on host adapter 1a on a node named node0a is named node0a:1a.16. The same disk on LUN lun0 is named node0a:1a.16Llun0.
- Disks that are attached to a switch are named in the form <node>:<switch_name>:<switch_port>:<loop_ID>. For disks with a LUN, the form is <node>:<switch_name>:<switch_port>:<loop_ID>L<LUN>. For instance, disk number 08 on port 11 of switch fc1 on a node named node0a is named node0a:fc1:11.08. The same disk on LUN lun1 is named node0a:fc1:11.08Llun1.

Before the cluster is upgraded to Data ONTAP 8.3, the same disk can have multiple disk names, depending on how the disk is connected. For example, a disk known to a node named alpha as alpha:1a.19 can be known to a node named beta as beta:0b.37. All names are listed in the output of queries and are equally valid. To determine a disk's unique identity, run a detailed query and look for the disk's universal unique identifier (UUID) or serial number.

[-owner {<nodename>|local}] - Owner
Selects information about disks that are owned by the specified node.

[-owner-id <nvramid>] - Owner System ID
Selects the disks that are owned by the node with the specified system ID.

[-is-foreign {true|false}] - Foreign LUN (privilege: advanced)
Selects information about array LUNs that have been declared to be foreign LUNs.

[-uid <text>] - Disk Unique ID
Selects the disks whose unique id matches this parameter value. A disk unique identifier has the form:

[-aggregate <aggregate name>] - Aggregate
Selects information about disks that belong to the specified aggregate.

[-array-name <array name>] - Array Name
Selects information about the LUNs presented by the specified storage array.

[-average-latency <integer>] - Average I/O Latency Across All Active Paths
Selects information about disks that have the specified average latency.

[-bay <integer>] - Bay
Selects information about disks that are located in the carrier within the specified shelf bay.

[-bps <integer>] - Bytes Per Sector
Selects information about disks that have the specified number of bytes per sector. Possible settings are 512, 520, 4096, and 4160.
[-carrier-id <text>] - Carrier ID
Selects information about disks that are located within the specified multi-disk carrier.

[-checksum-compatibility {advanced_zoned | block | none}] - Checksum Compatibility
Selects information about disks that have the specified checksum compatibility.

[-class {capacity | performance | archive | solid-state | array | virtual}] - Disk Class
Selects information about disks that have the specified disk class.
• capacity = Capacity-oriented, near-line disk types. Includes disk types FSAS, BSAS and ATA.
• performance = Performance-oriented, enterprise class disk types. Includes disk types FCAL and SAS.
• archive = Archive class SATA disks in multi-disk carrier storage shelves. Includes disk type MSATA.
• solid-state = Solid-state drives. Includes disk type SSD.
• array = Logical storage devices backed by storage arrays and used by Data ONTAP as disks. Includes disk type LUN.
• virtual = Virtual disks that are formatted and managed by VMware ESX. Includes disk type VMDISK.

[-container-type {aggregate | broken | foreign | labelmaint | maintenance | mediator | remote | shared | spare | unassigned | unknown | unsupported}] - Container Type
Selects information about disks that have the specified container type.
• Aggregate = Disk is used as a physical disk in an aggregate.
• Broken = Disk is in broken pool.
• Foreign = Array LUN has been marked foreign.
• Labelmaint = Disk is in online label maintenance list.
• Maintenance = Disk is in maintenance center.
• Mediator = A mediator disk is a disk used on non-shared HA systems hosted by an external node which is used to communicate the viability of the storage failover between non-shared HA nodes.
• Remote = Disk belongs to the remote cluster.
• Shared = Disk is partitioned or in a storage pool.
• Spare = Disk is a spare disk.
• Unassigned = Disk ownership has not been assigned.
• Unknown = Container is currently unknown. This is the default setting.
• Unsupported = Disk is not supported.

[-container-name <text>] - Container Name
Selects information about disks that have the specified container name.
If a disk is in an aggregate or storage pool, the container name is the name of the aggregate or storage pool.
Spare disks show the SyncMirror Pool to which they belong.
Partitioned disks could return multiple aggregate names.

[-copy-destination <disk path name>] - Copy Destination Name
Selects information about disks whose contents are being copied (due to either Rapid RAID Recovery or disk replacement) to the specified spare disk.
[~-copy-percent <integer>] - Percentage of Copy Complete
Selects information about disks that are involved as either a source or destination of a copy operation, (due to either disk replacement or Rapid RAID Recovery) and that have the specified percentage of the copy operation completed.

[~-data-owner {<nodename>|local}] - Owner of Data Partition of Root-Data Partitioned Disk
Selects information about disks that have the specified data partition owner name. Used with root-data partitioned disks.

[~-data1-owner {<nodename>|local}] - Owner of Data1 Partition of Root-Data1-Data2 Partitioned Disk
Selects information about disks that have the specified data1 partition owner name. Used with root-data1-data2 partitioned disks.

[~-data2-owner {<nodename>|local}] - Owner of Data2 Partition of Root-Data1-Data2 Partitioned Disk
Selects information about disks that have the specified data2 partition owner name. Used with root-data1-data2 partitioned disks.

[~-data-home {<nodename>|local}] - Home Owner of Data Partition of Root-Data Partitioned Disk
Selects information about disks that have the specified data partition home owner name. Used with root-data partitioned disks.

[~-data1-home {<nodename>|local}] - Home Owner of Data1 Partition of Root-Data1-Data2 Partitioned Disk
Selects information about disks that have the specified data1 partition home owner name. Used with root-data1-data2 partitioned disks.

[~-data2-home {<nodename>|local}] - Home Owner of Data2 Partition of Root-Data1-Data2 Partitioned Disk
Selects information about disks that have the specified data2 partition home owner name. Used with root-data1-data2 partitioned disks.

[~-data-owner-id <nvramid>] - Owner System ID of Data Partition of Root-Data Partitioned Disk
Selects information about disks that have the specified data partition owner system ID. Used with root-data partitioned disks.

[~-data1-owner-id <nvramid>] - Owner System ID of Data1 Partition of Root-Data1-Data2 Partitioned Disk
Selects information about disks that have the specified data1 partition owner system ID. Used with root-data1-data2 partitioned disks.

[~-data2-owner-id <nvramid>] - Owner System ID of Data2 Partition of Root-Data1-Data2 Partitioned Disk
Selects information about disks that have the specified data2 partition owner system ID. Used with root-data1-data2 partitioned disks.

Selects information about disks that have the specified data partition home owner system ID. Used with root-data partitioned disks.

[~-data1-home-id <nvramid>] - Home Owner System ID of Data1 Partition of Root-Data1-Data2 Partitioned Disk
Selects information about disks that have the specified data1 partition home owner system ID. Used with root-data1-data2 partitioned disks.

[~-data2-home-id <nvramid>] - Home Owner System ID of Data2 Partition of Root-Data1-Data2 Partitioned Disk
Selects information about disks that have the specified data2 partition home owner system ID. Used with root-data1-data2 partitioned disks.

[~-disk-io-kbps-total <integer>] - Total Disk Throughput in KBPS Across All Active Paths
Selects information about disks that have attained the specified I/O throughput on all connected paths.

[~-disk-iops-total <integer>] - Total Disk IOPs Across All Active Paths
Selects information about disks that have achieved the specified number of IOPs per second on all connected paths.
[-diskpathnames <disk path name>, ...] - list of path based disk names
   Selects information about disks that have all of the specified path names.

[-effective-rpm <integer>] - Effective RPM
   Selects information about disks with the specified effective rotational speed.

[-dr-home {<nodename>|local}] - Disaster Recovery Home
   Selects information about disks that have the specified Disaster home node.

[-dr-home-id <nvramid>] - Disaster Recovery Home System ID
   Selects information about disks whose Disaster home node has the specified system id.

[-error-type {onepath|onedomain|control|foreign|toobig|toosmall|invalidblocksize|
targetsymmap|deviceassymmap|failovermisconfig|unknown|netapp|fwdownrev|qualfail|diskfail|
notallflashdisk}, ...] - Error Type
   Selects information about disks that have the specified error types.
   • onepath = The array LUN is accessible only via a single path.
   • onedomain = The array LUN is accessible only via a single fault domain.
   • control = The array LUN cannot be used because it is a control device.
   • foreign = The array LUN is marked as foreign and has some external SCSI reservations other than those
     from Data ONTAP.
   • toobig = The array LUN exceeds the maximum array LUN size that Data ONTAP supports.
   • toosmall = The array LUN is less than the minimum array LUN size that Data ONTAP supports.
   • invalidblocksize = The array LUN is not a valid block size.
   • targetsymmap = The array LUN is presented more than once on a single target port.
   • deviceassymmap = The array LUN is presented with multiple IDs.
   • failovermisconfig = The array LUN is configured with inconsistent failover methods.
   • unknown = The array LUN from a storage array that is not supported by this version of Data ONTAP.
   • netapp = A SAN front-end LUN from one Data ONTAP system that is presented as external storage to
     another Data ONTAP system.
   • fwdownrev = The disk firmware is a down version.
   • qualfail = The disk is not supported.
   • diskfail = The disk is in a failed state.
   • notallflashdisk = The disk does not match the All-Flash Optimized personality of the system.

[-firmware-revision <text>] - Firmware Revision
   Selects information about disks that have the specified firmware revision level.

[-home {<nodename>|local}] - Home
   Selects information about disks that have the specified home node.

[-home-id <nvramid>] - Home System ID
   Selects information about disks whose home node has the specified system ID.

[-host-adapter <text>] - Primary Path Host Adapter
   Selects information about disks that are currently using the specified Host Bus Adapter.
[-hw-minimum-os <text>] - Hardware Minimum Supported Data ONTAP Version
Selects information about disks that have the specified hardware minimum supported Data ONTAP version.

[-import-in-progress {true|false}] - Foreign LUN import in progress
Selects information about the array LUNs that are currently being imported. If this parameter is specified, the command displays information only about the disk or disks that are currently being used for importing data.

[-initiator <text>,...]] - Initiator Port
Selects information about disks that are visible to the initiator specified. Disks that are not currently in use by that initiator are included.

[-initiator-iops <integer>,...]] - Number of IOPS on Initiator (Rolling Average)
Selects information about disks that are visible to an initiator that has executed the specified number of IOPs.

[-initiator-io-kbps <integer>,...]] - Kbytes of I/O per second on Initiator (Rolling Average)
Selects information about disks visible to an initiator that has executed I/O at the specified throughput.

[-initiator-lun-in-use-count <integer>,...]] - Number of LUNs in the in-use state on this initiator
Selects information about disks with a path through an initiator that has the specified in-use-count.

[-initiator-side-switch-port <text>,...]] - Initiator Side Switch Port
Selects information about disks visible to an initiator connected to the specified switch port.

[-is-multidisk-carrier {true|false}] - Multi Disk Carrier?
Selects information about disks that are located within a multi-disk carrier.

[-is-local-attach {true|false}] - Indicates If the Disk Is Local to This Cluster
Selects information about disks attached to the local(true) or remote(false) MetroCluster site.

[-location <nodename>|local]] - Physical Location
Selects information about disks attached to the specified node.

[-location-id <nvramid>] - The system ID of the node where the disk is attached
Selects information about disks attached to the node with the specified system ID.

[-lun <integer>,...]] - LUN ID
Selects information about the specified LUNs.

[-lun-iops <integer>,...]] - Number IOPS per second on disk (Rolling Average)
Selects information about the LUNs that have reached the specified number of IOPs.

[-lun-io-kbps <integer>,...]] - Kbytes/sec on Disk (Rolling Average)
Selects information about the LUNs that have reached the specified I/O throughput.

[-lun-path-use-state <text>,...]] - The Use State of the LUN on this path
Selects information about LUNs reporting the specified in-use state.

[-model <text>] - Model
Selects information about disks of the specified model.

[-nodelist <nodename>|local>,...]] - Controller name
Selects information about disks that are visible to all of the specified nodes.

[-outage-reason <text>] - Outage Reason
Selects information about disks that are not in service for the specified reason. Possible values are: admin failed, admin removed, admin testing, evacuated, bad label, bypassed, failed, init failed, label version, labeled broken, labelmaint, LUN resized, missing, not responding, predict failure, rawsize shrank, recovering, sanitizing, sanitized, SnapLock Disk, testing, unassigned, unknown.

[-path-error-count <integer>] - Path Error Count
Selects information about disks that are visible on a path that has incurred the specified number of errors.
[-path-iops <integer>, ...] - Number of IOPS on Path (Rolling Average)
    Selects information about disks on those paths that have reached the specified number of IOPs.

[-path-io-kbps <integer>, ...] - Kbytes of I/O per second on Path (Rolling Average)
    Selects information about disk with paths that have reached the specified I/O throughput

[-path-link-errors <integer>, ...] - Link Error count on path
    Selects information about disks with paths that have incurred the specified number of FC link errors.

[-path-lun-in-use-count <integer>, ...] - Number of LUNs in the in-use state on this path
    Selects information about disks with paths that have the specified in-use-count.

[-path-quality <integer>, ...] - Percentage of weighted error threshold
    Selects information about disks on paths that have incurred the specified number of errors. The value
    displayed is a measure of the health of a path expressed as a percentage of an error threshold. Once a path has
    reached or surpassed the error threshold, another path will be selected for I/O transfer, if there is one available.

[-physical-size-mb <integer>] - Physical Size (MB)
    Selects information about disks that have the specified physical capacity, in megabytes.

[-physical-size [<integer> {KB|MB|GB|TB|PB}]] - Physical Size
    Selects information about disks that have the specified physical capacity, in human readable units.

[-physical-size-512b <integer>] - Physical Size in Units of 512 Bytes
    Selects information about disks that have the specified physical capacity, in 512-byte chunks. This parameter
    is present only for backwards compatibility with Data ONTAP 8.0.

[-plex <text>] - Plex Name
    Selects information about disks that belong to the specified RAID plex.

[-pool <text>] - Assigned Pool
    Selects information about disks that belong to the specified SyncMirror pool (pool0 or pool1).

[-port-speed <text>, ...] - Port Speed
    Selects information about disks that are served by a Host Bus Adapter that is running at the specified port
    speed.

[-position <diskPositionType>] - Disk Position
    Selects information about disks that have the specified position within their disk container.

[-prefailed {true|false}] - Marked for Rapid RAID Recovery?
    Selects information about disks that match the specified parameter value indicating whether the disk is either
    awaiting or is in process of Rapid RAID Recovery.

[-preferred-target-port {true|false}, ...] - Whether or not target port group is preferred (privilege: advanced)
    Selects information about disks that match the specified parameter value indicating whether the backing
    storage is ALUA (Asymmetric Logical Unit Access) capable and has specified the array target port on this
    path to be a preferred target port for I/O.

[-primary-port <text>] - Primary Path Disk Port
    Selects information about disks that use the specified primary port.

[-raid-group <text>] - Raid Group Name
    Selects information about disks that belong to the specified RAID group.

[-reconstruction-percent <integer>] - Percentage of Reconstruction Complete
    Selects information about disks that are being reconstructed and that have the specified percentage of the
    reconstruction operation completed.
[-replacing {true|false}] - Being Replaced?
Selects information about disks that match the specified boolean value indicating whether the disk is either awaiting or in process of disk replacement.

[-reservation-key <text>] - Reservation Key
If this parameter is specified, the command displays information only about the disk or disks that have the specified persistent reservation key.

[-reservation-type {rs|we|re|ea|sa|wero|earo|wear|eaar|none}] - Reservation Type
If this parameter is specified, the command displays information only about the disk or disks that have the specified persistent reservation type. Possible values are: rs, we, re, ea, sa, wero, earo, wear, eaar, or none.

[-reserver-id <integer>] - Reservation System ID
Selects information about disks that are reserved by the node with the specified system ID.

[-root-owner {<nodename>|local}] - Owner of Root Partition of Root-Data/Root-Data1-Data2 Partitioned Disk
Selects information about disks that have the specified root partition owner name. Used with root-data/root-data1-data2 partitioned disks.

[-root-owner-id <nvramid>] - Owner System ID of Root Partition of Root-Data/Root-Data1-Data2 Partitioned Disk
Selects information about disks that have the specified root partition owner system ID. Used with root-data/root-data1-data2 partitioned disks.

[-root-home {<nodename>|local}] - Home Owner of Root Partition of Root-Data/Root-Data1-Data2 Partitioned Disk
Selects information about disks that have the specified root partition home owner name. Used with root-data/root-data1-data2 partitioned disks.

[-root-home-id <nvramid>] - Home Owner System ID of Root Partition of Root-Data/Root-Data1-Data2 Partitioned Disk
Selects information about disks that have the specified root partition home owner system ID. Used with root-data/root-data1-data2 partitioned disks.

[-rpm <integer>] - Revolutions Per Minute
Selects information about disks that have the specified rotational speed.

[-secondary-name <disk path name>] - Secondary Path Name
Selects information about disks that use the specified secondary path name, for multipath configuration.

[-secondary-port <text>] - Secondary Path Disk Port
Selects information about disks that use the specified secondary port.

[-serial-number <text>] - Serial Number
Selects information about the disk that has the specified serial number.

[-storage-pool <text>] - Storage Pool Name
Selects information about disks that belong to the specified SSD storage pool.

[-shelf <integer>] - Shelf
Selects information about disks that are located within the specified shelf.

[-shelf-uid <text>] - Shelf UID
Selects information about disks that are located within a shelf with the specified Shelf UID.

[-stack-id <integer>] - Stack ID
A cluster unique id for a collection of one or more interconnected shelves.
[-target-iops <integer>, ...] - Number of IOPS to Target (Rolling Average)
Selects information about disks that are visible on target ports that have performed the specified number of IOPs.

[-target-io-kbps <integer>, ...] - Kbytes of I/O per second to Target (Rolling Average)
Selects information about disks that are visible on target ports that have reached the specified I/O throughput.

[-target-lun-in-use-count <integer>, ...] - Number of LUNs in the in-use state on this target
Selects information about disks with a path through a target port that has the specified in-use-count.

[-target-port-access-state <text>, ...] - Failover optimization type
Selects information about disks that are visible on target ports that have the specified access state.

[-target-side-switch-port <text>, ...] - Target Side Switch Port
Selects information about disks that are visible on target ports identified by the switch port to which they are connected.

[-target-wwpn <text>, ...] - Target Port
Selects information about disks that are visible on target ports identified by their World Wide Port Name.

[-tpgn <integer>, ...] - Target Port Group Number
Selects information about disks that belong to the specified Target Port Group Number.

[-type {ATA | BSAS | FCAL | FSAS | LUN | MSATA | SAS | SSD | VMDISK}] - Disk Type
Selects information about disks that have the specified disk type.

[-usable-size-mb <integer>] - Usable Size (MB)
Selects information about disks that have the specified usable space, in megabytes.

[-usable-size <integer> {<integer> [KB|MB|GB|TB|PB]}] - Usable Size
Selects information about disks that have the specified usable space, in human readable units.

[-vendor <text>] - Vendor Name
Selects information about disks that have the specified vendor.

[-vmdisk-device-id <integer>, ...] - Virtual Disk Device ID
Selects information about disks that have the specified virtual disk device ID.

[-zeroed {true|false}] - Zeroed?
Selects information about disks that have (true) or have not (false) been fully pre-zeroed.

[-zeroing-percent <integer>] - Percentage of Zeroing Complete
Selects information about disks that are zeroing and have the specified percentage complete.

[-carrier-serialno <text>] - Carrier Serial Number
Selects information about disks that are located within the multi-disk carrier specified by the serial number.

Examples
The following example displays information about all disks:

```
cluster1::> storage disk show

**storage disk unfail**

Unfail a broken disk

**Availability:** This command is available to cluster administrators at the **advanced** privilege level.

**Description**

The `storage disk unfail` command can be used to unfail a broken disk.

If the attempt to unfail the disk is unsuccessful, the disk remains in the broken state.

The disk unfail command prompts for confirmation unless you specify the `-quiet` parameter.

**Parameters**

- `-disk <disk path name>` - **Disk Name**
  
  This parameter specifies the disk to be unfailed.

- `[-spare] | -s [true]` - **Make the Disk Spare**
  
  This parameter specifies whether the unfailed disk will be made a spare disk. The disk is forced to become a spare disk if this parameter is specified.

  If this parameter is not specified, the disk is brought back into its parent aggregate. Setting this parameter might result in the aggregate coming back online if it is not complete or online. The default value is false.

- `[-quiet] | -q [true]` - **Confirmations off**
  
  You can set this parameter to true to suppress the confirmation messages. However, before proceeding with the command, you should be aware that the confirmation message contains important information about the effect of unfailing a disk. This command cannot be reversed once it is invoked. The default value is false.
storage disk updatefirmware

(DEPRECATED) - Update disk firmware

Availability: This command is available to cluster administrators at the admin privilege level.

Description

Note: This command is deprecated and may be removed in a future release of Data ONTAP. Use the "storage disk firmware update" command.

The storage disk updatefirmware command updates the firmware on one or more disks. You can download the latest firmware by using the storage firmware download command. You can specify a list of one or more disks whose firmware is to be updated by using the -disk parameter, or you can update the firmware on all local disks by omitting the -disk parameter.

Parameters

[-disk <disk path name>,...] - Disk

This specifies the disk or disks whose firmware is to be updated.

If you do not specify this option, all local disks' firmware is updated.

Examples

The following example updates the firmware on all disks:

cluster1::> storage disk updatefirmware

Related references

storage disk firmware update on page 784
storage firmware download on page 840

storage disk zerospares

Zero non-zeroed spare disks

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The storage disk zerospares command zeroes all non-zeroed spare disks in all nodes or a specified node in the cluster. A node must be online to zero disks. Zeroing a disk writes zeros to the entire disk and must be done before a disk can be reused in another aggregate.

Parameters

[-owner (<nodename>|local)] - Owner

If this parameter is specified, only non-zeroed spares assigned to the specified node will be zeroed. Otherwise, all non-zeroed spares in the cluster will be zeroed.
Examples
The following example zeroes all non-zeroed spares owned by a node named node4:

```
cluster1:/> storage disk zerospares -owner node4
```

### storage disk error commands

The error directory

### storage disk error show

Display disk component and array LUN configuration errors.

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**
The `storage disk error show` command displays disk component and array LUN configuration errors.

**Parameters**

```plaintext
{[-fields <fieldname>, ...]
  If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

[-instance]
  If you specify the `-instance` parameter, the command displays detailed information about all fields.

[-uid <text>] - UID
  Displays the error information of the disk whose unique ID matches the value you specify. A disk unique identifier has the form:

[-array-name <array name>] - Array Name
  Displays the errors of the storage array whose name you specified.

[-node {<nodename>|local}] - Controller Name
  Displays the error information for the disks on the clustered node whose name you specified.

[-disk <disk path name>] - Disk
  Displays detailed error information about the disk you specified.

[-serial-number <text>] - Serial Number
  Displays the error information for the disk whose serial number you specified.

[-error-id <integer>, ...] - Error ID
  Displays the error information for the disks whose Error IDs match IDs you specified.

[-error-type {onepath|onedomain|control|foreign|toobig| toosmall|invalidblocksize| targetasymmap|deviceasymmap|failovermisconfig|unknown|netapp|fwdownrev|qualfail|diskfail|notallflasdisk}, ...] - Error Type
  Displays all disk errors of the error types you specified, grouped by type.
  - onepath = The array LUN is accessible only via a single path.
  - onedomain = The array LUN is accessible only via a single fault domain.
• control = The array LUN cannot be used because it is a control device.
• foreign = The array LUN is marked as foreign and has some external SCSI reservations other than those from Data ONTAP.
• toobig = The array LUN exceeds the maximum array LUN size that Data ONTAP supports.
• toosmall = The array LUN is less than the minimum array LUN size that Data ONTAP supports.
• invalidblocksize = The array LUN is not a valid block size.
• targetasymmap = The array LUN is presented more than once on a single target port.
• deviceasymmap = The array LUN is presented with multiple IDs.
• failovermisconfig = The array LUN is configured with inconsistent failover methods.
• unknown = The array LUN from a storage array that is not supported by this version of Data ONTAP.
• netapp = A SAN front-end LUN from one Data ONTAP system that is presented as external storage to another Data ONTAP system.
• fwdownrev = The disk firmware is a down version.
• qualfail = The disk is not supported.
• diskfail = The disk is in a failed state.
• notallflashdisk = The disk does not match the All-Flash Optimized personality of the system.

Examples
The following example displays configuration errors seen in the system:

```
cluster1:/> storage disk error show
Disk             Error Type        Error Text
---------------- ----------------- --------------------------------------------
1.02.0           qualfail          This disk failed dynamic disk qualification. Update the Disk Qualification Package.
```

storage disk firmware commands

The firmware directory

storage disk firmware revert

Revert disk firmware

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
The `storage disk firmware revert` command reverts firmware on all disks or a specified list of disks on a node.

You can specify a list of one or more disks whose firmware is to be reverted by using the `-disk` parameter.

You can revert the firmware on all the disks owned by a node by using the `-node` parameter.

This command can make the disks inaccessible for up to five minutes after the start of its execution. Therefore, the network sessions that use the concerned node must be terminated before running the `storage disk firmware revert` command. This is particularly true for CIFS sessions that might be terminated when this command is executed.
If you need to view the current firmware versions, use the `storage disk show -fields firmware-revision` command. The following example displays partial output from the `storage disk show -fields firmware-revision` command, where the firmware version for the disks is NA02:

```
cluster1::> storage disk show -fields firmware-revision
  disk  firmware-revision
  -------- -----------------
  1.0.0    NA02
  1.0.1    NA02
  1.0.2    NA02
  1.0.3    NA02
  1.0.4    NA02
  1.0.5    NA02
```

The firmware files are stored in the `/mroot/etc/disk_fw` directory on the node. The firmware file name is in the form of "product-ID.revision.LOD". For example, if the firmware file is for Seagate disks with product ID X225_ST336704FC and the firmware version is NA01, the file name is X225_ST336704FC.NA01.LOD. If the node in this example contains disks with firmware version NA02, the `/mroot/etc/disk_fw/X225_ST336704FC.NA01.LOD` file is downloaded to every disk when you execute this command.

**How to Revert the Firmware for an HA Pair in a Cluster**

Use the following procedure to perform a revert on the disks in an HA environment:

- Make sure that the nodes are not in takeover or giveback mode.
- Download the latest firmware on both nodes by using the `storage firmware download` command.
- Revert the disk firmware on Node A's disks by entering the `storage disk firmware revert -node node-A` command.
- Wait until the `storage disk firmware revert` command completes on Node A, and then revert the firmware on Node B's disks by entering the `storage disk firmware revert -node node-B` command.

**Parameters**

```
{ -disk <disk path name>, ... - Disk Name
  Specifies the disk or disks whose firmware is to be reverted.
| -node {<nodename>|local} - Node Name
  Specifies the node name. The disk firmware will be reverted on all the disks owned by the node specified by this parameter.
```

**Examples**

If you need to view the current firmware versions, use the `storage disk show -fields firmware-revision` command. The following example displays partial output from the `storage disk show -fields firmware-revision` command, where the firmware version for the disks is NA02:

```
cluster1::> storage disk show -fields firmware-revision
  disk  firmware-revision
  -------- -----------------
  1.0.0    NA02
  1.0.1    NA02
  1.0.2    NA02
  1.0.3    NA02
  1.0.4    NA02
  1.0.5    NA02
```

The following example reverts the firmware on all disks owned by `cluster-node-01`:
Related references

*storage disk show* on page 761

*storage firmware download* on page 840

**storage disk firmware show-update-status**

Display disk firmware update status.

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

**Description**

The *storage disk firmware show-update-status* command displays the state of the background disk firmware update process.

**Parameters**

*[-fields <fieldname>, ...]*

If you specify the *-fields <fieldname>, ...* parameter, the command output also includes the specified field or fields. You can use *-fields ?* to display the fields to specify.

*[-instance]*

If you specify the *-instance* parameter, the command displays detailed information about all fields.

*[-node <nodename>] - Node*

Selects the node that matches this parameter value.

*[-num-waiting-download <integer>] - The Number of Disks Waiting to Download*

Selects the nodes whose number of disks waiting to download by the BDFU process matches this parameter value.
[-total-completion-estimate <integer>] - Estimated Duration to Completion (mins)

Selects the nodes whose Background Disk Firmware Update (BDFU) completion time estimate matches this parameter value. This indicates the amount of estimated time required for BDFU to complete the firmware update cycle.

[-average-duration-per-disk <integer>] - Average Firmware Update Duration per Disk (secs)

Selects the nodes whose BDFU reports the average time required to update a single disk matches this parameter value. This indicates the average amount of time required by each disk drive.

[-unable-to-update <disk path name>, ...] - List of Disks with a Failed Update

Selects the nodes whose unable to update disk list matches this parameter value. This is a list of disks that failed to update the firmware.

[-update-status {off|running|idle}] - Background Disk Firmware Update Status

Selects the nodes whose BDFU process status matches this parameter value. Possible values are:

- off - The BDFU process is off.
- running - The BDFU process is on and currently running.
- idle - The BDFU process is on and is currently idle.

<td>120</td>
<td>0 -</td>
</tr>
<tr>
<td>node3</td>
<td>off</td>
<td>0</td>
<td>120</td>
<td>0 -</td>
</tr>
</tbody>
</table>
```

### storage disk firmware update

Update disk firmware

**Availability:** This command is available to cluster administrators at the advanced privilege level.

**Description**

Use the `storage disk firmware update` command to manually update firmware on all disks or a specified list of disks on a node. However, the recommended way to update disk firmware in a cluster is to enable automatic background firmware update by enabling the `-bkg-firmware-update` parameter for all of the nodes in the cluster. You can do this by entering the `storage disk option modify -node * -bkg-firmware-update` command.

You can download the latest firmware on the node by using the `storage firmware download` command.

You can specify a list of one or more disks whose firmware is to be updated by using the `-disk` parameter.

You can update the firmware on all the disks owned by a node by using the `-node` parameter.

This command can make the disks inaccessible for up to five minutes after the start of its execution. Therefore, the network sessions that use the concerned node must be terminated before running the `storage disk firmware update` command. This is particularly true for CIFS sessions that might be terminated when this command is executed.

The firmware is automatically downloaded to disks, which report previous versions of the firmware. For information on automatic firmware update downloads, see "Automatic versus Manual Firmware Download".
If you need to view the current firmware versions, use the `storage disk show -fields firmware-revision` command. The following example displays partial output from the `storage disk show -fields firmware-revision` command, where the firmware version for the disks is NA01:

```
cluster1::> storage disk show -fields firmware-revision
          disk     firmware-revision
            -------- -----------------
            1.0.0    NA01
            1.0.1    NA01
            1.0.2    NA01
            1.0.3    NA01
            1.0.4    NA01
            1.0.5    NA01
```

The firmware files are stored in the `/mroot/etc/disk_fw` directory on the node. The firmware file name is in the form of "product-ID.revision.LOD". For example, if the firmware file is for Seagate disks with product ID X225_ST336704FC and the firmware version is NA02, the filename is X225_ST336704FC.NA02.LOD. The revision part of the file name is the number against which the node compares each disk's current firmware version. If the node in this example contains disks with firmware version NA01, the `/mroot/etc/disk_fw/X225_ST336704FC.NA02.LOD` file is used to update every eligible disk when you execute this command.

Automatic versus Manual Firmware Download

The firmware is automatically downloaded to those disks that report previous versions of firmware following a system boot or disk insertion. Note that:

- A manual download is a disruptive operation that makes disks inaccessible for up to five minutes after the download is started. Network sessions that use the node must be terminated before running the `storage disk firmware update` command.
- The firmware is not automatically downloaded to the node's partner node in an HA pair.
- The firmware is not automatically downloaded to unowned disks on nodes configured to use software-based disk ownership.
- The `bkg-firmware-update` parameter controls how the automatic firmware download feature works:
  - If the `bkg-firmware-update` parameter is set to off, then the `storage disk firmware update` will update the firmware on the drives in parallel.
  - If the `bkg-firmware-update` parameter is set to on, then the `storage disk firmware update` will only automatically update filesystem disks contained in RAID4 volumes. Firmware updates for spares and filesystem disks contained within RAID-DP, mirrored RAID-DP and mirrored RAID4 volumes will be done in a nondisruptive manner in the background after boot. Firmware downloads for these disks will be done sequentially by temporarily taking them offline one at a time for the duration of the download. After the firmware is updated, the disk will be brought back online and restored to its normal operation.

During an automatic download to an HA environment, the firmware is not downloaded to the disks owned by the HA partner. When you use the `storage disk firmware update` command, the firmware is:

- Updated on every disk regardless of whether it is on the A-loop, the B-loop, or in an HA environment.
- If the node is configured in a software-based disk ownership system, only disks owned by this node are updated.

Follow the instructions in "How to Update the Firmware for an HA Pair in a Cluster" to ensure that the updating process is successful. Data ONTAP supports redundant path configurations for disks in a non-HA configuration. The firmware is automatically downloaded to disks on the A-loop or B-loop of redundant configurations that are not configured in an HA pair and are not configured to use software-based disk ownership.

Automatic Background Firmware Update
The firmware can be updated in the background so that the firmware update process does not impact the clients. This functionality is controlled with the bkg-firmware-update parameter. You can modify the parameter by using the CLI storage disk option modify 

   -node node_name -bkg-firmware-update on|off

command. The default value for this parameter is "on".

When disabled or set to "off", storage disk firmware update will update the firmware in automated mode. This means that all disks which had older firmware revision will be updated regardless of whether they are spare or filesystem disks.

When enabled or set to "on", the background storage disk firmware update will update firmware in automated mode only on disks that can be successfully taken offline from active filesystem RAID groups and from the spare pool. For filesystem disks, this capability currently exists within RAID-DP, mirrored RAID-DP, and mirrored RAID4 volume types. To ensure a faster boot process, no firmware is downloaded to spares and filesystem disks contained in the previous volume types. However, firmware updates for disks within RAID4 volumes are done at boot. RAID4 volumes can be temporarily (or permanently) upgraded to RAID-DP to automatically enable background firmware update capability.

This provides the highest degree of safety available, without the cost of copying data from each disk in the system twice. Disks are taken offline one at a time and then the firmware is updated on them. The disk is brought online after the firmware update and a mini/optimized reconstruct happens for any writes, which occurred while the disk was offline. Background disk firmware update will not occur for a disk if its containing RAID group or the volume is not in a normal state (for example, if the volume/plex is offline or the RAID group is degraded). However, due to the continuous polling nature of background disk firmware update, firmware updates will resume after the RAID group/plex/volume is restored to a normal mode. Similarly, background disk firmware updates are suspended for the duration of any reconstruction within the system.

How to Update the Firmware for an HA Pair in a Cluster

The best way to update the firmware in a cluster with HA pairs is to use automatic background firmware update by enabling the option bkg-firmware-update parameter for each node. Enable the -bkg-firmware-update parameter on all the nodes by entering the storage disk option modify 

   -node node_name -bkg-firmware-update on

command. Alternatively, use the following procedure to successfully perform a manual update on the disks in an HA environment:

• Make sure that the nodes are not in takeover or giveback mode.
• Download the latest firmware on both the nodes by using the storage firmware download command.
• Install the new disk firmware on Node A’s disks by entering the storage disk firmware update -node node-A command.
• Wait until the storage disk firmware update command completes on Node A, and then install the new disk firmware on Node B’s disks by entering the storage disk firmware update -node node-B command.

Parameters

   { -disk <disk path name>, ... - Disk

   Specifies the disk or disks whose firmware is to be updated.

   | -node {<nodename>|local}) - node

   Specifies the node name. The disk firmware will be updated on all the disks owned by the node specified by this parameter.

Examples

If you need to view the current firmware versions, use the storage disk show -fields firmware-revision command. The following example displays partial output from the storage disk show -fields firmware-revision command, where the firmware version for the disks is NA01:

```
cluster1::> storage disk show -fields firmware-revision

<table>
<thead>
<tr>
<th>disk</th>
<th>firmware-revision</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.0.0</td>
<td>NA01</td>
</tr>
<tr>
<td>1.0.1</td>
<td>NA01</td>
</tr>
<tr>
<td>1.0.2</td>
<td>NA01</td>
</tr>
</tbody>
</table>
```
The following example updates the firmware on all disks owned by cluster-node-01:

```
cluster1::*> storage disk firmware update -node cluster-node-01
Warning: Disk firmware updates can be disruptive to the system. Updates involve power cycling all of the affected disks, as well as suspending disk I/O to the disks being updated. This delay can cause client disruption. Takeover/giveback operations on a high-availability (HA) group will be delayed until the firmware update process is complete. Disk firmware updates should only be done one node at a time. Disk firmware updates can only be performed when the HA group is healthy; they cannot be performed if the group is in takeover mode.
Do you want to continue with disk firmware updates? {y|n}: y
Info: Updating disk firmware for disks on cluster-node-01.
```

The following example updates the firmware on disk 1.5.0 which is owned by node cluster-node-04:

```
cluster1::*> storage disk firmware update -disk 1.5.0
Warning: Disk firmware updates can be disruptive to the system. Updates involve power cycling all of the affected disks, as well as suspending disk I/O to the disks being updated. This delay can cause client disruption. Takeover/giveback operations on a high-availability (HA) group will be delayed until the firmware update process is complete. Disk firmware updates should only be done one node at a time. Disk firmware updates can only be performed when the HA group is healthy; they cannot be performed if the group is in takeover mode.
Do you want to continue with disk firmware updates? {y|n}: y
Info: Updating disk firmware for disks on cluster-node-04.

**Storage disk option Command**

Manage disk options

The `storage disk option modify` command displays or modifies the settings of disk options.

**storage disk option modify**

Modify disk options

**Availability:** This command is available to `cluster` administrators at the `admin` privilege level.

**Description**

The `storage disk option modify` command modifies the background firmware update setting, automatic copy setting, controls automatic disk assignment of all disks assigned to a specified node, or modifies the policy of automatic disk assignment of unowned disks.
Parameters

- **node {<nodename>|local} - Node**
  
  This parameter specifies the node that owns the disks whose options are to be modified.

- **-bkg-firmware-update {on|off} - Background Firmware Update**
  
  This parameter specifies whether firmware updates run as a background process. The default setting is on, which specifies that firmware updates to spare disks and file system disks is performed nondisruptively via a background process. If the option is turned off, automatic firmware updates occur at system startup or during disk insertion.

- **-autocopy {on|off} - Auto Copy**
  
  This parameter specifies whether data is to be automatically copied from a failing disk to a spare disk in the event of a predictive failure. The default setting is on. It is sometimes possible to predict a disk failure based on a pattern of recovered errors that have occurred. In such cases, the disk reports a predictive failure. If this option is set to on, the system initiates Rapid RAID Recovery to copy data from the failing disk to an available spare disk. When data is copied, the disk is marked as failed and placed in the pool of broken disks. If a spare is not available, the node continues to use the disk until it fails. If the option is set to off, the disk is immediately marked as failed and placed in the pool of broken disks. A spare is selected and data from the missing disk is reconstructed from other disks in the RAID group. The disk does not fail if the RAID group is already degraded or is being reconstructed. This ensures that a disk failure does not lead to the failure of the entire RAID group.

- **-autoassign {on|off} - Auto Assign**
  
  This parameter specifies whether automatic assignment of unowned disks is enabled or disabled. The default setting is on. This parameter is used to set both a node-specific and a cluster-wide disk option.

- **-autoassign-policy {default|bay|shelf|stack} - Auto Assignment Policy**
  
  This parameter defines the granularity at which auto assign should work. This option is ignored if the -autoassign option is off. Auto assignment can be done at the stack/loop, shelf, or bay level. The possible values for the option are default, stack, shelf, and bay. The default value is platform dependent. It is stack for all non-entry platforms and single-node systems, whereas it is bay for entry-level platforms.

Examples

The following example sets the background firmware update setting to on for all disks belonging to a node named node0:

```
cluster1::> storage disk option modify -node node0 -bkg-firmware-update on
```

The following example shows how to enable auto assignment for the disks on node1:

```
cluster1::> storage disk option modify -node node1 -autoassign on
cluster1::> storage disk option show

<table>
<thead>
<tr>
<th>Node</th>
<th>Bkg. FW. Upd.</th>
<th>Auto Copy</th>
<th>Auto Assign</th>
<th>Auto Assign Policy</th>
</tr>
</thead>
<tbody>
<tr>
<td>node1</td>
<td>on</td>
<td>on</td>
<td>on</td>
<td>default</td>
</tr>
<tr>
<td>node2</td>
<td>on</td>
<td>off</td>
<td></td>
<td>default</td>
</tr>
</tbody>
</table>

2 entries were displayed.
```

The following example shows how to modify the auto assignment policy on node1:

```
cluster1::> storage disk option modify -node node1 -autoassign-policy bay
cluster1::> storage disk option show

<table>
<thead>
<tr>
<th>Node</th>
<th>Bkg. FW. Upd.</th>
<th>Auto Copy</th>
<th>Auto Assign</th>
<th>Auto Assign Policy</th>
</tr>
</thead>
<tbody>
<tr>
<td>node1</td>
<td>on</td>
<td>on</td>
<td>on</td>
<td>bay</td>
</tr>
<tr>
<td>node2</td>
<td>on</td>
<td>off</td>
<td></td>
<td>default</td>
</tr>
</tbody>
</table>

2 entries were displayed.
```
**storage disk option show**

Display a list of disk options

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**
The `storage disk option show` command displays the settings of the following disk options:

- Background firmware update
- Automatic copying of data to a spare disk in the event of a predictive failure
- Automatic assignment of disks
- Policy that governs automatic assignment of unowned disks

**Parameters**

```
[-fields <fieldname>, ...]
```
If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

```
[-instance]
```
If you specify the `-instance` parameter, the command displays detailed information about all fields.

```
[-node <nodename>|local] - Node
```
Selects the node that owns the disks. If this parameter is not specified, the command displays information about the disk options on all the nodes.

```
[-bkg-firmware-update {on|off}] - Background Firmware Update
```
Selects the disks that match this parameter value.

```
[-autocopy {on|off}] - Auto Copy
```
Selects the disks that match this parameter value.

```
[-autoassign {on|off}] - Auto Assign
```
Displays the auto assignment status of unowned disks. The default value is *on*.

```
[-autoassign-policy {default|bay|shelf|stack}] - Auto Assignment Policy
```
Selects the disks that match the automatic assignment policy value:

- Default
- Stack/loop
- Shelf
- Bay

**Examples**
The following example displays disk-option settings for disks owned by all nodes in the cluster:

```
cluster1::> storage disk option show
Node           BKg. FW. Upd.  Auto Copy     Auto Assign     Auto Assign Policy
-------------  -------------  ------------  -------------    ------------------
node0          on             on            on            default
```

**storage disk commands**
storage encryption commands

The encryption directory

storage encryption disk commands

Manage encryption objects for self-encrypting disks

storage encryption disk destroy

Cryptographically destroy a self-encrypting disk

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The storage encryption disk destroy command cryptographically destroys a self-encrypting disk (SED), making it incapable of performing I/O operations. This command performs the following operations:

• Employs the inherent erase capability of SEDs to cryptographically sanitize the disk
• Permanently locks the disk to prevent further data access
• Changes the data and FIPS authentication keys to random values that are not recorded except within the SED.

Use this command with extreme care. The only mechanism to restore the disk to usability (albeit without the data) is the storage encryption disk revert-to-original-state operation that is available only on disks that have the physical secure ID (PSID) printed on the disk label.

The destroy command requires you to enter a confirmation phrase before proceeding with the operation.

The command releases the cluster shell after launching the operation. Monitor the output of the storage encryption disk show-status command for command completion.

Upon command completion, remove the destroyed SED from the system.

Parameters
-disk <disk path name> - Disk Name
This parameter specifies the name of the disk you want to cryptographically destroy. See the man page for the storage disk modify command for information about disk-naming conventions.

Examples
The following command cryptographically destroys the disk 1.10.20:

```
cluster1:/> storage encryption disk destroy 1.10.20
Warning: This operation will cryptographically destroy 1 spare or broken self-encrypting disks on 1 node.
You cannot reuse destroyed disks unless you revert them to their original state using the PSID value.
To continue, enter destroy disk :destroy disk
Info: Starting destroy on 1 disk.
```
View the status of the operation by using the "storage encryption disk show-status" command.

cluster1::>

If you do not enter the correct confirmation phrase, the operation is aborted:

cluster1::> storage encryption disk destroy 1.10.2*

Warning: This operation will cryptographically destroy 5 spare or broken self-encrypting disks on 1 node.

You cannot reuse destroyed disks unless you revert them to their original state using the PSID value.

To continue, enter destroy disk :yes

No disks destroyed.

cluster1::>

storage encryption disk show-status on page 797

storage encryption disk modify

Modify self-encrypting disk parameters

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The storage encryption disk modify command changes the data and FIPS-compliance protection parameters of self-encrypting disks (SEDs). The current data AK and FIPS AK of the SED are required to effect changes to the respective AKs and FIPS compliance, and must also be available from the key servers.

The command releases the cluster shell after launching the operation. Monitor the output of the storage encryption disk show-status command for command completion.

Note: To properly protect data at rest on a SED and place it into compliance with its FIPS certification requirements, set both the Data and FIPS-compliance AKs to a value other than the default manufacture secure ID (MSID), indicated by a key ID with the special value 0x0. Verify the key IDs by using the storage encryption disk show and storage encryption disk show-fips commands.

Parameters

-disk <disk path name> - Disk Name

This parameter specifies the name of the SED that you want to modify.

[ -data-key-id <text>] - Key ID of the New Data Authentication Key

This parameter specifies the key ID associated with the data AK that you want the SED to use for future authentications. When the provided key ID is the MSID, data at rest on the SED is not protected from unauthorized access. Setting this parameter to a non-MSID value automatically engages the power-on-lock protections of the device, so that when the device is power-cycled, the system must authenticate with the device using the AK to reenable I/O operations.

[ -fips-key-id <text>] - Key ID of the New Authentication Key for FIPS Compliance

This parameter specifies the key ID associated with the FIPS AK that you want the SED to apply to SED credentials other than the one that protects the data. When the value is not the MSID, these credentials are changed to the indicated AK, and other security-related items are set to conform to the FIPS certification requirements ("FIPS compliance mode") of the device. You may set the -fips-key-id to any one of the key
IDs known to the system. The FIPS key ID may, but does not have to, be the same as the data key ID parameter. Setting 
\textit{--fips-key-id} to the MSID key ID value disables FIPS compliance mode and restores the FIPS-related authorities and other components as required (other than data) to their default settings. The MSID is required when reverting to a version of Data ONTAP that does not manipulate the FIPS-compliance device components.

\textbf{Examples}

The following command changes both the AK and the power-cycle protection to values that protect the data at rest on the disk. Note that the \textit{--data-key-id} and \textit{--fips-key-id} parameters require one of the key IDs that appear in the output of the \textit{security key-manager query} command.

\begin{verbatim}
cluster1::> storage encryption disk modify --data-key-id 6A1E21D8000000010000000000000005A1E8F26FD68E76549C019F2350 --disk 2.10.*
Info: Starting modify on 14 disks.
View the status of the operation by using the storage encryption disk show-status command.
\end{verbatim}

The following command changes the FIPS AK and sets the device into FIPS-compliance mode. Note that the \textit{--fips-key-id} parameter requires one of the key IDs that appear in the output of the \textit{security key-manager query} command.

\begin{verbatim}
cluster1::> storage encryption disk modify --fips-key-id 6A1E21D8000000010000000000000005A1E8F26FD68E76549C019F2350 2.10.*
Info: Starting modify on 14 disks.
View the status of the operation by using the storage encryption disk show-status command.
\end{verbatim}

\textit{security key-manager create-key} on page 409

\textit{storage encryption disk revert-to-original-state}

Revert a self-encrypting disk to its original, as-manufactured state

\textbf{Availability}: This command is available to \textit{cluster} administrators at the \textit{admin} privilege level.

\textbf{Description}

Some self-encrypting disks (SEDs) are capable of an operation that restores them as much as possible to their as-manufactured state. The \textit{storage encryption disk revert-to-original-state} command invokes this special operation that is available only in SEDs that have the physical secure ID (PSID) printed on their labels.

The PSID is unique to each SED, meaning the command can revert only one SED at a time. The disk must be in a "broken" or "spare" state as show by the output of the \textit{storage disk show} command.

The command releases the cluster shell after launching the operation. Monitor the output of the \textit{storage encryption disk show-status} command for command completion.

Upon completion of the operation, all authentication keys (AKs) of the SED have been returned to the default manufacture secure ID (MSID), all data sanitized, the data band unlocked, and other vendor-unique encryption-related parameters reinitialized.
Parameters

-disk <disk path name> - Disk Name

The name of the SED to be reverted to its as-manufactured state. See storage disk modify for information about disk-naming conventions.

-psid <text> - Physical Secure ID

The PSID printed on the SED label.

Examples

The following command shows a SED being returned to its as-manufactured state:

```
cluster1::> storage encryption disk revert-to-original-state -disk 01.10.0 -psid AC65PYF8CG45YZABUQJKM98WV2VZGRLD
```

- storage disk show on page 761
- storage encryption disk show-status on page 797

storage encryption disk sanitize

Cryptographically sanitize a self-encrypting disk

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The storage encryption disk sanitize command cryptographically sanitizes one or more self-encrypting disks (SEDs), making the existing data on the SED impossible to retrieve. This operation employs the inherent erase capability of SEDs to perform all of the following changes:

- Changes the disk encryption key to a new random value
- Resets the power-on lock state to false
- Sets the data authentication key (AK) to the default manufacture secure ID (MSID).

There is no method to restore the disk encryption key to its previous value, meaning that you cannot recover the data on the SED. Use this command with extreme care.

The sanitize command requires you to enter a confirmation phrase before proceeding with the operation. The command releases the cluster shell after launching the operation. Monitor the output of the storage encryption disk show-status command for command completion.

Upon command completion, you may return the SED to service using the storage disk unfail command in advanced privilege mode. You might also need to reestablish ownership of the SED using the storage disk assign command.

Parameters

-disk <disk path name> - Disk Name

This parameter specifies the name of the SEDs you want to cryptographically sanitize. See the man page for the storage disk modify command for information about disk-naming conventions.

[-force-all-states [true]] - Sanitize All Matching Disks

When this parameter is false or not specified, the operation defaults to spare and broken disks only, as reported in the output of the storage disk show command. When you specify this parameter as true, it allows you to cryptographically sanitize all matching disk names regardless of their state, including those in active use in aggregates. This allows a quick erasure of all system data if you use -disk parameter with the
asterisk wildcard(*). If you sanitize active disks, the nodes might not be able to continue operation and halt or panic.

**Examples**

The following command sanitizes the disk 1.10.20:

```
cluster1::> storage encryption disk sanitize 1.10.20
Warning: This operation will cryptographically sanitize 1 spare or broken self-encrypting disk on 1 node.
       To continue, enter
       sanitize disk
       :sanitize disk

Info: Starting sanitize on 1 disk.
       View the status of the operation using the
       `storage encryption disk show-status` command.
```

If you do not enter the correct confirmation phrase, the operation is aborted:

```
cluster1::> storage encryption disk sanitize 1.10.2*
Warning: This operation will cryptographically sanitize 5 spare or broken self-encrypting disks on 1 node.
       To continue, enter
       sanitize disk
       :yes
No disks sanitized.
```

The following command quickly cryptographically sanitizes all system disks:

```
cluster1::> storage encryption disk sanitize -force-all-states -disk *
Warning: This operation will cryptographically sanitize 96 self-encrypting disks on 4 nodes.
       To continue, enter
       sanitize disk
       :sanitize disk

Info: Starting sanitize on 96 disks.
       View the status of the operation by using the
       `storage encryption disk show-status` command.
```

- `storage disk unfail` on page 778
- `storage disk assign` on page 751

**storage encryption disk show**

Display self-encrypting disk attributes

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.
**Description**
The `storage encryption disk show` command displays information about self-encrypting disks (SEDs). By default, the command displays the following information about all SEDs:

- Disk name
- The protection mode of the SED
- The key ID associated with the data authentication key (data AK)

You can use the following parameters together with the `-disk` parameter to narrow the selection of displayed SEDs or the information displayed about them.

**Parameters**
```
[-fields <fieldname>, ...]
```
If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

```
[-fips]
```
If you specify this parameter, the command displays the key ID associated with the FIPS-compliance authentication key ("FIPS AK") instead of the data key ID.

```
[-instance]
```
If you specify this parameter, the command displays detailed disk information about all disks, or only those specified by a `-disk` parameter.

```
[-disk <disk path name>] - Disk Name
```
If you specify this parameter, the command displays information about the specified disks. If you specify a single disk path name, then the output is the same as when you use the `-instance` parameter. See the man page for the `storage disk modify` command for information about disk-naming conventions. Default is all self-encrypting disks.

```
[-container-name <text>] - Container Name
```
This parameter specifies the container name associated with a SED. If you specify an aggregate name or other container name, then only the SEDs in that container are displayed. See the man page for the `storage disk show` command for a description of the container name. Use the `storage aggregate show-status` and `storage disk show` commands to determine which aggregates the SEDs are in.

```
[-data-key-id <text>] - Key ID of the Current Data Authentication Key
```
This parameter specifies the key ID associated with the data AK that the SED requires for authentication with the data-protection authorities in the SED. The special key ID 0x0 indicates that the current data AK of the SED is the default manufacture secure ID (MSID) that is not secret. To properly protect data at rest on the device, modify the data AK using a key ID that is not the MSID. When you modify the data AK with a non-MSID key ID, the system automatically sets the device's power-on lock enable control so that authentication with the data AK is required after a device power-cycle. Use `storage encryption disk modify -data-key-id key-id` to protect the data. Use `storage encryption disk modify -fips-key-id key-id` to place the SED into FIPS-compliance mode.

```
[-fips-key-id <text>] - Key ID of the Current FIPS Authentication Key
```
This parameter specifies the key ID associated with the FIPS authentication key ("FIPS AK") that the system must use to authenticate with FIPS-compliance authorities in the SED.

```
[-is-power-on-lock-enabled {true|false}] - Is Power-On Lock Protection Enabled?
```
This parameter specifies the state of the SED control that determines whether the SED requires authentication with the data AK after a power-cycle. The system enables this control parameter automatically when you use the `storage encryption disk modify -data-key-id` command to set the data AK to a value other than the MSID. Data is protected only when this parameter is `true` and the data AK is not the MSID. Compare with the values of the `-protection-mode` parameter below.
[-protection-mode <text>] - Mode of SED Data and FIPS-Compliance Protection

The protection mode that the SED is in:

- **open** - data is unprotected; SED is not in FIPS-compliance mode
- **data** - data is protected; SED is not in FIPS-compliance mode
- **part** - data is unprotected; SED is in FIPS-compliance mode
- **full** - data is protected; SED is in FIPS-compliance mode

**Examples**

The following command displays information about all SEDs:

```bash
cluster1::> storage encryption disk show
```

<table>
<thead>
<tr>
<th>Disk</th>
<th>Mode</th>
<th>Data Key ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.0.0</td>
<td>open</td>
<td>0x0</td>
</tr>
<tr>
<td>0.1.0</td>
<td>part</td>
<td>0x0</td>
</tr>
<tr>
<td>0.0.2</td>
<td>data</td>
<td>0A9C9FC00000000100000000000000000345CFD1BAD310CA8EDB377D439FB5C9A</td>
</tr>
<tr>
<td>1.10.0</td>
<td>open</td>
<td>0A53ED2A000000000001000000000000BEDC1B27AD3F0DB8891375AED2F34D0B</td>
</tr>
<tr>
<td>1.10.1</td>
<td>part</td>
<td>0A9C9FC00000000100000000000000000345CFD1BAD310CA8EDB377D439FB5C9A</td>
</tr>
<tr>
<td>1.10.2</td>
<td>full</td>
<td>0A9C9FC00000000100000000000000000345CFD1BAD310CA8EDB377D439FB5C9A</td>
</tr>
</tbody>
</table>

Note in the example that only disk 1.10.2 is fully protected with FIPS mode, power-on-lock enable, and an AK that is not the default MSID.

The following command displays information about the protection mode and FIPS key ID for all SEDs:

```bash
cluster1::> storage encryption disk show -fips
```

<table>
<thead>
<tr>
<th>Disk</th>
<th>Mode</th>
<th>FIPS-Compliance Key ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.0.0</td>

</table>

Note again that only disk 1.10.2 is fully protected with FIPS-compliance mode set, power-on-lock enabled, and a data AK that is not the default MSID.

The following command displays the individual fields for disk 1.10.1:

```bash
cluster1::> storage encryption disk show -disk 1.10.1
```

Disk Name: 1.10.1

- Key ID of the Current Data Authentication Key: 0A9C9FC00000000100000000000000000345CFD1BAD310CA8EDB377D439FB5C9A
- Key ID of the Current FIPS Authentication Key: 0A9C9FC00000000100000000000000000345CFD1BAD310CA8EDB377D439FB5C9A
- Is Power-On Lock Protection Enabled?: true
- Mode of SED Data and FIPS-Compliance Protection: open

storage encryption disk show-status

Display status of disk encryption operation

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The storage encryption disk show-status command displays the results of the latest destroy, modify, or sanitize operation of the storage encryption disk command family. Use this command to view the progress of these operations on self-encrypting disks (SEDs).

Parameters

{[-fields <fieldname>, ...]
   If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.
[-instance ]
   If you specify the -instance parameter, the command displays detailed information about all fields.
[-node <nodename>] - Node Name
   If you specify this parameter, the command displays disk encryption status for the nodes that match this parameter.
[-is-sed-support {true|false}] - Node Supports Self-Encrypting Disks
   If you specify this parameter, the command displays disk encryption status for the nodes that match this parameter (true means the node supports SEDs).
[-latest-op <Storage Disk Encryption Operation>] - Latest Operation Requested
   If you specify this parameter, the command displays disk encryption status for the nodes with a most recent storage encryption disk operation that matches this parameter (one of destroy, modify, revert-to-original-state, sanitize, or unknown).
[-op-start-time <MM/DD/YYYY HH:MM:SS>] - Operation Start Time
   Selects the nodes with operation start times that match this parameter.
[-op-execute-time <integer>] - Execution Time in Seconds
   If you specify this parameter, the command displays disk encryption status for the nodes with operation execution time that matches this parameter. The operation may be partial or completed.
[-disk-start-count <integer>] - Number of Disks Started
   If you specify this parameter, the command displays disk encryption status for the nodes that started this number of SEDs in their latest operation.
[-disk-done-count <integer>] - Number of Disks Done
   Selects the nodes that report this number of SEDs having completed the latest operation, successfully or not.
[-disk-success-count <integer>] - Number of Disks Successful
   If you specify this parameter, the command displays disk encryption status for the nodes that report this number of SEDs that successfully completed the latest operation. When the operation is finished, if the success count is not the same as the started count, some additional detail is available using the -instance or -node parameters.
[-disk-no-key-id-count <integer>] - Number of Disks with Key ID Not Found
   If you specify this parameter, the command displays disk encryption status for the nodes that report this number of SEDs that failed the latest operation because Data ONTAP could not find the Key IDs associated with the required authentication key of the SED.
[-disk-no-authent-count <integer>] - Number of Disks Not Authenticated

If you specify this parameter, the command displays disk encryption status for the nodes that report this number of SEDs that failed the latest operation because the identified Authentication Key could not authenticate with the SED.

Examples

When no operation has been requested since node boot, the status for that node is empty. If you enter a node name, the output is in the same format as for the -instance parameter.

```
class::> storage encryption disk show-status -node node
   Node Name: node
   Node Supports Self-Encrypting Disks: true
   Latest Operation Requested: unknown
   Operation Start Time: -
   Execution Time in Seconds: -
   Number of Disks Started: -
   Number of Disks Done: -
   Number of Disks Successful: -
   Number of Disks with Key ID Not Found: -
   Number of Disks Not Authenticated: -
```

Once an operation begins, the status is dynamic until all devices have completed. When disks are modified, sanitized, or destroyed, sequential executions of `storage encryption disk show-status` appear as in this example that shows the progress of a modify operation on three SEDs on each node of a two-node cluster:

```
class::> storage encryption disk show-status
  SED                  Latest  Start             Execution  Disks  Disks  Disk
  Node     Support Request Timestamp          Time (sec) Begun   Done Successful
  -------  ------- -------- ------------------ ---------- ------ ------ ----------
  node     true    modify   9/22/2014 13:58:53          4      3      0          0
  node1    true    modify   9/22/2014 13:58:53          4      3      0          0
```

```
class::> storage encryption disk show-status
  SED                  Latest  Start             Execution  Disks  Disks  Disk
  Node     Support Request Timestamp          Time (sec) Begun   Done Successful
  -------  ------- -------- ------------------ ---------- ------ ------ ----------
  node     true    modify   9/22/2014 13:58:53          7      3      3          3
  node1    true    modify   9/22/2014 13:58:53          7      3      3          3
```

storage errors commands

The errors directory

storage errors show

Display storage configuration errors.

Availability: This command is available to cluster administrators at the admin privilege level.
Description
The `storage errors show` command displays configuration errors with back end storage arrays.

Parameters

{ [-fields <fieldname>, ...] }  
If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

[ [-instance] ]  
If you specify the `-instance` parameter, the command displays detailed information about all fields.

[ [-uid <text>] ] - UID  
Selects the disks that match this parameter value.

[ [-array-name <array name>] ] - Array Name  
Selects the disks that have the specified name for the storage array that is connected to the cluster.

[ [-node <nodename]|local] ] - Controller Name  
Selects the disks that match this parameter value.

[ [-disk <disk path name>] ] - Disk  
Selects the disks that match this parameter value.

[ [-serial-number <text>] ] - Serial Number  
Selects the disks that match this parameter value.

[ [-error-id <integer>, ...] ] - Error ID  
Selects the disks with error-id values that match this parameter value.

[ [-error-type {onepath|onedomain|control|foreign|toobig|toosmall|invalidblocksize|targetasymmap|deviceasymmap|failovermisconfig|unknown|netapp|fwdownrev|qualfail|diskfail|notallflashdisk}, ...] ] - Error Type  
Selects the disks with error types values that match this parameter value.

Examples

The following example displays configuration errors seen in the system:

```
cluster1:/> storage errors show
------------------------
vnvci9124s54:1-24.126L23 (600a0b800019e999000036b24bac3983): This array LUN reports an invalid block size and is not usable. Only a block size of 512 is supported.
```

storage failover commands

Manage storage failover

This contains commands to display and modify storage failover related options of a node.

storage failover giveback

Return failed-over storage to its home node

Availability: This command is available to `cluster` administrators at the `admin` privilege level.
Description
The `storage failover giveback` command returns storage that has failed over to a node's partner back to the home node. This operation fails if other resource-intensive operations (for instance, system dumps) are running and make the giveback operation potentially dangerous or disruptive. Some options are available only at the advanced privilege level and higher. Run the `storage failover show-giveback` command to check the status of giveback operations.

Note:
- If the system ID of the partner has changed while the node is in takeover mode, the `storage failover giveback` command updates the ownership of the partner's disks to the new system ID while giving back.
- If the giveback operation fails due to the operation being vetoed by a subsystem, check the syslog or EMS output for a subsystem-specific reason for the abort. The corrective action is subsystem-specific and is detailed in the corrective action portion of the message. Follow the corrective action specified by the subsystem and then reissue the `storage failover giveback` command. If you cannot perform the corrective action, then use the `override-vetoes` option in the `storage failover giveback` command to force the giveback.
- If the giveback operation fails because the node cannot communicate with its partner, check the EMS output for the corrective action. Follow the corrective action and then reissue the `storage failover giveback` command. If you cannot perform the corrective action, then use the `-require-partner-waiting false` option in the `storage failover giveback` command to force the giveback. This parameter is available only at the advanced privilege level and higher.
- If the node does not receive notification that the partner has brought online the given-back aggregate and its volumes, the `storage failover show-giveback` command displays the giveback status for the aggregate as failed. A possible reason for this failure is that the partner is overloaded and slow in bringing the aggregate online. Run the `storage aggregate show` command to verify that the aggregate and its volumes are online on the partner node. The node will not attempt the giveback operation for remaining aggregates. To force the giveback, use the `-require-partner-waiting false` option in the `storage failover giveback` command. This parameter is available only at the advanced privilege level and higher.

Parameters

`{ -ofnode {<nodename>|local} - Node to which Control is Givenback
  Specifies the node whose storage is currently taken over by its partner and will be given back by the giveback operation.}

{ -fromnode {<nodename>|local} - Node Initiating Giveback
  Specifies the node that currently holds the storage that is to be returned to the partner node.}

[-require-partner-waiting {true|false}] - Require Partner in Waiting (privilege: advanced)
  If this optional parameter is used and set to false, the storage is given back regardless of whether the partner node is available to take back the storage or not. If this parameter is used and set to true, the storage will not be given back if the partner node is not available to take back the storage. If this parameter is not used, the behavior defaults to the setting of the `-check-partner` option set with the `storage failover modify` command.

[-override-vetoes {true}] - Override All Vetoes
  If this optional parameter is used, the system overrides veto votes during a giveback operation. If this parameter is not used, the system does not proceed with a giveback if it is vetoed. This parameter, if used, can only be set to true.

[-only-cfo-aggregates {true}] - Giveback Only CFO Aggregates
  If this optional parameter is used, giveback of only the CFO aggregates (root aggregate and CFO style data aggregates) will be attempted. If this parameter is not used, giveback of all the aggregates (CFO and SFO aggregates) will be attempted. This parameter, if used, can only be set to true.
Examples
The following example gives back storage that is currently held by a node named node1. The partner must be available for the giveback operation to occur.

```
node::> storage failover giveback -fromnode node1
```

The following example gives back only the CFO aggregates to a node named node2 (the aggregates are currently held by a node named node1). The partner must be available for the giveback operation to occur, and the veto-giveback process can be overridden.

```
node::> storage failover giveback -ofnode node2
    -override-vetoes true -only-cfo-aggregates true
```

**storage failover modify**
Modify storage failover attributes

**Availability:** This command is available to cluster administrators at the `admin` privilege level.

**Description**
The `storage failover modify` command changes the storage-failover options for a node. Some options are available only at the advanced privilege level and higher.

**Parameters**
- `--node {<nodename> | local}` - Node
  This specifies the node whose storage-failover options are to be modified.
  
  `{ [-enabled {true|false}] - Takeover Enabled
  This optionally specifies whether storage failover is enabled. The default setting is `true`.

  | [-mode {ha|non_ha}] - HA Mode
  This specifies whether the node is set up in high-availability mode or stand-alone mode. If the node is a member of a high-availability configuration, set the value to `ha`. If the node is stand-alone, set the value to `non_ha`. Before setting the HA mode, you must complete the platform dependent steps to set up the system in a stand-alone or HA configuration as shown in the documentation for your platform.

  [-auto-giveback {true|false}] - Auto Giveback Enabled
  This optionally specifies whether automatic giveback operations are enabled. An automatic giveback operation is invoked when one node of a failover pair is in takeover mode and the failed node is repaired and restarts. When the repaired node boots, the node in takeover mode detects this and initiates a giveback operation. The default setting is `false`, except for two-node clusters where the default setting is `true`.

  [-check-partner {true|false}] - Check Partner Enabled
  This optionally specifies whether the node checks its partner’s readiness before initiating a giveback operation when the `storage failover giveback` command is run. The default setting is `true`, which reduces downtime caused by a giveback operation.
[-detection-time <integer>] - Takeover Detection Time (secs)
   This optionally specifies the amount of time, in seconds, that a node remains unresponsive before its partner
   initiates a takeover operation. Possible values range from 10 to 180 seconds. The default setting is 15 seconds.

[-onfailure {true|false}] - Takeover on Failure Enabled (privilege: advanced)
   This optionally specifies whether the node automatically takes over for its partner node if the partner node
   fails. The default setting is true. This parameter is available only at the advanced privilege level and higher.

[-onpanic {true|false}] - Takeover on Panic Enabled
   This optionally specifies whether the node automatically takes over for its partner node if the partner node
   panics. The default setting is true. Changing this parameter on one node automatically makes the same
   change on its partner node.

[-onshort-uptime {true|false}] - Takeover on Short Uptime Enabled (privilege: advanced)
   This optionally specifies whether the node takes over for its partner node if the partner node fails within 60
   seconds of starting up; the time period is modifiable by using the -short-uptime parameter. The default
   setting is true. This parameter is available only at the advanced privilege level and higher.

[-short-uptime <integer>] - Short Uptime (secs) (privilege: advanced)
   This optionally specifies the time period used by the -onshort-uptime parameter. The default setting is 60
   seconds. This parameter is available only at the advanced privilege level and higher.

[-attempts <integer>] - Number of Giveback Attempts (privilege: advanced)
   This optionally specifies the number of times the node attempts an automatic giveback operation within 60
   minutes; the time period is modifiable by using the -attempts-time parameter. The default setting is 2
   attempts. This parameter is available only at the advanced privilege level and higher.

[-attempts-time <integer>] - Giveback Attempts Period (minutes) (privilege: advanced)
   This optionally specifies the time period used by the -attempts parameter. The default setting is 60 minutes.
   This parameter is available only at the advanced privilege level and higher.

[-propagate {true|false}] - Propagate Status via Mailbox (privilege: advanced)
   This optionally specifies whether storage-failover status is communicated via mailbox disks. The default
   setting is true. This parameter is available only at the advanced privilege level and higher.

[-read-interval <integer>] - Node Status Read Interval (secs) (privilege: advanced)
   This optionally specifies, in seconds, how frequently the node reads its partner node's status from the mailbox
   disks. The default setting is 5 seconds. This parameter is available only at the advanced privilege level and
   higher.

[-write-interval <integer>] - Node Status Write Interval (secs) (privilege: advanced)
   This optionally specifies, in seconds, how frequently the node writes its status to the mailbox disks. The
   default setting is 5 seconds. This parameter is available only at the advanced privilege level and higher.

[-onreboot {true|false}] - Takeover on Reboot Enabled
   This optionally specifies whether the node automatically takes over for its partner if the partner reboots. The
   default setting is true. Takeover can occur if the partner exceeds the expected time to reboot even when this
   option is set to false. The expected time to reboot is different for different platforms. The minimum expected
   time to reboot is 180 seconds. The -inhibit-takeover option of the system node reboot command overrides this option: if a node is rebooted with -inhibit-takeover set to true then takeover does not occur, even if the takeover on reboot option is true. If a node does takeover due to the partner rebooting, then it will automatically giveback after the reboot, even if the -auto-giveback option is set to false. This is non-persistent behavior: if the node does takeover due to partner reboot and then itself reboots (prior to giveback) then it will not automatically giveback if the -auto-giveback option is set to false.

[-delay-seconds <integer>] - Delay Before Auto Giveback (secs)
   This optionally specifies the minimum time that a node will stay in takeover state prior to performing an
   automatic giveback. If the taken over node recovers quickly (for example, if the takeover was due to a reboot),
by delaying the giveback for a few minutes the outage during the takeover and giveback can be reduced to two
short outages instead of one longer one. The allowed range is 0 to 600, inclusive. The default setting is 600
seconds. This option affects all types of auto-giveback. This parameter is available only at the advanced
privilege level and higher.

**Note:** This delay does not affect manual giveback.

```
[-hwassist {true|false}] - Hardware Assist Enabled
```

This optionally specifies whether the hardware assist feature is enabled. If set to `true` this feature helps in fast
takeover detection times in certain cases.

```
[-hwassist-partner-ip <IP Address>] - Partner's Hwassist IP
```

This optionally specifies the Ip address on which the partner node receives hardware assist alerts. For the
hardware assist feature to be active, the value of this option should be equal to partner's node management IP
address.

```
[-hwassist-partner-port <integer>] - Partner's Hwassist Port
```

This optionally specifies the port number on which partner node listens to hardware assist alerts. It is
recommended to have this value to be between 4000-4500. The default value is 4444.

```
[-hwassist-health-check-interval <integer>] - Hwassist Health Check Interval (secs)
```

This optionally specifies, in seconds, how frequently the hardware assist hardware on a node sends a heartbeat
to its partner. The default value is 180.

```
[-hwassist-retry-count <integer>] - Hwassist Retry Count
```

This optionally specifies the number of times we repeat sending an hardware assist alert. The default value is
2.

```
[-auto-giveback-after-panic {true|false}] - Auto Giveback After Takeover On Panic
```

This optionally specifies whether a node should attempt automatic giveback operations if takeover was
because of a disruption in the partner's operation. An automatic giveback operation is invoked when one node
of a failover pair is in takeover mode and the failed node is repaired and restarts. When the repaired node
boots, the node in takeover mode detects this and initiates a giveback operation automatically. The default
setting is `true`.

```
[-bypass-takeover-optimization {true|false}] - Bypass Takeover Optimization Enabled
```

This optionally specifies whether operator-initiated planned takeovers will be optimized. If the option is set to
true, the takeover optimization will be bypassed. If the option is set to false, the operator-initiated planned
takeover will be optimized. If the planned takeover is optimized, then all SFO aggregates will be relocated
serially to the node that is taking over, prior to takeover. This reduces client outage. The default value for this
option is false.

```
[-aggregate-migration-timeout <integer>] - Aggregate Migration Timeout (secs) (privilege: advanced)
```

This optionally specifies the amount of time, in seconds, the source node has to wait for the destination node
to complete the aggregate migration before declaring the migration as failed. The default setting is 120
seconds.

```
[-auto-giveback-override-vetoes {true|false}] - Auto-giveback Override Vetoes Enabled
```

This optionally specifies whether long-running operations (for instance, NDMP dump/restoration, volume
verification, etc.) are terminated and partner veto votes are overridden when an automatic giveback operation is
initiated. When this option is set to false, the automatic giveback operation is deferred until the long-running
operations have completed and will also take into consideration partner veto votes. The default setting is
`false`.

```
[-auto-giveback-cifs-terminate-minutes <integer>] - Auto Giveback Delay Before Terminating CIFS
(minutes)
```

This option can be used to specify the number of minutes to delay an automatic giveback before terminating
CIFS clients that have open files. During the delay, the system periodically sends notices to the affected
workstations. If 0 (zero) minutes are specified, then CIFS clients will be terminated immediately.
Examples
The following example enables the storage-failover service on a node named node0:

```
node::> storage failover modify -node node0 -enabled true
```

The following examples enable storage-failover takeover on a short uptime of 30 seconds on a node named node0:

```
node::*> storage failover modify -node node0 -onshort-uptime true -short-uptime 30
```

storage failover show
Display storage failover status

Availability: This command is available to `cluster` administrators at the `admin` privilege level.

Description
The `storage failover show` command displays information about storage-failover configurations. By default, the command displays the following information:

- Node name.
- Partner node name.
- Whether storage failover is possible.
- The current state of storage failover. If the takeover is disabled the appropriate reason would be displayed.

To display detailed information about storage failover on a specific node, run the command with the -node parameter. The detailed view adds the following information:

- Node NVRAM ID.
- Partner NVRAM ID.
- Whether storage failover is enabled.
- Whether the storage-failover interconnect is available.
- Status of individual storage-failover interconnect links.
- Type and vendor of the storage-failover interconnect.
- Partner State
- Status codes from the takeover-by-partner process. Possible values include:
  - NVRAM_DOWN
  - OPERATOR_DISABLE_NVRAM
  - PARTNER_RESET
  - FM_TAKEOVER
  - NVRAM_MISMATCH
• OPERATOR_DENY
• CLUSTER_DISABLE
• VERSION
• SHELFF_HOT
• REVERT_IN_PROGRESS
• HALT_NOTKOVER
• TAKEOVER_ON_PANIC

• Reasons why takeover is not possible, if applicable. Possible values include:
  • NOT_INIT
  • DISABLED
  • DEGRADED
  • MBX_UNKNOWN
  • FM_VERSION
  • PARTNER_DISABLED
  • OPERATOR_DENY
  • NVRAM_MISMATCH
  • VERSION
  • IC_ERROR
  • BOOTING
  • SHELFF_HOT
  • PARTNER_REVERT_IN_PROGRESS
  • LOCAL_REVERT_IN_PROGRESS
  • PARTNER_TAKEOVER
  • LOCAL_TAKEOVER
  • HALT_NOTKOVER
  • LOG_UNSINC
  • UNKNOWN
  • WAITING_FOR_PARTNER
  • LOW_MEMORY
  • HALTING
  • MBX_UNCERTAIN
  • NO_AUTO_TKOVER

• Time until takeover, in seconds.
• Time until auto giveback, in seconds.
• Delay for auto giveback, in seconds.
• List of local mailbox disks.
• List of partner mailbox disks.
• Whether operator-initiated planned takeover will be optimized for performance by relocating SFO (non-root) aggregates serially to the partner prior to takeover.

You can specify additional parameters to select the displayed information. For example, to display information only about storage-failover configurations whose interconnect is down, run the command with `-interconnect-up false`.

Parameters

`[-fields <fieldname>, ...]`

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

`[-options]`

Displays the following information:

• Node name
• Whether automatic giveback operations are enabled
• Whether long-running operations are terminated when an automatic giveback operation is initiated
• Whether the node checks its partner's readiness before initiating a giveback operation
• The time, in seconds, that the node remains unresponsive before its partner initiates a takeover operation
• Whether the node automatically takes over for its partner if the partner fails
• Whether the node automatically takes over for its partner if the partner panics
• Whether the node automatically takes over for its partner if the partner reboots
• whether Hardware Assisted Takeover is enabled
• Ip address on which the partner node listens to the Hardware Assist alerts
• Port number on which the partner node listens to the Hardware Assist alerts
• Whether operator-initiated planned takeover will be optimized for performance by relocating SFO (non-root) aggregates serially to the partner prior to takeover

If this parameter is specified when the privilege level is set to advanced or higher, the command displays the information in the previous list and the following additional information:

• Whether the node takes over for its partner if its partner fails after a period of time, which is listed in the following field
• The number of seconds before the node takes over for its partner
• The number of times the node attempts an automatic giveback operation within a period of time
• The number of minutes in which the automatic giveback attempts can occur
• Whether storage-failover status is communicated via mailbox disks
• The interval at which the node reads its partner node's status from the mailbox disks
• The interval at which the node writes its status to the mailbox disks
• The interval at which Hardware assist h/w sends a heartbeat
• The number of times the Hardware assist alert is sent

| [-takeover-status ]
| Displays the following information:
| • Node name
| • Partner name
| • Takeover enabled
| • Takeover possible
| • Interconnect up
| • State
| • Node NVRAM ID
| • Partner NVRAM ID
| • Reason Takeover Not Possible By Partner
| • Reason Takeover Not Possible
| • Time Until Takeover

| [-advanced ] (privilege: advanced)
| Displays the following information:
| • Node name
| • Whether kill messages are issued during a takeover operation
| • Whether the node controls its partner's storage aggregates
| • The time when firmware notification was received
| • The time when booting notification was received
| • The time at which the last takeover or giveback operation occurred, in microseconds
| • The number of times the failover log was unsynchronized

| [-iotime ] (privilege: advanced)
| Displays the following information:
| • Node name
| • Primary normal I/O time
| • Primary transition I/O time
| • Backup normal I/O time
| • Backup transition I/O time

| [-mailbox-status ] (privilege: advanced)
| Displays the following information:
| • Node name
| • Primary mailbox status
| • Backup mailbox status
[-more-options ] (privilege: advanced)

Displays the following information:

- Node name
- Whether takeover on short uptime is enabled
- Short uptime, in seconds
- Number of giveback attempts
- Interval of giveback attempts, in minutes
- Whether the primary mailbox is online
- Mailbox status read interval, in seconds
- Mailbox status write interval, in seconds

[-progress ] (privilege: advanced)

Displays the following information:

- Node name
- Maximum resource-table index number
- Current resource-table index number
- Current resource-table entry

[-timeout ] (privilege: advanced)

Displays the following information:

- Node name
- Fast timeout
- Slow timeout
- Mailbox timeout
- Connection timeout
- Operator timeout
- Firmware timeout
- Dump-core timeout
- Booting timeout
- Reboot timeout

[-transit ] (privilege: advanced)

Displays the following information:

- Node name
- Transit Timer Enabled
- Transit Timeout

[-instance ]

If you specify the -instance parameter, the command displays detailed information about all fields.
[-node \{<nodename>|local\}] - Node
Selects the nodes whose name matches this parameter value.

[-partner-name <text>] - Partner Name
Selects the nodes that have the specified partner-name setting.

[-nvramid <integer>] - Node NVRAM ID
Selects the nodes that have the specified NVRAM ID setting.

[-partner-nvramid <integer>] - Partner NVRAM ID
Selects the nodes that have the specified partner NVRAM ID setting.

[-enabled {true|false}] - Takeover Enabled
Selects the nodes that have the specified takeover-enabled setting.

[-mode {ha|non_ha}] - HA Mode
Selects the nodes that have the specified HA-mode setting. If the value is set to ha then the node is a member of a storage-failover configuration. If it is set to non-ha then it is in a stand alone configuration.

[-possible {true|false}] - Takeover Possible
Selects the nodes that have the specified failover-possible setting.

[-reason <text>, ...] - Reason Takeover not Possible
Selects the nodes that have the specified reason-not-possible setting. Possible values include:

- NOT_INIT
- DISABLED
- DEGRADED
- MBX_UNKNOWN
- FM_VERSION
- PARTNER.Disabled
- OPERATOR_DENY
- NVRAM_MISMATCH
- VERSION
- IC_ERROR
- BOOTING
- SHELF_HOT
- PARTNER_REVERT_IN_PROGRESS
- LOCAL_REVERT_IN_PROGRESS
- PARTNER_TAKEOVER
- LOCAL_TAKEOVER
- HALT_NOTKOVER
- LOG_UNSYNC
- UNKNOWN
- WAITING_FOR_PARTNER
- LOW_MEMORY
- HALTING
- MBX_UNCERTAIN
- NO_AUTO_TKOVER

[-interconnect-up (true|false)] - Interconnect Up
Selects the nodes that have the specified interconnect-up setting.

[-interconnect-links <text>] - Interconnect Links
Selects the nodes that have the specified interconnect-links setting.

[-interconnect-type <text>] - Interconnect Type
Selects the nodes that have the specified interconnect-type setting.

[-state-description <text>] - State Description
Selects the nodes that have the specified state-description setting.

[-partner-state <text>] - Partner State
Selects the nodes that have the specified partner-state setting. Possible values include:
- OPERATOR COMPLETED
- DEBUGGUER COMPLETED
- PROGRESS COUNTER
- I/O ERROR
- BAD CHECKSUM
- RESERVED
- UNKNOWN
- INITIALIZING
- IN POWER-ON SELF TEST
- BOOTING
- BOOT FAILED
- WAITING
- KERNEL LOADED
- UP
- IN DEBUGGER
- WAITING FOR OPERATOR INPUT
- DUMPING CORE
- HALTED
- REBOOTING
- WAITING FOR GIVEBACK (DISK RESERVATIONS)
- WAITING FOR GIVEBACK (HA MAILBOXES)
• DUMPING SPARECORE
• MULTI-DISK PANIC
• IN TAKEOVER

[-time-until-takeover <integer>] - Time Until Takeover
Selects the nodes that have the specified time-until-takeover setting.

[-partner-reason <text>, ...] - Reason Takeover not Possible by Partner
Selects the nodes that have the specified partner-reason text setting.

[-killpackets {true|false}] - Issue Kill Packets (privilege: advanced)
Selects the nodes that have the specified kill packets setting.

[-partner-aggregates {true|false}] - Control Partner Aggregates (privilege: advanced)
Selects the nodes that have the specified partner aggregates setting.

[-current-index <integer>] - Current Progress Index (privilege: advanced)
Selects the nodes that have the specified current-progress index setting.

[-current-entry <text>] - Current Progress Entry (privilege: advanced)
Selects the nodes that have the specified current-progress entry setting.

[-maximum-index <integer>] - Maximum Progress Index (privilege: advanced)
Selects the nodes that have the specified maximum-progress index setting.

[-pmbox-status <text>, ...] - Primary Mailbox Status (privilege: advanced)
Selects the nodes that have the specified primary mailbox status setting. Possible values include:
• MBX_STATUS_NODISKS
• MBX_STATUS_UNCERTAIN
• MBX_STATUS_STALE
• MBX_STATUS_CONFLICTED
• MBX_STATUS_OLD_VERSION
• MBX_STATUS_NOT_FOUND
• MBX_STATUS_WRONG_STATE
• MBX_STATUS_BACKUP

[-bmbox-status <text>, ...] - Backup Mailbox Status (privilege: advanced)
Selects the nodes that have the specified backup-mailbox status setting. See the description of the -pmbox-status parameter for a list of possible values.

[-major-seq-num-local <integer>] - Local Major Sequence Number (privilege: advanced)
Selects the nodes that have the specified mailbox heartbeat major sequence number on the local node.

[-minor-seq-num-local <integer>] - Local Minor Sequence Number (privilege: advanced)
Selects the nodes that have the specified mailbox heartbeat minor sequence number on the local node.

[-major-seq-num-partner <integer>] - Partner Major Sequence Number (privilege: advanced)
Selects the nodes that have the specified mailbox heartbeat major sequence number on the partner node.

[-minor-seq-num-partner <integer>] - Partner Minor Sequence Number (privilege: advanced)
Selects the nodes that have the specified mailbox heartbeat minor sequence number on the partner node.
[-local-mbx-node-status <Mailbox Status>] - Local Mailbox Node Status (privilege: advanced)
Selects the nodes that have the specified local mailbox node status. Possible values include:
- MBX_UNKNOWN - Local node is up, mailbox uninitialized
- MBX_TAKEOVER_DISABLED - Local node is up but takeover is disallowed
- MBX_TAKEOVER_ENABLED - Local node is up and takeover is allowed
- MBX_TAKEOVER_ACTIVE - Partner node has taken over
- MBX_GIVEBACK_DONE - Giveback completed, but local node has not yet restarted

[-mbx-abs-time-local <integer>] - Local Mailbox Absolute Time (privilege: advanced)
Selects the nodes that have the specified local mailbox channel absolute time. This time is measured in msecs since 1/1/1970 (epoch).

[-mbx-sk-time-local <integer>] - Local Mailbox Kernel Time (privilege: advanced)
Selects the nodes that have the specified local mailbox channel Kernel Time.

[-mbx-sk-cycles-local <integer>] - Local Mailbox CPU Cycles (privilege: advanced)
Selects the nodes that have the specified local mailbox channel CPU Cycle count.

[-ic-abs-time-local <integer>] - Local IC Absolute Time (privilege: advanced)
Selects the nodes that have the specified local Interconnect channel absolute time. This time is measured in msecs since 1/1/1970 (epoch).

[-ic-sk-time-local <integer>] - Local IC Kernel Time (privilege: advanced)
Selects the nodes that have the specified local Interconnect channel Kernel Time.

[-ic-sk-cycles-local <integer>] - Local IC CPU Cycles (privilege: advanced)
Selects the nodes that have the specified local Interconnect channel CPU Cycle count.

[-partner-mbx-node-status <Mailbox Status>] - Partner Mailbox Node Status (privilege: advanced)
Selects the nodes that have the specified partner mailbox node status. Possible values include:
- MBX_UNKNOWN
- MBX_TAKEOVER_DISABLED
- MBX_TAKEOVER_ENABLED
- MBX_TAKEOVER_ACTIVE
- MBX_GIVEBACK_DONE

[-mbx-abs-time-partner <integer>] - Partner Mailbox Absolute Time (privilege: advanced)
Selects the nodes that have the specified partner mailbox channel absolute time. This time is measured in msecs since 1/1/1970 (epoch).

[-mbx-sk-time-partner <integer>] - Partner Mailbox Kernel Time (privilege: advanced)
Selects the nodes that have the specified partner mailbox channel Kernel Time.

[-mbx-sk-cycles-partner <integer>] - Partner Mailbox CPU Cycles (privilege: advanced)
Selects the nodes that have the specified partner mailbox channel CPU Cycle count.

[-mbx-major-seq-num-partner <integer>] - Partner Mailbox Major Sequence Number (privilege: advanced)
Selects the nodes that have the specified partner mailbox channel major sequence number.

[-mbx-minor-seq-num-partner <integer>] - Partner Mailbox Minor Sequence Number (privilege: advanced)
Selects the nodes that have the specified partner mailbox channel minor sequence number.
[-ic-abs-time-partner <integer>] - Partner IC Absolute Time (privilege: advanced)
Selects the nodes that have the specified partner Interconnect channel absolute time. This time is measured in msecs since 1/1/1970 (epoch).

[-ic-sk-time-partner <integer>] - Partner IC Kernel Time (privilege: advanced)
Selects the nodes that have the specified partner Interconnect channel Kernel Time.

[-ic-sk-cycles-partner <integer>] - Partner IC CPU Cycles (privilege: advanced)
Selects the nodes that have the specified partner Interconnect channel CPU Cycle count.

[-ic-major-seq-num-partner <integer>] - Partner IC Major Sequence Number (privilege: advanced)
Selects the nodes that have the specified partner Interconnect channel major sequence number.

[-ic-minor-seq-num-partner <integer>] - Partner IC Minor Sequence Number (privilege: advanced)
Selects the nodes that have the specified partner Interconnect channel minor sequence number.

[-local-takeover-info <text>] - Local Takeover Info (privilege: advanced)
Selects the nodes that have the specified local node takeover information. This includes the type of negotiated failover request, or if takeover is not possible, the reason why takeover is disabled. Possible values include:

- NOTKOVER_NVRAM_DOWN - NVRAM mirror is down
- NOTKOVER_OPERATOR_DISABLE_NVRAM - Operator disabled
- NOTKOVER_PARTNER_RESET - A link reset is in progress
- NOTKOVER_FM_TAKEOVER - The failover monitor has declared takeover
- NOTKOVER_NVRAM_MISMATCH - NVRAM sizes mismatch
- NOTKOVER_OPERATOR_DENY - Operator denies takeover
- NOTKOVER_CLUSTER_DISABLE - Cluster is disabled
- NOTKOVER_VERSION - Version mismatch
- NOTKOVER_SHELF_HOT - Disk shelf is too hot
- NOTKOVER_REVERT_IN_PROGESS - Revert is in progress
- NOTKOVER_HALAT_NOTKOVER - Node halted in no-takeover mode
- TKOVER_ON_REBOOT - Enable takeover on reboot
- TKOVER_ON_PANIC - Enabled takeover on panic
- TKOVER_ON_STUTTER_DISABLED - Disable takeover on short uptime
- NFO_DISK_SHELF_ENABLED - Negotiated failover for disk shelf module is enabled
- NFO_ISCSI_ENABLED - Negotiated failover for network interfaces module is enabled
- NFO_FCP_TARGET_ENABLED - Negotiated failover for fcp target module is enabled

[-partner-takeover-info <text>] - Partner Takeover Info (privilege: advanced)
Selects the nodes that have the specified partner node takeover information. This includes the type of negotiated failover request, or if takeover is not possible, the reason why takeover is disabled. Possible values include:

- NOTKOVER_NVRAM_DOWN - NVRAM mirror is down
- NOTKOVER_OPERATOR_DISABLE_NVRAM - Operator disabled
- NOTKOVER_PARTNER_RESET - A link reset is in progress
• NOTKOVER_FM_TAKEOVER - The failover monitor has declared takeover
• NOTKOVER_NVRAM_MISMATCH - NVRAM sizes mismatch
• NOTKOVER_OPERATOR_DENY - Operator denies takeover
• NOTKOVER_CLUSTER_DISABLE - Cluster is disabled
• NOTKOVER_VERSION - Version mismatch
• NOTKOVER_SHELF_HOT - Disk shelf is too hot
• NOTKOVER_REVERT_IN_PROGRESS - Revert is in progress
• NOTKOVER_HALT_NOTKOVER - Node halted in no-takeover mode
• TKOVER_ON_REBOOT - Takeover on reboot is enabled
• TKOVER_ON_PANIC - Takeover on panic is enabled
• TKOVER_ON_STUTTER_DISABLED - Disable takeover on short uptime
• NFO_DISK_SHELF_ENABLED - Negotiated failover for disk shelf module is enabled
• NFO_ISCSI_ENABLED - Negotiated failover for network interfaces module is enabled
• NFO_FCP_TARGET_ENABLED - Negotiated failover for fcp target module is enabled

[-local-headswap-state <Headswap State>] - Local Head Swap State (privilege: advanced)
Selects the nodes that have the specified local node headswap state. Possible values are:
• HEADSWAP_NONE - head swap not in progress
• HEADSWAP_START - head swap started
• HEADSWAP_CFO_START - CFO phase of head swap started
• HEADSWAP_CFO_END - CFO phase of head swap completed
• HEADSWAP_SFO_START - SFO phase of head swap started

[-partner-headswap-state <Headswap State>] - Partner Head Swap State (privilege: advanced)
Selects the nodes that have the specified partner node headswap state. Possible values are:
• HEADSWAP_NONE - head swap not in progress
• HEADSWAP_START - head swap started
• HEADSWAP_CFO_START - CFO phase of head swap started
• HEADSWAP_CFO_END - CFO phase of head swap completed
• HEADSWAP_SFO_START - SFO phase of head swap started

[-fast-timeout <integer>] - Fast Timeout (privilege: advanced)
Selects the nodes that have the specified fast-timeout configuration setting.

[-slow-timeout <integer>] - Slow Timeout (privilege: advanced)
Selects the nodes that have the specified slow-timeout setting.

[-mailbox-timeout <integer>] - Mailbox Timeout (privilege: advanced)
Selects the nodes that have the specified mailbox-timeout setting.
[-connect-timeout <integer>] - Connect Timeout (privilege: advanced)
Selects the nodes that have the specified connect-timeout setting.

[-operator-timeout <integer>] - Operator Timeout (privilege: advanced)
Selects the nodes that have the specified operator-timeout setting.

[-firmware-timeout <integer>] - Firmware Timeout (privilege: advanced)
Selects the nodes that have the specified firmware-timeout setting.

[-dumpcore-timeout <integer>] - Dumpcore Timeout (privilege: advanced)
Selects the nodes that have the specified dump-core timeout setting.

[-booting-timeout <integer>] - Booting Timeout (privilege: advanced)
Selects the nodes that have the specified booting-timeout setting.

[-transit-timer {true|false}] - Transit Timer Enabled (privilege: advanced)
Selects the nodes that have the specified transit-timer setting.

[-transit-timeout <integer>] - Transit Timeout (privilege: advanced)
Selects the nodes that have the specified transit timeout.

[-firmware-received <integer>] - Firmware Received (privilege: advanced)
Selects the nodes that have the specified firmware-reception time.

[-firmware-received-cycles <integer>] - Firmware Received in CPU Cycles (privilege: advanced)
Selects the nodes that have the specified firmware-reception time in CPU Cycles.

[-booting-received <integer>] - Booting Received (privilege: advanced)
Selects the nodes that have the specified booting-reception time.

[-transit-time <integer>] - Transit Event Time (privilege: advanced)
Selects the nodes whose last failover event occurred at the specified time.

[-pnormal <integer>] - Primary Normal IO Time (privilege: advanced)
Selects the nodes that have the specified normal primary-mailbox I/O time.

[-ptransition <integer>] - Primary Transition IO Time (privilege: advanced)
Selects the nodes that have the specified transitional primary-mailbox I/O time.

[-bnormal <integer>] - Backup Normal IO Time (privilege: advanced)
Selects the nodes that have the specified normal backup-mailbox I/O time.

[-btransition <integer>] - Backup Transition IO Time (privilege: advanced)
Selects the nodes that have the specified transitional backup-mailbox I/O time.

[-logs-unsynced <integer>] - Logs Unsynced Count (privilege: advanced)
Selects the nodes that have the specified count of unsynchronized logs.

[-auto-giveback {true|false}] - Auto Giveback Enabled
Selects the nodes that have the specified auto-giveback setting.

[-check-partner {true|false}] - Check Partner Enabled
Selects the nodes that have the specified partner-checking setting.

[-detection-time <integer>] - Takeover Detection Time (secs)
Selects the nodes that have the specified detection-time setting.

[-onfailure {true|false}] - Takeover on Failure Enabled (privilege: advanced)
Selects the nodes that have the specified takeover-on-failure setting.
[-onpanic {true|false}] - Takeover on Panic Enabled
   Selects the nodes that have the specified takeover-on-panic setting.

[-onshort-uptime {true|false}] - Takeover on Short Uptime Enabled (privilege: advanced)
   Selects the storage-failover configurations that match this parameter value.

[-short-uptime <integer>] - Short Uptime (secs) (privilege: advanced)
   Selects the nodes that have the specified short-uptime value.

[-attempts <integer>] - Number of Giveback Attempts (privilege: advanced)
   Selects the nodes that have the specified number of giveback attempts.

[-attempts-time <integer>] - Giveback Attempts Period (minutes) (privilege: advanced)
   Selects the nodes that have the specified time setting for giveback attempts.

[-propagate {true|false}] - Propagate Status via Mailbox (privilege: advanced)
   Selects the nodes that have the specified propagate-status-via-mailbox setting.

[-read-interval <integer>] - Node Status Read Interval (secs) (privilege: advanced)
   Selects the nodes that have the specified read interval.

[-write-interval <integer>] - Node Status Write Interval (secs) (privilege: advanced)
   Selects the nodes that have the specified write interval.

[-onreboot {true|false}] - Takeover on Reboot Enabled
   Selects the nodes that have the specified takeover-on-reboot setting.

[-delay-seconds <integer>] - Delay Before Auto Giveback (secs)
   Selects the nodes that have the specified delay (in seconds) for the auto giveback.

[-hwassist {true|false}] - Hardware Assist Enabled
   Selects the nodes that have the specified hwassist setting.

[-hwassist-partner-ip <IP Address>] - Partner's Hwassist IP
   Selects the nodes that have the specified hwassist-partner-ip setting.

[-hwassist-partner-port <integer>] - Partner's Hwassist Port
   Selects the nodes that have the specified hwassist-partner-port setting.

[-hwassist-health-check-interval <integer>] - Hwassist Health Check Interval (secs)
   Selects the nodes that have the specified hwassist health check interval, in seconds.

[-hwassist-retry-count <integer>] - Hwassist Retry Count
   Selects the nodes that have the specified hwassist retry count, in seconds.

[-hwassist-status <text>] - Hwassist Status
   Selects the nodes that have the specified hwassist-status setting.

[-time-until-autogiveback <integer>] - Time Until Auto Giveback (secs)
   Selects the nodes that have the specified time(in seconds) until auto giveback.

[-local-mailbox-disks <text>] - Local Mailbox Disks
   Selects the nodes that have the specified mailbox disks on the local node.

[-partner-mailbox-disks <text>] - Partner Mailbox Disks
   Selects the nodes that have the specified mailbox disks on the partner node.

[-local-firmware-state <text>] - Local Firmware State (privilege: advanced)
   Selects the nodes that have the specified firmware state on the local node.
[-local-firmware-progress <integer>] - Local Firmware Progress Counter (privilege: advanced)
Selects the nodes that have the specified firmware progress counter for the local node.

[-partner-firmware-state <text>] - Partner Firmware State (privilege: advanced)
Selects the nodes that have the specified firmware state of the partner node.

[-partner-firmware-progress <integer>] - Partner Firmware Progress Counter (privilege: advanced)
Selects the nodes that have the specified firmware progress counter for the partner node.

[-local-missing-disks <text>] - Missing Disks on Local Node
Selects the nodes that have the specified missing disks on the local node.

[-partner-missing-disks <text>] - Missing Disks on Partner Node
Selects the nodes that have the specified missing disks on the partner node.

[-reboot-timeout <integer>] - Reboot Timeout (privilege: advanced)
Selects the nodes that have the specified reboot timeout.

[-time-since-takeover <text>] - Time Since Takeover
Selects the nodes that have been in takeover mode for the specified amount of time.

[-auto-giveback-after-panic {true|false}] - Auto Giveback After Takeover On Panic
Selects the nodes that have the specified auto-giveback-after-panic setting. If true then an automatic giveback operation is invoked when the failover node of an HA pair is repaired and rebooted. The takeover node of the HA pair detects this and initiates a giveback operation automatically.

[-is-giveback-requested {true|false}] - Giveback Requested (privilege: advanced)
Selects the nodes that have the specified is-giveback-requested setting. If true, a deferred giveback request has been made by the local node.

[-auto-giveback-last-veto-check <integer>] - Auto Giveback Last Veto Check (privilege: advanced)
Selects the nodes that have the specified auto-giveback-last-veto-check time. This setting indicates the time, in milliseconds, when the local node made the most recent giveback veto check.

[-is-auto-giveback-attempts-exceeded {true|false}] - Auto Giveback Attempts Exceeded (privilege: advanced)
Selects the nodes that have the specified is-auto-giveback-attempts-exceeded setting. If true, the local node has exceeded the maximum number of allowed auto giveback attempts.

[-was-auto-giveback-done {true|false}] - Was Auto Giveback Done (privilege: advanced)
Selects the nodes that have the specified was-auto-giveback-done setting. If true, the last giveback was automatic (as opposed to a manual giveback).

[-is-cifs-auto-giveback-stopping {true|false}] - Is CIFS Auto Giveback Stopping (privilege: advanced)
Selects the nodes that have the specified is-cifs-auto-giveback-stopping setting. If true, the local node has initiated CIFS termination as part of an automatic giveback.

[-bypass-takeover-optimization {true|false}] - Bypass Takeover Optimization Enabled
Selects the nodes that have the specified bypass-takeover-optimization setting. If the value is set to true then optimized operator-initiated planned takeover is bypassed. Operator initiated planned takeover is optimized when SFO aggregates are relocated serially to the partner prior to takeover. This reduces client outage. If the value is set to false then optimized operator-initiated planned takeover is enabled on this node.

[-aggregate-migration-timeout <integer>] - Aggregate Migration Timeout (secs) (privilege: advanced)
Selects the nodes that have the specified aggregate migration timeout.

[-auto-giveback-override-vetoes {true|false}] - Auto-giveback Override Vetoes Enabled
Selects the nodes that have the specified auto-giveback-override-vetoes setting.
[-is-mirror-enabled \{true|false\}] - Is NVRAM Mirroring Enabled (privilege: advanced)
Selects the nodes that have the specified is-mirror-enabled setting. If true, then NVRAM mirroring is enabled.

[-is-mirror-consistency-required \{true|false\}] - Is Mirror Consistency Required (privilege: advanced)
Selects the nodes that have the specified is-mirror-consistency-required setting. If true, then NVRAM mirror consistency is required.

[-is-memory-insufficient \{true|false\}] - Is Memory Insufficient To Takeover (privilege: advanced)
Selects the nodes that have the specified is-memory-insufficient setting. If true, the local node does not have enough memory to perform a takeover.

[-memio-state <memio status>] - Current State of Memio Link (privilege: advanced)
Selects the nodes that have the specified memio layer link current state. Possible values are:

• UNINIT - Uninitialized
• CLOSED - Closed
• HB_LISTEN - Listening for connect
• SYN_SENT - Sent generation information
• ESTABLISHED - Connection established

[-is-degraded \{true|false\}] - Are Partner Mailbox Disks Not Known (privilege: advanced)
Selects the nodes that have the specified is-degraded setting. If true, takeovers are deferred because partner mailbox disks are not known.

[-reserve-policy <reserve policy>] - FM Reservation Policy (privilege: advanced)
Selects the nodes that have the specified disk reservation policy. Possible values are:

• RESERVE_NO_DISKS - no disk reservations made during takeover, nor are disk reservations released during giveback
• RESERVE_LOCK_DISKS_ONLY - only mailbox disks are released during takeover and released during giveback
• RESERVE_ONLY_AT_TAKEOVER - reservations are issued only at takeover time. All disks are reserved. All reservations are released at giveback
• RESERVE_ALWAYS_AFTER_TAKEOVER - reservations are issued at at takeover. When disks are subsequently added, they are also reserved. All disks are released at giveback

[-reset-disks \{true|false\}] - Issue Disk Resets during Failover (privilege: advanced)
Selects the nodes that have the specified reset-disks setting. If true, disks are reset during takeover/giveback.

[-total-system-uptime <integer>] - Total System Uptime (privilege: advanced)
Selects the nodes that have the specified total system uptime, in milliseconds.

[-current-time <integer>] - Current System Time (privilege: advanced)
Selects the nodes that have the specified current time on the node.

[-fm-takeover-state <FM Takeover/Giveback Transition>] - FM Takeover State (privilege: advanced)
Selects the nodes that have the specified takeover state. Possible values are:

• FT_NONE - Not in takeover
• FT_TAKEOVER_STARTED - Local node has initiated takeover
• FT_TAKEOVER_COMMITTED - Takeover has been committed
• **FT_TAKEOVER_DONE_OK** - Local node successfully completed takeover
• **FT_TAKEOVER_DONE_FAILED** - Takeover failed

```-fm-giveback-state <FM Takeover/Giveback Transition> [-]```
FM Giveback State (privilege: advanced)
Selects the nodes that have the specified giveback state. Possible values are:

• **FT_NONE** - Not in giveback
• **FT_GIVEBACK_READY** - Partner node is ready for giveback
• **FT_GIVEBACK_STARTED** - Local node has initiated giveback
• **FT_GIVEBACK_COMMITTED** - Giveback has been committed
• **FT_GIVEBACK_DONE_OK** - Giveback completed successfully

```-auto-giveback-cifs-terminate-minutes <integer> [-]```
Auto Giveback Delay Before Terminating CIFS (minutes)
If this parameter is specified, the command displays information only about the storage-failover configuration or configurations that have the specified auto giveback delay before terminating CIFS.

```-takeover-reason <FM Takeover Reason> [-]```
Reason why takeover triggered (privilege: advanced)
Selects the nodes that have the specified takeover reason. Possible values are:

• **TAKEOVER_NONE** - Not in takeover
• **TAKEOVER_IMMEDIATE** - Operator initiated forced takeover
• **TAKEOVER_NDU** - Takeover initiated as part of NDU
• **TAKEOVER_FORCED** - Operator initiated forced takeover, possible data loss
• **TAKEOVER_EARLY** - Takeover occurred during the boot process
• **TAKEOVER_OPERATOR_EXP** - Takeover occurred after the operator timeout expired
• **TAKEOVER_POST_FAILED** - Takeover occurred on POST failure
• **TAKEOVER_PANIC** - Takeover on panic
• **TAKEOVER_SHORTUPTIME** - Takeover after rapid toggling between up and down states
• **TAKEOVER_SPARECORE_EXP** - Takeover on panic timeout expiration
• **TAKEOVER_REBOOT_EXP** - Takeover on reboot timer expiration
• **TAKEOVER_BOOTING_EXP** - Takeover on booting timer expiration
• **TAKEOVER_FIRMWARE_EXP** - Takeover on firmware timer expiration
• **TAKEOVER_NFO_SHUTDOWN** - Takeover on negotiated failover shutdown
• **TAKEOVER_NFO_TIMER** - Takeover on negotiated failover timer expiration
• **TAKEOVER_MDP** - Takeover on multi-disk panic
• **TAKEOVER_REBOOT** - Takeover on reboot
• **TAKEOVER_HALT** - Takeover on halt
• **TAKEOVER_CLAM** - CLAM-triggered takeover
• **TAKEOVER_HWASSIST** - Hardware-assisted takeover
• TAKEOVER_NORMAL - Operator initiated takeover

[-ha-type \{none|shared_storage|non_shared_storage\}] - HA Type

If this parameter is specified, the command selects the nodes that have the specified HA-type setting. If the value is set to shared_storage, then the node is in a storage-failover configuration using the shared storage. If it is set to non_shared_storage, then the node is in a storage-failover configuration using the unshared storage. If it is set to none, then the node is not part of a storage-failover configuration.

Examples
The following example displays information about all storage-failover configurations:

```
cluster1::> storage failover show
+----------+----------+--------------+------------------+
<table>
<thead>
<tr>
<th>Node</th>
<th>Partner</th>
<th>Possible</th>
<th>State</th>
</tr>
</thead>
<tbody>
<tr>
<td>node0</td>
<td>node1</td>
<td>true</td>
<td>Connected to node1</td>
</tr>
<tr>
<td>node2</td>
<td>node3</td>
<td>true</td>
<td>Connected to node3</td>
</tr>
<tr>
<td>node1</td>
<td>node0</td>
<td>true</td>
<td>Connected to node0</td>
</tr>
<tr>
<td>node3</td>
<td>node2</td>
<td>true</td>
<td>Connected to node2</td>
</tr>
</tbody>
</table>
+----------+----------+--------------+------------------+
4 entries were displayed.
```

storage failover show-giveback

Display giveback status

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The storage failover show-giveback command displays information about the giveback status of high-availability (HA) partner aggregates. The command displays the following information when no parameters are specified:

• Node name
• Partner aggregate name
• Giveback Status

You can specify additional parameters to display only the information that matches those parameters. For example, to display information only about a particular aggregate, run the command with the -aggregate aggregate_name parameter.

Parameters

[-fields <fieldname>, ...]  
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

[-instance ]  
If you specify the -instance parameter, the command displays detailed information about all fields.

[-node \{<nodename>|local\}] - Node  
If this parameter is used, the command displays information about the giveback status of the aggregates belonging to the HA partner of the specified node.

[-aggregate <text>] - Aggregate  
If this parameter is used, the command displays information about the giveback status of the specified aggregate.
[-giveback-status <text>, ...] - Aggregates Giveback State

If this parameter is used, the command displays information about the aggregates with the specified giveback status.

[-destination <text>] - Destination for Giveback

If this parameter is used, the command displays information about the giveback status of the aggregates whose destination after the giveback is the specified node.

### Examples

The following example displays information about giveback status on all nodes:

```plaintext
node::> storage failover show-giveback
Partner                 Aggregate         Giveback Status
-------------- ----------------- -------------------------------------------
node0 -                 No aggregates to give back
node1 -                 No aggregates to give back
node2 -                 No aggregates to give back
node3 -                 No aggregates to give back
4 entries were displayed.
```

### storage failover show-takeover

Display takeover status

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**

The `storage failover show-takeover` command displays information about the takeover status of nodes in a cluster. The command also displays the takeover status of aggregates being taken over. During each phase of takeover, the takeover node and the node being taken over display their takeover status and the status of the aggregates being taken over. The command displays the following information when no parameters are specified:

- **Node name**
- **Node takeover status** - This contains a descriptive information about the phase of takeover.
- **Aggregate**
- **Aggregate takeover status** - This contains the following information:
  - Takeover status of the aggregate, such as "Done", "Failed", "In progress" and "Not attempted yet".
  - Reason for an aggregate takeover failure.
  - Corrective action, in case of an aggregate takeover failure.

You can specify additional parameters to display only the information that matches those parameters. For example, to display information only about a particular node, run the command with the `-node node_name` parameter.

**Parameters**

```plaintext
[-fields <fieldname>, ...]
```

If this parameter is specified, the command displays the specified fields for all nodes, in column style output.
If this parameter is specified, the command displays the same detailed information as for the \texttt{-node} parameter, but for all nodes.

\textbf{[-node \{<nodename> | local\}] - Node Name}
If this parameter is specified, the command displays information about the takeover status of the specified node, and the takeover status of the aggregates being taken over.

\textbf{[-node-takeover-status <text>] - Node's Takeover Status}
If this parameter is specified, the command displays information about the takeover status of the nodes with the specified node-takeover-status. The command also displays the takeover status of the aggregates belonging to the node being taken over.

\textbf{[-aggregate <text>] - Aggregate Being Taken Over}
If this parameter is specified, the command displays information about the takeover status of the specified aggregate, and the takeover status of the nodes containing the specified aggregate.

\textbf{[-aggregate-takeover-status <text>] - Aggregate's Takeover Status}
If this parameter is specified, the command displays information about the takeover status of the aggregates with the specified aggregate takeover status, and the takeover status of the nodes containing those aggregates.

\section*{Examples}
The following example shows the takeover status of two nodes, nodeA and nodeB, in an High Availability (HA) pair, when both are in normal mode; neither node has taken over its HA partner. In this case, there is no takeover status for the aggregates.

\input{example1}

\begin{verbatim}
cluster1::> storage failover show-takeover
Node       Node Status           Aggregate      Takeover Status
---------- --------------------- -------------- -------------------------------
nodeA      Takeover not attempted.  -              -
nodeB      Takeover not attempted.  -              -
\end{verbatim}

The following example shows the takeover status of two nodes, nodeA and nodeB, in an HA pair, when nodeA is in the SFO phase of an optimized takeover of nodeB. In this case, nodeA does not have information about the takeover status of nodeB's aggregates.

\input{example2}

\begin{verbatim}
cluster1::> storage failover show-takeover
Node       Node Status           Aggregate      Takeover Status
---------- --------------------- -------------- -------------------------------
nodeA      Optimized takeover of partner in progress. Partner, ("nodeB"), is relocating its SFO aggregates. Run the command "storage failover show-takeover -node nodeB" to display the relocation status of the partner.
nodeB      Being taken over.        -              -
aggr1      In progress, Module: backup.
aggr2      Not attempted yet
CFO aggregates Not attempted yet.
\end{verbatim}
The following example shows the takeover status of two nodes, nodeA and nodeB, in an HA pair, when nodeA has completed the SFO phase of an optimized takeover of nodeB (but has not completed the CFO phase of the optimized takeover). In this case, nodeA has information about the takeover status of nodeB’s aggregates.

```
cluster1::> storage failover show-takeover
Node       Node Status           Aggregate      Takeover Status
---------- --------------------- -------------- -------------------------------
nodeA      Partner has relocated its aggregates. Takeover in progress.  
           aggr1          Done
           aggr2          Done
           CFO aggregates In progress.
nodeB      Relocated aggregates to partner. Waiting for partner to takeover. 
           aggr1          Done
           aggr2          Done
           CFO aggregates Not attempted yet.
```

The following example shows the takeover status of two nodes, nodeA and nodeB, in an HA pair, when nodeA has completed the SFO and CFO phases of an optimized takeover of nodeB. In this case, nodeA has information about the takeover status of nodeB’s aggregates. Since nodeB is not operational, an Remote Procedure Call(RPC) error is indicated in the command output.

```
cluster1::> storage failover show-takeover
Node       Node Status           Aggregate      Takeover Status
---------- --------------------- -------------- -------------------------------
nodeA      Partner has relocated its aggregates. In takeover. 
           aggr1          Done
           aggr2          Done
           CFO aggregates Done.
Warning: Unable to list entries on node nodeB. RPC: Port mapper failure - RPC: Timed out
```

The following example shows the takeover status of two nodes, nodeA and nodeB, in an HA pair, when nodeA has aborted the SFO phase of an optimized takeover of nodeB. In this case, nodeA does not have information about the takeover status of nodeB’s aggregates.

```
cluster1::> storage failover show-takeover
Node       Node Status           Aggregate      Takeover Status
---------- --------------------- -------------- -------------------------------
nodeA      Optimized takeover of partner aborted. 
           Run the command
           "storage failover show-takeover -node nodeB" to display the relocation status of the partner. 
           -              -
nodeB      Optimized takeover by partner aborted. 
           aggr1          Failed: Destination node did not online the aggregate on time. To takeover the remaining aggregates, run the "storage failover takeover -ofnode nodeB -bypass-optimization true" command. To giveback the relocated aggregates, run the "storage failover giveback 
```
storage failover takeover

Take over the storage of a node's partner

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The storage failover takeover command initiates a takeover of the partner node's storage.

Parameters

- **-ofnode** `<nodename> | local` - Node to Takeover
  This specifies the node that is taken over. It is shut down and its partner takes over its storage.

- **-bynode** `<nodename> | local` - Node Initiating Takeover
  This specifies the node that is to take over its partner's storage.

- **-option** `<takeover option>` - Takeover Option
  This optionally specifies the style of takeover operation. Possible values include the following:

  - normal - Specifies a normal takeover operation; that is, the partner is given the time to close its storage resources gracefully before the takeover operation proceeds. This is the default value.

  - immediate - Specifies an immediate takeover. In an immediate takeover, the takeover operation is initiated before the partner is given the time to close its storage resources gracefully. The use of this option results in an immediate takeover which does not do a clean shutdown. In case of NDU this can result in a NDU failure.

    **Attention:** If this option is specified, negotiated takeover optimization is bypassed even if the `-bypass-optimization` option is set to false.

    **Attention:** If this option is specified, migration of data LIFs from the partner will be delayed even if the `-skip-lif-migration-before-takeover` option is not specified. If possible, migrate the data LIFs to another node prior to specifying this option.

  - allow-version-mismatch - If this value is specified, the takeover operation is initiated even if the partner is running a version of software that is incompatible with the version running on the node. In this case, the partner is given the time to close its storage resources gracefully before the takeover operation proceeds. However, the takeover operation will not be allowed if the partner has higher WAFL or RAID label versions. Use this value as part of a nondisruptive upgrade or downgrade procedure.

  - force - If this value is specified, the takeover operation is initiated even if the node detects an error that normally prevents a takeover operation from occurring. This value is available only at the advanced privilege level and higher.

    **Attention:** If this option is specified, negotiated takeover optimization is bypassed even if the `-bypass-optimization` option is set to false.

    **Caution:** The use of this option can potentially result in data loss. If the HA interconnect is detached or inactive, or the contents of the failover partner's NVRAM cards are unsynchronized, takeover is normally disabled. Using the `-force` option enables a node to take over its partner's storage despite the unsynchronized NVRAM, which can contain client data that can be lost upon storage takeover.
[-bypass-optimization {true|false}] - Bypass Takeover Optimization

If this is an operator-initiated planned takeover, this parameter specifies whether the takeover optimization is bypassed. This parameter defaults to false.

Attention: This parameter is ignored and negotiated takeover optimization automatically bypassed if the -immediate option, the -force option, or the -allow-disk-inventory-mismatch parameter is specified as part of the same storage failover takeover command.

[-allow-disk-inventory-mismatch {true|false}] - Disk inventory

If this parameter is specified, the takeover operation is initiated even if the local node cannot see the partner’s filesystem disks.

Attention: If this parameter is specified, negotiated takeover optimization is bypassed even if the -bypass-optimization parameter is set to false.

Caution: The use of this parameter can potentially result in client outage.

[-skip-lif-migration-before-takeover {true}] - Skip Migrating LIFs Away from Node Prior to Takeover

This parameter specifies that LIF migration prior to takeover is skipped. However if LIFs on this node are configured for failover, those LIFs may still failover after the takeover has occurred. Without this parameter, the command attempts to synchronously migrate data and cluster management LIFs away from the node prior to its takeover. If the migration fails or times out, the takeover is aborted.

[-ignore-quorum-warnings {true}] - Skip Quorum Check Before Takeover

If this parameter is specified, quorum checks will be skipped prior to the takeover. The operation will continue even if there is a possible data outage due to a quorum issue.

Examples

The following example causes a node named node0 to initiate a negotiated optimized takeover of its partner's storage:

```
cluster1::> storage failover takeover -bynode node0
```

The following example causes a node named node0 to initiate an immediate takeover of its partner's storage:

```
cluster1::> storage failover takeover -bynode node0 -option immediate
```

storage failover hwassist commands

Hardware assist functionality related commands

In a high-availability configuration, a storage controller monitors its partner's health using heartbeats. On storage controller failures, the takeover starts after a storage controller misses several heartbeats - which by default can take up to 15 seconds after the failure occurs. When the hardware-assisted takeover (hwassist) feature is enabled, the service processor of the storage controller (SP, RLM or BMC) is able to detect various failures, such as: Power Loss, Power Cycle, and POST Error. In these cases, the failover detection time is less than a second, allowing the takeover to start much sooner. Use the "storage failover modify" command to configure the hwassist feature.

storage failover hwassist show

Display hwassist status

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The storage failover hwassist show command displays information about hardware assisted takeover configurations. By default, the command displays the following information:
- Node name.
- Partner node name.
- Whether hardware assisted takeover is enabled.
- IP address on which the local node receives hardware assist alerts.
- Port on which local node receives hardware assist alerts.
- Hardware assist monitor status.
- If the monitor is inactive, the reason it is inactive.
- If the monitor is inactive, the corrective action to make it active.

**Parameters**

```
[-fields <fieldname>, ...]
```

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

```
[-instance]
```

If you specify the `-instance` parameter, the command displays detailed information about all fields.

```
[-node <nodename>|local] - Node
```

Selects the hwassist configurations that match this parameter value.

```
[-partner-name <nodename>|local] - Name of the Partner Node
```

Selects the hwassist configurations that match this parameter value.

```
[-enabled {true|false}] - Local Hardware Assist Enabled
```

Selects the hwassist configurations that match this parameter value.

```
[-local-status <text>] - Local Node's Hwassist Status
```

Selects the hwassist configurations that match this parameter value (active or inactive).

```
[-local-ip <text>] - IP Address on Which Local Node is Listening
```

Selects the hwassist configurations that match this parameter value.

```
[-local-port <integer>] - Port on Which Local Node is Listening
```

Selects the hwassist configurations that match this parameter value.

```
[-local-inactive <text>] - Local Node's Hwassist Inactive Status Reason
```

Selects the hwassist configurations that match this parameter value.

```
[-local-action <text>] - Corrective Action on Local Node
```

Selects the hwassist configurations that match this parameter value.

**Examples**

The following example displays the hardware assist information for the local node and its partner:

```
cluster1:~> storage failover hwassist show
Node
-------
ha1       Partner : ha2
          Hwassist Enabled : true
          Hwassist IP : 10.225.248.19
          Hwassist Port : 4444
          Monitor Status : active
          Inactive Reason : -
          Corrective Action : -
ha2
```
storage failover hwassist test

Test the hwassist functionality

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The `storage failover hwassist test` command tests the Hardware Assist h/w connectivity between the two nodes in a HA pair. The test result can be one of the following.

- Hardware Assist is not initialized.
- HW assist is not supported.
- Partner is throttling alerts.
- Resource is busy.
- Hardware Assist h/w returned an error.
- No response from partner:Timed out.
- Unexpected abort.
- Partner has taken over.
- Interconnect is down between nodes.
- Partner is not booted up yet.

Parameters

```
-node <nodename> | local - Node
```
This specifies the node from which a test alert is initiated.

Examples

The following command issues a test alert from the node cluster1-01:

```
cluster1:/> storage failover hwassist test -node cluster1-01
Info: Operation successful.
```

storage failover hwassist stats commands

Hwassist statistics related commands

In a Hardware Assisted environment a node receives various alerts with from the partner node, periodically. Data ONTAP keeps track of all these alerts and maintains statistics about them. The user can see these statistics or clear them.
storage failover hwassist stats clear

Clear the hwassist statistics

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The storage failover hwassist stats clear command clears the statistics information maintained by Hardware Assist functionality.

Parameters
-node {<nodename>|local} - Node
This specifies the node on which the statistics are to be cleared.

Examples
The following example clears the hwassist statistics on the node cluster1-01:

```
cluster1::> storage failover hwassist stats clear -node cluster1-01
```

storage failover hwassist stats show

Display hwassist statistics

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The storage failover hwassist stats show command displays statistics about the hardware assist alerts processed by a node. The command displays the following information for each alert:

- Locally enabled.
- Partner Inactive Reason.
- Alert type.
- Event that triggered the alert.
- The number of times the alert has been received.
- Whether takeover was possible on receiving the alert.
- The last time at which the alert was received.

Parameters
{}

If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

- [ ]
If you specify the -instance parameter, the command displays detailed information about all fields.

- -node {<nodename>|local} - Node
Selects the hwassist statistics for the specified node.
Examples
The following example displays the hwassist statistics for the node ha1:

```
cluster1::> storage failover hwassist stats show -node ha1
```

Node: ha1
Local Enabled: true
Partner Inactive Reason: -

storage failover interconnect commands
Display information about the storage failover interconnect

storage failover interconnect show-link
(DEPRECATED)-Display information about the storage failover interconnect link

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
Note: This command has been deprecated and may be removed from a future version of Data ONTAP. Use the `system ha interconnect status` command instead.

The `storage failover interconnect show-link` command displays information about the storage failover interconnect links in the cluster.
Parameters

\{ [-fields <fieldname>, ...] \}

If you specify the \{-fields <fieldname>, ...\} parameter, the command output also includes the specified field or fields. You can use \{-fields ?\} to display the fields to specify.

\{ [-instance] \}

If you specify the \{-instance\} parameter, the command displays detailed information about all fields.

\{-node \{<nodename> | local\}\} - Node

Use this parameter to display information only about the interconnect links on the specified node.

\{-link-number <integer>\} - Link Number

Use this parameter to display information only about nodes that have the number of interconnect links you specify.

\{-link-state <text>\} - Link State

Use this parameter to display information only about the interconnect links that are in the state you specify. Valid values are \textit{up} and \textit{down}.

Examples

The following example displays information about all storage-failover interconnect links in the cluster:

```
cluster1::*> storage failover interconnect show-link
Node          Port Number      Link State
------------------------------------------------------------------------------
node1          0                down
               1                up
node2          0                down
               1                up
4 entries were displayed.
```

\textit{system ha interconnect status} on page 1006

\textbf{storage failover interconnect status}

(DEPRECATED) - Display the state of the storage failover interconnect and active logical links

\textbf{Availability:} This command is available to cluster administrators at the \textit{advanced} privilege level.

\textbf{Description}

\textbf{Note:} This command has been deprecated and may be removed from a future version of Data ONTAP. Use the \textit{system ha interconnect status} command instead.

The \textit{storage failover interconnect status} command displays status information about the storage failover interconnects in the cluster.

\textbf{Parameters}

\{ [-fields <fieldname>, ...] \}

If you specify the \{-fields <fieldname>, ...\} parameter, the command output also includes the specified field or fields. You can use \{-fields ?\} to display the fields to specify.

\{ [-instance] \}

If you specify the \{-instance\} parameter, the command displays detailed information about all fields.
[-node {<nodename> | local}] - Node
Use this parameter to display information only about the interconnect status of the nodes you specify.

[-state <text>] - Storage Failover Connection State
Use this parameter to display information only about the interconnects that are in the state you specify.
Possible values are connected and disconnected.

[-active-link <integer>] - Active Logical Link
Use this parameter to display information about the interconnects for the nodes on which the specified logical link is active.

Examples
The following example displays storage-failover interconnect status for all nodes in the cluster:

```
cluster1:*> storage failover interconnect status
Node           Connection State        Active Logical Link
------------------------------------------------------------------------------
node1            Disconnected            1
node2            Disconnected            1
2 entries were displayed.
```

Display statistics for the storage failover interconnect

**storage failover interconnect statistics error commands**
Display error statistics for the storage failover interconnect

**storage failover interconnect statistics error show**
(DEPRECATED)-Display error statistics for the storage failover interconnect

**Availability:** This command is available to cluster administrators at the advanced privilege level.

**Description**

**Note:** This command has been deprecated and may be removed from a future version of Data ONTAP. Use the following commands instead for all interconnect related error statistics. `statistics show -object ic_error_stats` to display basic error statistics. `statistics show -object ic_vi_errors` to display error statistics that are valid on FAS2000 series. `statistics show -object ic_hw_sinai_nic_stats` to display interconnect hardware specific error statistics on FAS2000 series. `statistics show -object ic_rdma_errors` to display error statistics that are valid on FAS3200 series, FAS6200 series and FAS8000 series. `statistics show -object ic_mvia_stats` to display error statistics that are valid on virtual instance of the Data ONTAP. `statistics show -object ic_hw_error_stats` to display interconnect hardware specific error statistics on FAS6200 series and FAS8000 series. For all the above commands, use `statistics start -object objectname` and `statistics stop -object objectname` commands to start and stop collection of the statistics for the desired object.

The `storage failover interconnect statistics error show` command displays node-specific error statistics about the storage-failover interconnect.
Parameters
{[-fields <fieldname>, ...]}
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

{|[-instance]]}
If you specify the -instance parameter, the command displays detailed information about all fields.

[-node {<nodename>|local}] - Node
Selects error statistics for the specified node.

[-type {rv|nvram5-sw|nvram5-hw-error|nvram5-hw-perf|nvram5-port-1|nvram5-port-2}] - Error Statistics Type
Selects the error statistics of the specified type.

[-counter <text>] - Error Counter Name
Selects the error statistics for the specified error counter.

[-value <integer>] - Error Counter Value
Selects the error statistics that match the specified counter value.

Examples
The following example displays the counter named RV connection attempts for statistic type RV on the node named node0:

cluster1::*> storage failover interconnect statistics error show -node node0 -type RV -counter "RV connection attempts"
Node Name : node0
Error Statistics Type : RV
Error Counter Name : RV connection attempts
Counter Value : 2

storage failover interconnect statistics performance commands
Display performance statistics for the storage failover interconnect

storage failover interconnect statistics performance basic
(DEPRECATED)-Display basic performance statistics for the storage failover interconnect
Availability: This command is available to cluster administrators at the advanced privilege level.

Description
Note: This command has been deprecated and may be removed from a future version of Data ONTAP. Use the system ha interconnect statistics performance show command instead.

The storage failover interconnect statistics performance basic command displays basic performance statistics for the storage-failover interconnect.
Parameters

{[-fields <fieldname>, ...]

If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

[-instance ]

If you specify the -instance parameter, the command displays detailed information about all fields.

[-node <nodename> | local] - Node

Specify this parameter to display only statistics for the node you specify.

[-counter <text>] - Error Counter Name

Specify this parameter to display only the statistic counter you specify.

[-value <integer>] - Error Counter Value

Specify this parameter to display only statistics that have the value you specify.

Examples

The following example displays basic performance statistics for a node named node0:

```
cluster1::*> storage failover interconnect statistics performance basic -node node0

storage failover interconnect statistics performance vi-if

(DEPRECATED)-Display vi-if performance statistics for the storage failover interconnect

Availability: This command is available to cluster administrators at the advanced privilege level.
Description

**Note:** This command has been deprecated and may be removed from a future version of Data ONTAP. Use the following commands instead. `statistics start -object ic_viif_stats` to start collection of the statistics. `statistics show -object ic_viif_stats` to display the collected statistics. `statistics stop -object ic_viif_stats` to stop collection of the statistics.

The `storage failover interconnect statistics performance vi-if` command displays performance statistics on a per-interface basis for the storage-failover interconnect.

**Parameters**

```
[-fields <fieldname>, ...]  
If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.
```

```
[-instance ]  
If you specify the `-instance` parameter, the command displays detailed information about all fields.
```

```
[-node {<nodename>|local}] - Node  
Specify this parameter to display only statistics for the node you specify.
```

```
[-interface <integer>] - VI_IF Interface  
Specify this parameter to display only statistics for the messaging interface you specify. Possible values are 0 and 1.
```

```
[-counter <text>] - Error Counter Name  
Specify this parameter to display only the statistic counter you specify.
```

```
[-value <integer>] - Error Counter Value  
Specify this parameter to display only statistics that have the counter value you specify.
```

**Examples**

The following example displays per-interface performance statistics for the storage-failover interconnect on a node named `node0a`:

```
cluster1:/> storage failover interconnect statistics performance vi-if node0a
Node    Interface   Counter Name                         Counter Value
node0a  0           Send credit                         35
node0a  0           Send Queue length                   0
node0a  0           Send Queue full                     0
node0a  0           Sent Queue length                   0
node0a  0           Sent data                           86868
node0a  0           Receive Queue length                36
node0a  0           Received data                       86868
node0a  0           Explicit credit updates received    35
node0a  0           Explicit credit updates sent        35
node0a  0           Piggyback credit updates received    1143
node0a  0           Piggyback credit updates sent        1142
node0a  0           Sent mbufs                          1143
node0a  0           Recv mbufs freed by vi_if            1
node0a  0           Recv mbufs freed by client           1143
node0a  1           Send credit                         33
node0a  1           Send Queue length                   0
node0a  1           Send Queue full                     0
node0a  1           Sent Queue length                   1
node0a  1           Sent data                           12230704
node0a  1           Receive Queue length                36
node0a  1           Received data                       12230784
node0a  1           Explicit credit updates received    35
node0a  1           Explicit credit updates sent        35
node0a  1           Piggyback credit updates received    509611

storage failover internal-options commands

Display the internal options for storage failover

This contains commands related to displaying and modifying internal options for storage failover of a node.

storage failover internal-options show

Display the internal options for storage failover

Availability: This command is available to cluster administrators at the advanced privilege level.

Description

The storage failover internal-options show command displays the following information about the storage failover configuration:

- Node name
- Whether automatic giveback is enabled
- Whether partner checking is enabled
- Takeover detection time, in seconds
- Whether takeover on failover is enabled
- Whether takeover on panic is enabled
- Whether takeover on reboot is enabled
- Whether hardware-assisted takeover is enabled
- IP address on which the partner node listens to the hardware-assisted takeover alerts
- Port on which the partner node listens to the hardware-assisted takeover alerts
- Whether takeover on short uptime is enabled (detailed view only)
- Short uptime interval, in seconds (detailed view only)
- Number of giveback attempts (detailed view only)
- Giveback attempt interval, in minutes (detailed view only)
- Whether status is propagated through SFO mailboxes (detailed view only)
- Status read interval, in seconds (detailed view only)
- Status write interval, in seconds (detailed view only)
- Hardware-assisted takeover retry count (detailed view only)
- Hardware-assisted takeover heartbeat period (detailed view only)
- Whether operator-initiated planned takeover is optimized

**Parameters**

`[-fields <fieldname>, ...]`

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

`[-more]`

This parameter displays the following additional information:

- Node name
- Whether takeover on short uptime is enabled
- Short uptime interval, in seconds
- Number of giveback attempts
- Giveback attempt interval, in minutes
- Whether status is propagated through SFO mailboxes
- Status read interval, in seconds
- Status write interval, in seconds
- Hardware-assisted takeover retry count
- Hardware-assisted takeover heartbeat period

`[-instance]`

If you specify the `-instance` parameter, the command displays detailed information about all fields.

`[-node <nodename>|local] - Node`

Selects configuration information for the specified node.

`[-auto-giveback {true|false}] - Auto Giveback Enabled`

Selects configuration information for nodes that have the specified automatic giveback setting.

`[-check-partner {true|false}] - Check Partner Enabled`

Selects configuration information for nodes that have the specified partner-checking setting.

`[-detection-time <integer>] - Takeover Detection Time (secs)`

Selects configuration information for nodes that have the specified takeover detection time setting.

`[-onfailure {true|false}] - Takeover on Failure Enabled`

Selects configuration information for nodes that have the specified takeover-on-failure setting.

`[-onpanic {true|false}] - Takeover on Panic Enabled`

Selects configuration information for nodes that have the specified takeover-on-panic setting.

`[-onshort-uptime {true|false}] - Takeover on Short Uptime Enabled`

Selects configuration information for nodes that have the specified takeover-on-short-uptime setting.

`[-short-uptime <integer>] - Short Uptime (secs)`

Selects configuration information for nodes that have the specified takeover-on-short-uptime time setting.

`[-attempts <integer>] - Number of Giveback Attempts`

Selects configuration information for nodes that have the specified number of giveback attempts setting.
[-attempts-time <integer>] - Giveback Attempts Minutes
Selects configuration information for nodes that have the specified giveback attempt time setting.

[-propagate {true|false}] - Propagate Status via Mailbox
Selects configuration information for nodes that have the specified setting for propagation of status through Storage Failover mailboxes.

[-read-interval <integer>] - Node Status Read Interval (secs)
Selects configuration information for nodes that have the specified status read interval setting.

[-write-interval <integer>] - Node Status Write Interval (secs)
Selects configuration information for nodes that have the specified status write interval setting.

[-onreboot {true|false}] - Takeover on Reboot Enabled
Selects configuration information for nodes that have the specified takeover-on-reboot setting.

[-delay-seconds <integer>] - Delay Before Auto Giveback (secs)
If this parameter is specified, the command displays information only about the node or nodes that have the specified delay for auto giveback.

[-hwassist {true|false}] - Hwassist Enabled
Selects configuration information for nodes that have the specified hardware-assisted takeover setting.

[-hwassist-partner-ip <text>] - Partner's Hwassist IP
Selects configuration information for nodes that have the specified partner IP setting for hardware-assisted takeovers.

[-hwassist-partner-port <integer>] - Partner's Hwassist Port
Selects configuration information for nodes that have the specified partner port setting for hardware-assisted takeovers.

[-hwassist-health-check-interval <integer>] - Hwassist Health Check Interval (secs)
Selects configuration information for nodes that have the specified health check interval setting for hardware-assisted takeovers.

[-hwassist-retry-count <integer>] - Hwassist Retry Count
Selects configuration information for nodes that have the specified retry count (in seconds) for hardware-assisted takeovers.

[-mode {ha|non_ha}] - HA Mode
If this parameter is specified, the command displays information only about the node or nodes that have the specified HA mode.

[-bypass-takeover-optimization {true|false}] - Bypass Takeover Optimization Enabled
Selects configuration information for nodes that have the specified setting for bypass takeover optimization (true means that optimized operator-initiated planned takeover is bypassed, false means that it is enabled). Operator-initiated planned takeover is optimized when SFO aggregates are relocated serially to the partner prior to takeover. This reduces client outage.

### Examples
The following example displays detailed information about the internal options for storage failover on a node named node2:

```
cluster1::*> storage failover internal-options show -node node2

Node: node2
  Auto Giveback Enabled: false
  Check Partner Enabled: true
  Takeover Detection Time (secs): 15
  Takeover On Failure Enabled: true
  Takeover On Panic Enabled: false
```
storage failover mailbox-disk commands

Display the status of storage failover mailbox disks

Mailbox disks are part of root aggregate. High Availability related information is written persistently on mailbox disks. This directory contains command to display information related to local and partner mailbox disks.

storage failover mailbox-disk show

Display information about storage failover mailbox disks

Availability: This command is available to cluster administrators at the advanced privilege level.

Description

The storage failover mailbox-disk show command lists the mailbox disks that are used by storage failover. The command displays the following information:

• Node name
• Whether the mailbox disk is owned by the local node or by its partner
• Disk name
• Disk universal unique identifier (UUID)

This command is available only at the advanced privilege level and higher.

Parameters

{ [-fields <fieldname>, ...]  
  If -fields <fieldname>,... is used, the command displays only the specified fields.
  | [-instance ]  
  If this parameter is used, the command displays detailed information about all entries.
  [-node (<nodename>|local)] - Node
  Selects the mailbox disks that are associated with the specified node.
  [-location (local|partner|tertiary)] - Mailbox Owner
  Selects the mailbox disks that have the specified relationship to the node.
  [-diskindex <integer>] - Mailbox Disk Index
  Selects the mailbox disk that has the specified index number.
[-diskname <text>] - Mailbox Disk Name
Selects the mailbox disks that match the specified disk name.

[-diskuuid <text>] - Mailbox Disk UUID
Selects the mailbox disks that match the specified UUID.

[-physical-location {local|partner|mediator}] - Mailbox Disk Physical Location
Selects the mailbox disks that match the specified physical location.

[-location-id <nvramid>] - System ID of the Node where the Disk is Attached
Selects the mailbox disks that match the specified location-id.

[-location-name <text>] - Mailbox Disk Location
Selects the mailbox disks that match the specified location-name.

### Examples
The following example displays information about the mailbox disks on a node named node1:

```
cluster1::*> storage failover mailbox-disk show -node node1
Node    Location  Index Disk Name     Physical Location     Disk UUID
------- --------- ----- ------------- ------------------ --------------------
node1   local         0 1.0.4         local         20000000:8777E9D6:
local   1 1.0.6         partner     20000000:8777E9DE:
partner 0 1.0.1         local         20000000:877BA634:
partner 1 1.0.2         partner     20000000:8777C1F2:
```

### storage failover progress-table commands
Display the storage failover progress table

### storage failover progress-table show
Display status information about storage failover operations

**Availability:** This command is available to cluster administrators at the advanced privilege level.

**Description**
The `storage failover progress-table show` displays status information about storage-failover operations. This information is organized in a resource table. The command displays the following information:

- Node name
- Resource-entry index number
- Resource-entry name
- Resource-entry state
- Resource-entry failure code
- Resource-entry time delta

This command is available only at the advanced privilege level and higher.

**Parameters**
```
[-fields <fieldname>, ...]
```
If -fields <fieldname>, ... is used, the command will only displays only the specified fields.
| [-instance ]}
If this parameter is used, the command displays detailed information about all entries.
[-node {<nodename>|local}] - Node
Selects the status information for the specified node.
[-index <integer>] - Resource Table Index
Selects the status information for the specified index number.
[-entryname <text>] - Resource Table Entry Name
Selects the status information for the specified entry name.
[-state <text>] - Resource Table Entry State
Selects the status information for the specified state. Possible values include UP, START_RUNNING,
START_DONE, START_FAILED, STOP_RUNNING, STOP_FAILED, TAKEOVER_BARRIER, and
ONLY_WHEN_INITD.
[-failurecode <text>] - Entry Failure Code
Selects the status information for the specified failure code. Possible values include OK, FAIL,
FAIL_ALWAYS, HANG, PANIC, and VETO.
[-timedelta <integer>] - Entry Time Delta
Selects the status information for the specified time delta.
Examples
The following example displays the entire storage-failover resource table:
cluster1::*> storage failover progress-table show

storage firmware commands
Download disk, ACP Processor and shelf firmware

storage firmware download
Download disk, ACP processor and shelf firmware
Availability: This command is available to cluster administrators at the advanced privilege level.
840

Commands: Manual Page Reference


**Description**
The `storage firmware download` command downloads ACP processor, disk and shelf firmware to a specified node.

Use the `storage disk firmware update` command to install downloaded disk firmware.

Use the `system node run local storage download shelf` command to install downloaded disk shelf module firmware.

Use the `system node run local storage download acp` command to install downloaded ACP processor firmware.

**Parameters**

- `-node <nodename>|local` - Node
  This specifies the node to which the firmware is to be downloaded.

- `-package-url <text>` - Package URL
  This specifies the path to the firmware package.

  The following URL protocols are supported: ftp, http, and tftp.

**Examples**
The following example downloads a disk firmware package with the path `ftp://example.com/fw/disk-fw-1.2.LOD.zip` to a node named `node1`:

```
cluster1::> storage firmware download -node node1 -package-url ftp://example.com/fw/disk-fw-1.2.LOD.zip
```

---

**storage iscsi-initiator commands**

Configure the iSCSI initiator

The `storage iscsi-initiator` commands configure the list of iSCSI targets. These commands are only supported on high-availability shared-nothing virtualized platforms.

**storage iscsi-initiator add-target**

Add an iSCSI target

**Availability:** This command is available to `cluster` administrators at the `advanced` privilege level.

**Description**
The `storage iscsi-initiator add-target` command adds an iSCSI target to a node's list of targets. This command is only supported on high-availability shared-nothing virtualized platforms.

**Parameters**

- `-node <nodename>|local` - Node
  Specifies the name of the Data ONTAP node to which the iSCSI target will be added.

- `-label <text>` - User Defined Identifier
  Specifies a label for the target to be added.
-target-type {external|mailbox|partner} - Target Type

Specifies the type of the target. It is used by the node to determine how to use the LUNs. There are three target types:

- partner - The partner target should belong to the node's HA partner. This allows the node to access its partner's disks.
- mailbox - A mailbox target's LUNs are used exclusively as HA mailboxes.
- external - External targets' LUNs can be used by the node but do not play a role in HA.

-target-portal <text> - Target Portal

Specifies the target's IP address and listening TCP port. The port is not required if it is the default iSCSI port (3260). Examples of correct target portals are 10.0.0.2 and 10.0.0.2:860.

-target-name <text> - iSCSI Name

Specifies the iSCSI target name such as an IQN (iSCSI qualified name).

[-status-admin {down|up}] - Administrative Status (default: up)

Use to specify whether the initial administrative status of the connection is up or down. The default setting is up.

Examples

The following example adds and connects to an iSCSI target from the specified node.

```
cluster1:/> storage iscsi-initiator add-target -node node1
   -label target1 -target-type external
   -target-portal 10.0.0.2:860
   -target-name iqn.2012-06.com.bsdctl:target0
```

storage iscsi-initiator connect

Connect to an iSCSI target

Availability: This command is available to cluster administrators at the advanced privilege level.

Description

The storage iscsi-initiator connect command connects a node to the specified target. This command is only supported on high-availability shared-nothing virtualized platforms.

Parameters

- **-node <nodename>|local** - Node
  
  Specifies the name of the Data ONTAP node to which the iSCSI target will be connected.

- **-[target-type {external|mailbox|partner}]** - Target Type
  
  Selects targets with the specified target type.

- **-label <text>** - User Defined Identifier
  
  Specifies the label of the target to connect to.

Examples

The following example adds and connects to an iSCSI target from the specified node.

storage iscsi-initiator disconnect

Disconnect from an iSCSI target

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

**Description**
The `storage iscsi-initiator disconnect` command disconnects a node from the specified target. This command is only supported on high-availability shared-nothing virtualized platforms.

**Parameters**
- `-node {<nodename>|local}` - Node
  
  Specifies the name of the Data ONTAP node from which the iSCSI target will be disconnected.

- `[-target-type {external|mailbox|partner}]` - Target Type
  
  Selects targets with the specified target type.

- `-label <text>` - User Defined Identifier
  
  Specifies the label of the target to disconnect from.

**Examples**
The following example adds and connects to an iSCSI target from the specified node.

```
cluster1:~*> storage iscsi-initiator disconnect -node node1
-label target1
```
storage iscsi-initiator show

Display the iSCSI targets

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
The storage iscsi-initiator show displays the list of iSCSI targets configured for each Data ONTAP node in the cluster. This command is only supported on high-availability shared-nothing virtualized platforms.

Parameters

{-fields <fieldname>, ...}
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

{-instance}}
If you specify the -instance parameter, the command displays detailed information about all fields.

{-node <nodename>|local]} - Node
Represents the name of the Data ONTAP node for which information is to be displayed. If this parameter is not specified, the command displays information about all nodes in the cluster.

{-target-type {external|mailbox|partner]} - Target Type
Selects targets with the specified target type.

{-label <text>} - User Defined Identifier
Selects targets with the specified label.

{-target-portal <text>} - Target Portal
