exit

Quit the CLI session

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The exit command ends the current CLI session.

Examples
The following example ends the current CLI session:

```
cluster1:/> exit
Goodbye
```
history

Show the history of commands for this CLI session

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The history command displays the command history of the current CLI session. A numeric ID precedes each command. Use this number with the redo command to re-execute that history item.

Examples
The following example displays the command history of the current CLI session:

cluster1::> history
  1  vserver show
  2  man volume show
  3  volume delete -vserver vs0 -volume temporary2
  4  volume modify { -volume temp* } -state offline
cluster1::> redo 3

Related references
redo on page 3

man

Display the online manual pages

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The man command displays the manual page of the command you specify. If you do not specify a command, command displays the man page index.

Parameters
[<text>] - Valid CLI command
The command for which you'd like to see the manual page. The syntax of the command is the same as the command itself. The man command supports abbreviations and tab completion of the command name.

Examples
The following example displays the manual page for the storage aggregate create command.

cluster1::> man sto aggr cre

That example could also have been fully specified as:

cluster1::> man storage aggregate create
redo

Execute a previous command

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The redo command re-executes a command that has been executed previously in the current CLI session. Specify a previously run command using:

- A string that matches part of a previous command. For example, if the only volume command you have run is `volume show`, enter `redo vol` to re-execute the command.
- The numeric ID of a previous command, as listed by the history command. For example, enter `redo 4` to re-execute the fourth command in the history list.
- A negative offset from the end of the history list. For example, enter `redo -2` to re-execute the command that you ran two commands ago.

Parameters
[<text>] - String, Event Number, or Negative Offset
Use this parameter to specify a string, a numeric ID from the command history, or a negative number that identifies the command to be re-executed.

Examples
The following example re-executes command number 10 in the command history:

```
cluster1::> redo 10
```

history on page 2

rows

Show/Set the rows for the CLI session

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The rows command displays the number of rows that can be displayed in the current CLI session before the interface pauses output. If you do not set this value, it adjusts automatically based on the actual height of your terminal. If the actual height is undefined, the default number of rows is 24.

Specify a number to set the number of rows that can be displayed. Setting this value manually disables auto-adjustment. Specify zero (0) to disable pausing.

You can also set this value using the `set -rows` command.
Parameters

[<integer>] - Number of Rows the Screen Can Display

Use this parameter to specify the number of rows your terminal can display.

Examples

The following example displays the current number of rows, then resets the number of rows to 48:

```
cluster1::> rows
36
cluster1::> rows 48
```

*set* on page 4

---

**set**

Display/Set CLI session settings

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

**Description**

The *set* command changes attributes of the user interface.

**Parameters**

*[-privilege <PrivilegeLevel>] - Privilege Level*

Use this parameter to specify the privilege level of the command session. Possible values are

- admin - Used for routine system management commands
- advanced - Used for infrequent, dangerous, or complicated commands
- diagnostic - Used for detailed diagnostic commands that are used only by support personnel

*[-confirmations (on|off)] - Confirmation Messages*

Use this parameter with the value *on* to specify that the interface prompt for confirmation before executing potentially dangerous commands. Use this parameter with the value *off* to specify that the interface not prompt for confirmation, even before potentially dangerous commands execute. The default setting is *on*.

*[-showallfields (true|false)] - Show All Fields*

Use this parameter with the value *true* to specify that the interface display all field columns when displaying tabular output. Use this parameter with the value *false* to specify that the interface display only selected columns. The default setting is *false*.

*[-showseparator <text>] - Show Separator*

Use this parameter to specify the characters to use as the field separator. The field separator is used between field columns when *-showallfields* is set to "true". The separator can be from one to three characters in length. When specifying the separator, enclose it in quotation marks (*"*). Set the separator to one or more spaces to disable this feature.
- **active-help** *(true|false)* - Active Help
  Use this parameter with the value `true` to specify that pressing the question mark (?) key is sufficient to execute a help request. Use this parameter with the value `false` to specify that you must press the Return key after the question mark key to execute a help request. The default setting is `true`.

- **units** *(auto|raw|B|KB|MB|GB|TB|PB)* - Data Units
  Use this parameter to specify the default units used when reporting data sizes. Possible values are:
  - `auto` - Auto-scale data size for human-readable output
  - `raw` - Bytes without unit designation
  - `B` - Bytes
  - `KB` - Kilobytes (1024 bytes, aka kibibytes)
  - `MB` - Megabytes (KB x 1024, aka mebibytes)
  - `GB` - Gigabytes (MB x 1024, aka gibibytes)
  - `TB` - Terabytes (GB x 1024, aka tebibytes)
  - `PB` - Petabytes (TB x 1024, aka pebibytes)
  The default setting is `auto`.

- **rows** *(<integer>)* - Pagination Rows ('0' disables)
  Use this parameter to specify the number of rows that can be displayed in the current CLI session before the interface pauses output. If you do not set this value, it adjusts automatically based on the actual height of your terminal. If the actual height is undefined, the default number of rows is 24.
  Setting this value manually disables auto-adjustment. Specify zero (0) to disable pausing.
  You can also set this value using the `rows` command.

- **vserver** *(<text>)* - Default Vserver
  Use this parameter to specify the name of the Vserver to use as the default value for the `-vserver` parameter of commands.
  WARNING: Vserverized commands that only have a single required parameter, which is the `<userinput>-vserver<userinput>`, allow the Vserver to be specified positionally, without `<userinput>-vserver<userinput>` preceding it. Due to this, care must be take when using CLI commands that do not require the `<userinput>-vserver<userinput>` parameter. For example, using the "vserver nfs delete *" command will ignore the "set -vserver" value as the parser considers the "*" to be the Vserver.

- **node** *(<text>)* - Default Node
  Use this parameter to specify the name of the node to use as the default value for the `-node` parameter of commands.

- **stop-on-error** *(true|false)* - Stop On Error
  Use this parameter with the value `true` to specify that continuing commands should stop if they encounter an error. Use this parameter with the value `false` to specify that continuing commands should continue if they encounter an error.

- **prompt-timestamp** *(above|inline|none)* - Display Prompt Timestamp
  Print the current date and time as a part of the prompt. The possible values are
  - `above` - print the timestamp using the system timestamp format on the line above the remainder of the prompt.
• **inline** - print the timestamp using the system timestamp format at the beginning of the line with the remainder of the prompt.

• **none** - do not print the timestamp.

The default value is **none**.

---

**Examples**

The following example sets the privilege level to advanced.

```bash
cluster1::> set -privilege advanced

Warning: These advanced commands are potentially dangerous; use them only when directed to do so by NetApp personnel.

Do you wish to continue? (y or n): y

cluster1::>
```

The following examples cause all columns to be shown in output rows, with a comma used as the field separator.

```bash
cluster1::> set -showallfields true
cluster1::> set -showseparator ","

cluster1::> network port show

(rows on page 3)
top

Go to the top-level directory

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The top command changes the current working directory of the command prompt to the top-level command directory.

Examples
The following example returns the command prompt from the storage aggregate directory to the top-level directory:

```
cluster1::storage aggregate> top
cluster1::>
```

storage aggregate on page 820

up

Go up one directory

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The up command, which can also be specified as two dots (..), changes the current working directory of the command prompt to the directory that is up one level in the command hierarchy.

Examples
The following example takes the command prompt up one level from the storage aggregate directory:

```
cluster1::storage aggregate> up
cluster1::storage>
```

application commands

Display and manage applications
application provisioning commands
Manage application provisioning

application provisioning config commands
Manage configuration for application provisioning

application provisioning config modify
Modify options for application provisioning
Availability: This command is available to cluster administrators at the advanced privilege level.

Description
This command modifies the options for application provisioning operations.

Parameters
- `-is-mixed-storage-services-allowed {true|false}` - Is Mixed Storage Services Allowed
  Specifies whether mixed cost storage services are allowed for provisioning placement. If the value of this parameter is `false`, only the aggregates closest to the performance requirements of the storage service are used. If the value of this parameter is `true`, all aggregates with sufficient performance are considered. The initial value for this option is `false`.

Examples
```
cluster1::*> application provisioning config modify -is-mixed-storage-services-allowed true
```

application provisioning config show
Display options for application provisioning
Availability: This command is available to cluster administrators at the advanced privilege level.

Description
This command displays options for application provisioning.

Examples
```
cluster1::*> application provisioning config show
Is Mixed Storage Services Allowed: false
```

autobalance commands
The autobalance directory
autobalance aggregate commands

Auto Balance Aggregate

autobalance aggregate show-aggregate-state

Display the Auto Balance Aggregate state for an aggregate

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
The `autobalance aggregate show-aggregate-state` command displays information about an aggregate state that is considered by the Auto Balance Aggregate feature.

Parameters

```
[-fields <fieldname>,...]
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

[-instance ]
If you specify the -instance parameter, the command displays detailed information about all fields.
```

```
[-node {<nodename>|local}] - Node Name
If this parameter is specified, the display will be limited to only those aggregates with a node that matches the specified value.

[-aggregate <aggregate name>] - Name of the Aggregate
If this parameter is specified, the display will be limited to only that aggregate with a name that matches the specified value.

[-total-size <integer>[KB|MB|GB|TB|PB]] - Total Size of the Aggregate
If this parameter is specified, the display will be limited to only those aggregates with a total-size that matches the specified value.

[-used-size <integer>[KB|MB|GB|TB|PB]] - Used Size of the Aggregate
If this parameter is specified, the display will be limited to only those aggregates with a used-size that matches the specified value.

[-aggregate-unbalanced-threshold <integer>[KB|MB|GB|TB|PB]] - Threshold When Aggregate Is Considered Unbalanced
If this parameter is specified, the display will be limited to only those aggregates with a threshold that matches the specified value.

[-outgoing-size <integer>[KB|MB|GB|TB|PB]] - Size of Outgoing Volumes in the Aggregate
If this parameter is specified, the display will be limited to only those aggregates with an outgoing-size that matches the specified value. Outgoing size will be equal to the total size of the volumes that move away from each one of those aggregate.

[-incoming-size <integer>[KB|MB|GB|TB|PB]] - Size of Incoming Volumes in the Aggregate
If this parameter is specified, the display will be limited to only those aggregates with an incoming-size that matches the specified value. Incoming size will be equal to the total size of the volumes that move towards to each one of those aggregates.

[-raidtype {raid_tec|raid_dp|raid4}] - RAID Type
If this parameter is specified, the display will be limited to only those aggregates with a raidtype that matches the specified value.
[-home-cluster <UUID>] - Home Cluster ID
If this parameter is specified, the display will be limited to only those aggregates with a home-cluster ID that
matches the specified value.

[-is-hybrid {true|false}] - Aggregate Is a Hybrid
If this parameter is specified as true, the display will be limited to only hybrid aggregates. If the parameter is
specified as false, the display will be limited to only non-hybrid aggregates.

[-is-incoming-volume-thin {true|false}] - An Incoming Volume Is Thin
When you use thin provisioning for a volume, it can run out of space even if it has not yet consumed its
nominal size and you should carefully monitor space utilization to avoid unexpected errors due to the volume
running out of space. If this parameter is specified as true, the display will be limited to only those aggregates
which are the target of a move of thin volume. If the parameter is specified as false, the display will be limited
to only those aggregates which are not the target of a move of thin volume.

[-is-balanceable {true|false}] - Is Balanceable
If this parameter is specified as true, the display will be limited to only balanceable aggregates. If the
parameter is specified as false, the display will be limited to only non-balanceable aggregates.

[-is-move-target {true|false}] - Aggregate Is a Volume Move Target
If this parameter is specified as true, the display will be limited to only those aggregates which are target of a
volume move. If the parameter is specified as false, the display will be limited to only those aggregates which
are not the target of a volume move.

[-attributes <text>, ...] - Aggregate Attributes
If this parameter is specified, the display will be limited to only those aggregates with attributes that matches
the specified values.

[-aggregate-available-threshold (<integer> [KB|MB|GB|TB|PB])] - Threshold When Aggregate Is
Considered Balanced
If this parameter is specified, the display will be limited to only those aggregates which meet the specified
threshold to be considered as balanced.

### Examples
The following example displays information about the state for all aggregates in the cluster.

```
cluster1:~*> autobalance aggregate show-aggregate-state
Aggregate: aggr0
  Total Size: 4.78GB
  Used Size: 4.56GB
  Outgoing Size: 0B
  Incoming Size: 0B
Aggregate Used Space Threshold: 3.34GB
Aggregate Available Space Threshold: 1.91GB
RAID Type: raid_dp
Home Cluster ID: edf0379b-16da-11e6-aa3c-0050568558c2
Attributes: CFO
Excluded Mroot

Aggregate: aggr_1
  Total Size: 12.61GB
  Used Size: 111.6MB
  Outgoing Size: 0B
  Incoming Size: 0B
Aggregate Used Space Threshold: 8.83GB
Aggregate Available Space Threshold: 5.04GB
RAID Type: raid4
Home Cluster ID: edf0379b-16da-11e6-aa3c-0050568558c2
Attributes: Excluded
```

The following example displays information about all entries of the aggregate state, for all aggregates in the cluster.
### Autobalance Aggregate Commands

**autobalance aggregate show-unbalanced-volume-state**

Display the Auto Balance Aggregate state for a volume

**Availability:** This command is available to cluster administrators at the *advanced* privilege level.

**Description**

The `autobalance aggregate show-unbalanced-volume-state` command displays information about a volume that is considered by the Auto Balance Aggregate feature.

**Parameters**

```
{-fields <fieldname>,...}
```

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

```
{| -instance }
```

If you specify the `-instance` parameter, the command displays detailed information about all fields.

```
[-node <nodename> | local] - Node Name
```

If this parameter is specified, the display will be limited to only those volumes with a node that matches the specified value.

```
[-DSID <integer>] - DSID of the Last Volume Queried
```

If this parameter is specified, the display will be limited to only those volumes with a DSID that matches the specified value.

```
[-aggregate <aggregate name>] - Aggregate
```

If this parameter is specified, the display will be limited to only those volumes with an aggregate name that matches the specified value.

[-volume-name <text>] - Name of the Volume
   If this parameter is specified, the display will be limited to only that volume with a name that matches the specified value.

[-last-threshold-crossed-time <MM/DD/YYYY HH:MM:SS>] - Last Time Threshold Crossed
   If this parameter is specified, the display will be limited to only those volumes with a threshold crossing time that matches the specified value.

[-last-placed-time <MM/DD/YYYY HH:MM:SS>] - Last Time Volume Was Moved
   If this parameter is specified, the display will be limited to only those volumes with a last time they have been moved that matches the specified value.

[-is-moving {true|false}] - Is Volume Currently Moving
   If this parameter is specified as true, the display will be limited to only the moving volumes. If the parameter is specified as false, the display will be limited to only the non-moving volumes.

[-is-quiesced {true|false}] - Is Volume Quiesced
   If this parameter is specified as true, the display will be limited to only the quiesced volumes. If the parameter is specified as false, the display will be limited to only the non-quiesced volumes.

[-total-footprint <integer>[KB|MB|GB|TB|PB]] - Total Size of the Volume
   If this parameter is specified, the display will be limited to only those volumes with a total footprint that matches the specified value.

[-attributes <text>,...] - Volume's Attributes
   If this parameter is specified, the display will be limited to only those volumes with attributes that matches the specified value.

[-last-checked <MM/DD/YYYY HH:MM:SS>] - Last Time Volume State Was Checked
   If this parameter is specified, the display will be limited to only those volumes with a last time their state was checked that matches the specified value.

**Examples**

The following example display information about all of the unbalanced volumes that the Auto Balance Aggregate feature is aware of.

```
cluster1::*> autobalance aggregate show-unbalanced-volume-state
   Last Checked On: 3/13/2014 14:32:01
       Volume: ro10
       Footprint: 20.20MB
   Last Time Over IOPS Threshold: 3/12/2014 16:20:18
       Last Placed: 3/11/2014 10:16:04
       Attributes: Over IOPS Threshold
                     Stabilizing

       Volume: test
       Footprint: 20.20MB
   Last Time Over IOPS Threshold: 3/12/2014 16:20:18
       Last Placed: 3/11/2014 10:16:42
       Attributes: Over IOPS Threshold
                     In Mirror
                     Stabilizing
```

The following example displays all of the information that the Auto Balance Aggregate feature has collected for all of the unbalanced volumes it is aware of.

```
cluster1::*> autobalance aggregate show-unbalanced-volume-state -instance
   Node Name: cluster-1-01
   DSID of the Last Volume Queried: 1025
   Aggregate: aggr_1
   Name of the Volume: ro10
   Last Time Threshold Crossed: 3/12/2014 16:20:18
```
autobalance aggregate config commands

Auto Balance Aggregate configuration

autobalance aggregate config modify

Modify the Auto Balance Aggregate feature configuration

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
The autobalance aggregate config modify command allows the user to customize the parameters that determine when volumes should be considered for automatic move or recommendation by the Auto Balance Aggregate feature.

Parameters

[-is-enabled {true|false}] - Is the Auto Balance Aggregate Feature Enabled

This specifies whether the Auto Balance Aggregate feature is enabled and running.

[-aggregate-unbalanced-threshold-percent <integer>] - Threshold When Aggregate Is Considered Unbalanced (%)

This specifies the space used threshold percentage that will cause the Auto Balance Aggregate feature to consider an aggregate as unbalanced.

[-aggregate-available-threshold-percent <integer>] - Threshold When Aggregate Is Considered Balanced (%)

This specifies the threshold percentage which will determine if an aggregate is a target destination for a move. The Auto Balance Aggregate feature will attempt to move volumes from an unbalanced aggregate until it is under this percentage.

Examples
The following example displays a modification for the default configuration of the Auto Balance Aggregate feature

```
cluster1:*> autobalance aggregate config show
Is the Auto Balance Aggregate Feature Enabled: false
Threshold When Aggregate Is Considered Unbalanced (%): 70
Threshold When Aggregate Is Considered Balanced (%): 40

cluster1:*> autobalance aggregate config modify -is-enabled true
cluster1:*> autobalance aggregate config show
```

Is the Auto Balance Aggregate Feature Enabled: true  
Threshold When Aggregate Is Considered Unbalanced (%): 70  
Threshold When Aggregate Is Considered Balanced (%): 40

At the diagnostic level, there are additional modifiable parameters.

```bash
cluster1::*> autobalance aggregate config show
Is the Auto Balance Aggregate Feature Enabled: false
Mode of the Auto Balance Aggregate Feature: recommend
Polling Interval: 3600
Threshold When Aggregate Is Considered Unbalanced (%): 70
Threshold When Aggregate Is Considered Balanced (%): 40
Volume Operations Threshold (IOPS): 100
Volume Operations Threshold Not Exceeded for Duration: 24
Volume Not Moved Again for Duration: 48

cluster1::*> autobalance aggregate config modify -mode auto -polling-interval 4000

cluster1::*> autobalance aggregate config show
Is the Auto Balance Aggregate Feature Enabled: false
Mode of the Auto Balance Aggregate Feature: auto
Polling Interval: 4000
Threshold When Aggregate Is Considered Unbalanced (%): 70
Threshold When Aggregate Is Considered Balanced (%): 40
Volume Operations Threshold (IOPS): 100
Volume Operations Threshold Not Exceeded for Duration: 24
Volume Not Moved Again for Duration: 48
```

**autobalance aggregate config show**
Display the Auto Balance Aggregate feature configuration

**Availability:** This command is available to cluster administrators at the advanced privilege level.

**Description**
The `autobalance aggregate config show` command displays information about parameters that determine when volumes should be considered for automatic move or recommendation by the Auto Balance Aggregate feature.

**Examples**
The following example displays the default configuration for the Auto Balance Aggregate feature

```bash
cluster1::*> autobalance aggregate config show
Is the Auto Balance Aggregate Feature Enabled: false
Threshold When Aggregate Is Considered Unbalanced (%): 70
Threshold When Aggregate Is Considered Balanced (%): 40

At the diagnostic level, the output displays the information below.

```
Is the Auto Balance Aggregate Feature Enabled: false
Mode of the Auto Balance Aggregate Feature: recommend
Polling Interval: 3600
Threshold When Aggregate Is Considered Unbalanced (%): 70
Threshold When Aggregate Is Considered Balanced (%): 40
Volume Operations Threshold (IOPS): 100
Volume Operations Threshold Not Exceeded for Duration: 24
Volume Not Moved Again for Duration: 48
```

14
Cluster Commands

Manage clusters

The cluster commands enable you to create and manage Data ONTAP 8 clusters.

cluster add-node

Expand the cluster by discovering and adding new nodes

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The cluster add-node command discovers and adds new nodes to the cluster. When the -node-count parameter is specified, the command attempts to add that many nodes to the cluster. The -node-ip parameter can be specified to directly add a node. The -cluster-ips parameter can be specified to directly add one or more nodes in parallel. Only one of the -node-count, -node-ip and -cluster-ips parameters can be provided. The system node show-discovered command displays all the nodes discovered on the local network.

Note: The node-count parameter is deprecated and may be removed in a future release of Data ONTAP. Use the -cluster-ips parameter instead.

Note: The node-ip parameter is deprecated and may be removed in a future release of Data ONTAP. Use the -cluster-ips parameter instead.

Parameters

{-cluster-ips <IP Address>,} - List of Cluster Interface IP Addresses of the Nodes Being Added

This parameter contains a comma separated list of cluster interface IP addresses of the nodes in the cluster you are creating. All the nodes specified in the list will be added to the cluster.

|-retry [true] - Retry a failed cluster add-node operation

Use this parameter to retry the most recently failed cluster add-node command with the originally specified parameters. Retry is not supported if the cluster add-node command was originally run with either the -node-count or -node-ip parameters.

| -node-count <integer> - (DEPRECATED)-Number of Nodes Being Added

Number of nodes to be added to the cluster. If fewer nodes are discovered, all the discovered nodes are added to the cluster and the command will fail since there are fewer nodes than specified. If more nodes are found than the number specified, the command will fail because there is no way to determine which nodes you intend to add to the cluster.

Note: The -node-count parameter is supported on non-shared architecture platforms only.

|-node-ip <IP Address> - (DEPRECATED)-Cluster IP Address of Node

Cluster IP address of the node to add. When this parameter is provided, the command directly adds the node.

[-node-names <text>,...] - List of Node Names

This parameter contains a comma separated list of node names of all the nodes in the cluster you are creating. The node names must have an one to one correspondence with -cluster-ips parameter. The names provided will be used to rename the nodes once they are added to the cluster.
[\texttt{--foreground \{true|false\}}] - Foreground Process

When set to \texttt{false} the command runs in the background as a job. The default is \texttt{true}, which causes the command to return after the operation completes.

[\texttt{--allow-mixed-version-join \{true\}}] - Allow a Node At a Different Version to Join Cluster

This parameter allows nodes with different, but compatible versions of Data ONTAP to be added to the cluster. A Data ONTAP best practice is to add nodes to the cluster that are of the same Data ONTAP version as the nodes in the cluster, but that may not always be possible.

\begin{table}
\centering
\begin{tabular}{|l|}
\hline
Examples \\
\hline
The following example adds a node using \texttt{--cluster-ips}: \\
\texttt{cluster1::> cluster add-node --cluster-ips 1.1.1.1, 2.2.2.2} \\
Use the 'cluster add-node-status' command to see the progress of the add-node operation. \\
\hline

The following example adds 3 nodes using \texttt{--node-count}. \\
\texttt{cluster1::> cluster add-node --node-count 3} \\
[Job 22] Job succeeded. \\
\hline
\end{tabular}
\end{table}

system node show-discovered on page 1276

\texttt{cluster create} on page 17

\textbf{cluster add-node-status}

Show cluster expansion progress

**Availability:** This command is available to \texttt{cluster} administrators at the \texttt{admin} privilege level.

**Description**

The \texttt{cluster add-node-status} command displays the progress of the node joining a cluster initiated by using the \texttt{cluster create} command or the \texttt{cluster add-node} command.

**Parameters**

\begin{itemize}
\item \texttt{\{--fields <fieldname>, ...\}} \\
If you specify the \texttt{--fields <fieldname>, ...} parameter, the command output also includes the specified field or fields. You can use ‘-fields ?’ to display the fields to specify.
\item \texttt{\{--instance\}} \\
If you specify the \texttt{--instance} parameter, the command displays detailed information about all fields.
\item \texttt{--node-uuid <UUID>} - Node UUID \\
Select the node that match the specified node UUID.
\item \texttt{--node-name <text>} - Node Name \\
Select the nodes that match the specified node name.
\item \texttt{--cluster-ip <IP Address>} - IP Address of a Cluster Interface of Node \\
Select the nodes that match the specified cluster IP.
\end{itemize}
[-status <Cluster Operation Status>] - The Status of Current Task Being Performed
Select the nodes that match the specified status. This status shows whether the operation is ongoing or complete with success or failure. The various phases that a node goes through are node-initialization, joining-cluster, service-startup, post-cluster-setup and success or failure.

[-failure-msg <text>] - Error Reason
Select the nodes that match the specified error string.

[-last-updated <MM/DD/YYYY HH:MM:SS>] - Last Updated
The date/time stamp of the last update to the status.

Examples
The following example shows the progress of a node add operation:

cus1::> cluster add-node-status

<table>
<thead>
<tr>
<th>Node Name</th>
<th>Node IP</th>
<th>Status</th>
<th>Error Reason</th>
</tr>
</thead>
<tbody>
<tr>
<td>node1</td>
<td>1.1.1.1</td>
<td>success</td>
<td>-</td>
</tr>
</tbody>
</table>

cluster create
Create a cluster

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The `cluster create` command creates a cluster with one or more nodes. When the `-node-count` parameter is specified, the command attempts to add that many nodes to the cluster. The `-cluster-ips` parameter can be specified to add one or more nodes in parallel. Only one of the `-node-count` and `-cluster-ips` parameters can be provided.

Note that single-node clusters do not require configuring the cluster network. A cluster network interface must be configured before other nodes can join the cluster.

Note: The `node-count` parameter is deprecated and may be removed in a future release of Data ONTAP. Use the `-cluster-ips` parameter instead.

Parameters
[-license <License Code V2>] - (DEPRECATED)-Base License

Note: This parameter is deprecated and may be removed in a future release of Data ONTAP.
Use this optional parameter to specify the base license for the cluster. Obtain this value from your sales or support representative.

-`clusternametext>` - Cluster Name
Use this parameter to specify the name of the cluster you are creating.

- The name must contain only the following characters: A-Z, a-z, 0-9, "," or ".".
- The first character must be one of the following characters: A-Z or a-z.
The last character must be one of the following characters: A-Z, a-z or 0-9.
The maximum supported length is 44 characters.
The system reserves the following names: "all", "cluster", "local" and "localhost".

| [-cluster-ips <IP Address>, ...] - List of Cluster Interface IP Addresses of the Nodes Being Added
  This parameter contains a comma separated list of cluster interface IP addresses of the nodes in the cluster you are creating. All the nodes specified in the list will be added to the cluster.

| [-node-count <integer>] - (DEPRECATED)-Node Count
  Use this parameter to specify the number of nodes in the cluster you are creating.
  • -node-count parameter is supported on non-shared architecture platforms only.

| [-node-names <text>, ...] - List of Node Names
  This parameter contains a comma separated list of node names of all the nodes in the cluster you are creating.
  The node names must have an one to one correspondence with -cluster-ips parameter. The names provided will be used to rename the nodes once they are added to the cluster.

| -retry {true} - Retry a failed cluster create operation
  Use this parameter to retry the most recently failed cluster create command with the originally specified parameters. Retry is not supported if the cluster create command was originally run with either the -node-count or -node-ip parameters.

Examples
The following example creates a cluster named cluster1

```
cluster1::> cluster create -clustername cluster1
```

The following example creates a cluster named cluster1 with node-count 4 on a non-shared architecture platform.

```
cluster1::> cluster create -clustername cluster1 -node-count 4
```

cluster join
(DEPRECATED)-Join an existing cluster using the specified member's IP address or by cluster name
Availability: This command is available to cluster administrators at the admin privilege level.

Description
Note: This command is deprecated and may be removed in a future release of Data ONTAP. Use cluster add-node from a node in the cluster instead.
The cluster join command adds a node to an existing cluster. Use the cluster create command to create a cluster if one does not already exist.
Note that a cluster network interface must be configured for the cluster before other nodes can join the cluster.
Parameters

\{-clusteripaddr <IP Address>\} - IP Address of a Cluster Interface from a Node in the Cluster

Use this parameter to specify the IP address of a cluster interface. This must be the IP address of a cluster interface of a node that is already in the cluster. This parameter is mutually exclusive with the \{-cluster-name\} parameter.

\{-cluster-name <text>\} - (DEPRECATED)-Cluster Name of the Cluster to Join

Deprecated. Use this parameter to specify the name of an existing cluster to join.

\{-allow-mixed-version-join [true]\} - Allow a Node at a Different Version to Join Cluster

This parameter allows nodes with different, but compatible versions of Data ONTAP to join the cluster. A Data ONTAP best practice is to join nodes to the cluster that are of the same Data ONTAP version as the nodes in the cluster, but that may not always be possible.

\{-node-name <text>\} - Name to Use for the Node in the Cluster

This parameter specifies the name that the node will have when we join it to the cluster.

Examples

The following example joins the local node to a cluster. The IP address 192.0.2.66 is the address of a cluster interface of a node that already belongs to the cluster.

node::> cluster join -clusteripaddr 192.0.2.66

cluster modify

Modify cluster node membership attributes

Availability: This command is available to cluster administrators at the advanced privilege level.

Description

The \cluster modify\ command modifies the cluster attributes of a node, including its eligibility to participate in the cluster. At the advanced privilege level, you can use the command to specify whether a node holds epsilon. Epsilon is an extra fractional vote that enables quorum to form using slightly weaker requirements. For example, two out of four eligible nodes are sufficient to form quorum if one of those two nodes holds epsilon.

Parameters

\{-node {<nodename>|local}\} - Node

Use this parameter to specify the name of the node to modify. If you do not specify a node, the command runs on the local node.

\{-epsilon [true|false]\} - Epsilon

Use this parameter with the value \text{true}\ to specify that the node holds Epsilon in the cluster. Use this parameter with the value \text{false}\ to specify that the node does not hold Epsilon in the cluster. In a cluster, only one node can be designated as Epsilon at any given time. You can designate a node as Epsilon to add weight to its voting in a cluster with an even number of nodes.
[-eligibility {true|false}] - Eligibility

Use this parameter with the value true to specify that the node is eligible to participate in the cluster. Use this parameter with the value false to specify that the node is not eligible to participate in the cluster.

If you modify a node as ineligible to participate in the cluster, the command prompts you for confirmation before it runs.

[-skip-quorum-check-before-eligible {true}] - Skip Quorum Check Before Setting Node Eligible

If this parameter is specified, quorum checks will be skipped prior to setting a node eligible. When setting a node to eligible, the operation will continue even if there is a possible data outage due to a quorum issue.

[-skip-quorum-check-before-ineligible {true}] - Skip Quorum Check Before Setting Node Ineligible

If this parameter is specified, quorum checks will be skipped prior to setting a node ineligible. When setting a node to ineligible, the operation will continue even if there is a possible data outage due to a quorum issue.

Examples

This example modifies a node to make it eligible to participate in the cluster.

cluster1::*> cluster modify -node node3 -eligibility true

The following example removes epsilon from the node named node0 and adds it to the node named node1:

cluster1::*> cluster modify -node node0 -epsilon false
cluster1::*> cluster modify -node node1 -epsilon true

cluster ping-cluster

Ping remote cluster interfaces and perform RPC server check

Availability: This command is available to cluster administrators at the advanced privilege level.

Description

The cluster ping-cluster command probes network connectivity to remote cluster interfaces, and performs an RPC server check.

Parameters

-node <nodename> - Node

Use this parameter to send the ping from the node you specify.

[-use-sitelist {true|false}] - Use Sitelist for Cluster Interfaces

Use this parameter with the value true to specify that the command use the sitelist to determine any incomplete cluster IP information. Use this parameter with the value false to specify that the command not use the sitelist.

[-skip-rpccheck {true|false}] - Skip RPC Server Check

Use this parameter with the value true to specify that the command not perform the rpcinfo check of remote hosts. Use this parameter with the value false to specify that the command perform the rpcinfo check. The rpcinfo check checks the status of the RPC servers on the remote hosts. By default, the rpcinfo check runs on the program number of the portmapper. Use the -rpc-prognum parameter to override this default.

[-rpc-prognum <integer>] - RPC Server to Check

Use this parameter to override default behavior and run the rpcinfo check on the program number you specify. By default, the rpcinfo check runs on the program number of the portmapper.
Examples
The following example shows typical output for this command.

```
cluster1::*> cluster ping-cluster -node node1
Host is node1
Getting addresses from network interface table...
Local = 10.254.231.102  10.254.91.42
Remote = 10.254.42.25    10.254.16.228
Ping status:
....
Basic connectivity succeeds on 4 path(s)
Basic connectivity fails on 0 path(s)
................
Detected 1500 byte MTU on 4 path(s):
Local 10.254.231.102 to Remote 10.254.16.228
Local 10.254.231.102 to Remote 10.254.42.25
Local 10.254.91.42 to Remote 10.254.16.228
Local 10.254.91.42 to Remote 10.254.42.25
Larger than PMTU communication succeeds on 4 path(s)
RPC status:
2 paths up, 0 paths down (tcp check)
2 paths up, 0 paths down (udp check)
```

cluster remove-node

Remove a node from the cluster

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

**Description**
The `cluster remove-node` command removes a node from a cluster.

Before you can remove a node from a cluster, you must shut down all of the node's shared resources, such as virtual interfaces to clients. If any of a node's shared resources are still active, the command fails. The failure message will display which active resources must be shut down before the node can be removed from the cluster.

**Parameters**

- `-node <nodename>` - Node to Unjoin
  Use this parameter to specify the name of the node to remove from the cluster.

- `-cluster-ip <IP Address>` - IP Address of a Cluster Interface of Node to Unjoin
  Use this parameter to specify the cluster IP of the node to remove from the cluster.

- `[-skip-quorum-check-before-unjoin [true]]` - Skip Quorum Check before Unjoin
  If this parameter is specified, quorum checks will be skipped prior to the remove-node command. The operation will continue even if there is a possible data outage due to a quorum issue.

- `[-skip-last-low-version-node-check [true]]` - Skip the Check That Prevents Unjoining the Last Low Versioned Node
  This parameter allows the node with lowest version of Data ONTAP to be removed from the cluster.

Examples
The following example shows how to remove the node named `node4` from the cluster.

```
cluster1::*> cluster remove-node -node node4
```

The following example forcibly removes the node from the cluster:
cluster setup

Setup wizard

Availability: This command is available to cluster administrators at the admin privilege level.

Description

Note: Use of this command to join a node to an existing cluster is deprecated and might be removed in a future release of Data ONTAP. From a node in the cluster use the system node show-discovered command and then use the cluster add-node command.

The cluster setup command runs the cluster setup wizard, which can be used to either create a cluster or join a node to an existing cluster. When you run the cluster setup wizard, enter the appropriate information at the prompts. You will be asked to provide the following information to create a cluster:

- Node management interface port, IP address, netmask, default gateway
- Cluster name
- Cluster base license key
  Note: This parameter has been deprecated. It may be removed from a future release of Data ONTAP.
- Feature license keys
- Cluster administrator’s password
- Cluster management interface port, IP address, netmask, default gateway
- DNS domain names
- Name server IP addresses
- Location

You will be asked to provide the following information to join a cluster:

- Node management interface port, IP address, netmask, default gateway
- Cluster IP address

The cluster management interface is used for managing the cluster. It provides one IP address to manage the cluster and will fail over to another node, if necessary. This is the preferred IP address for managing the cluster, but you can also manage the cluster by logging in to the node management IP address of a node in the cluster. Since the cluster management interface must be able to fail over, the port role for the interface must be "data" and typically the best choice for an IP address is one on the data network. The node management interface will not fail over, so an IP address on the management network and a port with the role "node management" is the best choice. Alternatively, you can assign an IP address on the data network to the cluster management interface - if that is better in your network topology - but the port must be a data port. The two examples below illustrate the cluster create and cluster join operations, respectively.

Examples

The following example shows the create option of cluster setup.
Welcome to the cluster setup wizard.

You can enter the following commands at any time:
"help" or "?" - if you want to have a question clarified,
"back" - if you want to change previously answered questions, and
"exit" or "quit" - if you want to quit the cluster setup wizard.
Any changes you made before quitting will be saved.

You can return to cluster setup at any time by typing "cluster setup".
To accept a default or omit a question, do not enter a value.

This system will send event messages and periodic reports to NetApp Technical Support. To disable this feature, enter autosupport modify -support disable within 24 hours.

Enabling AutoSupport can significantly speed problem determination and resolution should a problem occur on your system.
For further information on AutoSupport, see: http://support.netapp.com/autosupport/

Type yes to confirm and continue {yes}: yes

Enter the node management interface port [e0c]:
Enter the node management interface IP address: 192.0.2.66
Enter the node management interface netmask: 255.255.255.192
Enter the node management interface default gateway: 192.0.2.1
The node management interface has been modified to use port e0c with IP address 192.0.2.66.
Use your web browser to complete cluster setup by accessing https://192.0.2.66

Otherwise, press Enter to complete cluster setup using the command line interface:

Do you want to create a new cluster or join an existing cluster? {create, join}: create

Do you intend for this node to be used as a single node cluster? {yes, no} [no]:

Existing cluster interface configuration found:

<table>
<thead>
<tr>
<th>Port</th>
<th>MTU</th>
<th>IP</th>
<th>Netmask</th>
</tr>
</thead>
<tbody>
<tr>
<td>e0a</td>
<td>9000</td>
<td>169.254.21.189</td>
<td>255.255.0.0</td>
</tr>
<tr>
<td>e0b</td>
<td>9000</td>
<td>169.254.29.73</td>
<td>255.255.0.0</td>
</tr>
</tbody>
</table>

Do you want to use this configuration? {yes, no} [yes]:

Enter the cluster administrator's (username "admin") password:
Retype the password:

Step 1 of 5: Create a Cluster
You can type "back", "exit", or "help" at any question.

Enter the cluster name: cluster1
Creating cluster1
Starting cluster support services.
Cluster cluster1 has been created.

Step 2 of 5: Add Feature License Keys
You can type "back", "exit", or "help" at any question.

Enter an additional license key []:

Step 3 of 5: Set Up a Vserver for Cluster Administration
You can type "back", "exit", or "help" at any question.
Enter the cluster management interface port [e0d]:
Enter the cluster management interface IP address: 192.0.2.60
Enter the cluster management interface netmask: 255.255.255.192
Enter the cluster management interface default gateway [192.0.2.1]:

A cluster management interface on port e0d with IP address 192.0.2.60 has been created. You can use this address to connect to and manage the cluster.

Enter the DNS domain names: data.example.com
Enter the name server IP addresses: 192.0.2.147
DNS lookup for the admin Vserver will use the data.example.com domain.

Step 4 of 5: Configure Storage Failover (SFO)
You can type "back", "exit", or "help" at any question.

SFO is licensed.
SFO will be enabled when the partner joins the cluster.

Step 5 of 5: Set Up the Node
You can type "back", "exit", or "help" at any question.

Where is the controller located []: Sunnyvale

Cluster "cluster1" has been created.

To complete cluster setup, you must join each additional node to the cluster by running "system node show-discovered" and "cluster add-node" from a node in the cluster.

To complete system configuration, you can use either OnCommand System Manager or the Data ONTAP command-line interface.

To access OnCommand System Manager, point your web browser to the cluster management IP address (https://192.0.2.60).

To access the command-line interface, connect to the cluster management IP address (for example, ssh admin@192.0.2.60).

cluster1::>

An example of using cluster setup to join a cluster is shown below.

node::> cluster setup

Welcome to the cluster setup wizard.

You can enter the following commands at any time:
"help" or "?" - if you want to have a question clarified,
"back" - if you want to change previously answered questions, and
"exit" or "quit" - if you want to quit the cluster setup wizard.
Any changes you made before quitting will be saved.

You can return to cluster setup at any time by typing "cluster setup".
To accept a default or omit a question, do not enter a value.

This system will send event messages and periodic reports to NetApp Technical Support. To disable this feature, enter autosupport modify -support disable within 24 hours.

Enabling AutoSupport can significantly speed problem determination and resolution should a problem occur on your system.
For further information on AutoSupport, see:
http://support.netapp.com/autosupport/

Type yes to confirm and continue {yes}: yes
Enter the node management interface port [e0c]:
Enter the node management interface IP address: 192.0.2.67
Enter the node management interface netmask: 255.255.255.192
Enter the node management interface default gateway: 192.0.2.1
A node management interface on port e0c with IP address 192.0.2.67 has been created.

Use your web browser to complete cluster setup by accessing https://192.0.2.67
Otherwise, press Enter to complete cluster setup using the command line interface:

Do you want to create a new cluster or join an existing cluster? {create, join}:
join

Existing cluster interface configuration found:

<table>
<thead>
<tr>
<th>Port</th>
<th>MTU</th>
<th>IP</th>
<th>Netmask</th>
</tr>
</thead>
<tbody>
<tr>
<td>e0a</td>
<td>9000</td>
<td>169.254.31.170</td>
<td>255.255.0.0</td>
</tr>
<tr>
<td>e0b</td>
<td>9000</td>
<td>169.254.115.61</td>
<td>255.255.0.0</td>
</tr>
</tbody>
</table>

Do you want to use this configuration? {yes, no} [yes]:

Step 1 of 3: Join an Existing Cluster
You can type "back", "exit", or "help" at any question.

Enter the IP address of an interface on the private cluster network from the cluster you want to join: 169.254.115.8
Joining cluster at address 169.254.115.8
This node has joined the cluster cluster1.

Step 2 of 3: Configure Storage Failover (SFO)
You can type "back", "exit", or "help" at any question.

SFO is licensed.
SFO will be enabled when the partner joins the cluster.

Step 3 of 3: Set Up the Node
You can type "back", "exit", or "help" at any question.

This node has been joined to cluster "cluster1".

To complete cluster setup, you must join each additional node to the cluster by running "system node show-discovered" and "cluster add-node" from a node in the cluster.
To complete system configuration, you can use either OnCommand System Manager or the Data ONTAP command-line interface.
To access OnCommand System Manager, point your web browser to the cluster management IP address (https://192.0.2.60).
To access the command-line interface, connect to the cluster management IP address (for example, ssh admin@192.0.2.60).

cluster show

Display cluster node members

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**
The `cluster show` command displays information about the nodes in a cluster.

**Parameters**

<table>
<thead>
<tr>
<th><code>-fields &lt;fieldname&gt;, ...</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>If you specify the <code>-fields &lt;fieldname&gt;, ...</code> parameter, the command output also includes the specified field or fields. You can use <code>-fields ?</code> to display the fields to specify.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><code>-instance</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>If you specify the <code>-instance</code> parameter, the command displays detailed information about all fields.</td>
</tr>
</tbody>
</table>

| `-node {<nodename>|local}` |
|-----------------------------|
| Node |
| Selects the nodes that match this parameter value. |

<table>
<thead>
<tr>
<th><code>-node-uuid &lt;UUID&gt;</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>UUID (privilege: advanced)</td>
</tr>
<tr>
<td>Selects the nodes that match this parameter value.</td>
</tr>
</tbody>
</table>

| `-epsilon {true|false}` |
|------------------------|
| Epsilon (privilege: advanced) |
| Selects the nodes that match this parameter value. In a cluster, only one node can be designated as Epsilon at any given time. You can designate a node as Epsilon to add weight to its voting in a cluster with an even number of nodes. |

| `-eligibility {true|false}` |
|-----------------------------|
| Eligibility |
| Selects the nodes that match this parameter value (true means eligible to participate in the cluster). |

| `-health {true|false}` |
|------------------------|
| Health |
| Selects the nodes that match this parameter value (true means online). |

**Examples**
The following example displays information about all nodes in the cluster:

```
cluster1::> cluster show

Node                  Health  Eligibility
--------------------- ------- ------------
node0                 true    true
node1                 true    true
node2                 true    true
node3                 true    true
```

The following example displays information about the node named node1:

```
cluster1::> cluster show -node node1

Node: node1
Eligibility: true
Health: true
```
cluster contact-info commands

Manage contact information for the cluster.

cluster contact-info modify

Modify contact information for the cluster

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The cluster contact-info modify command modifies contact information for the cluster administrators. If any values contain spaces, you must enclose those values in quotes.

Use the cluster contact-info show command to display contact information for the cluster administrators.

Parameters

[-primary-name <text>] - Name of Primary Contact
Use this parameter to specify the name of the primary contact.

[-primary-phone <text>] - Phone Number of Primary Contact
Use this parameter to specify the phone number of the primary contact.

[-primary-alt-phone <text>] - Alternate Phone Number of Primary Contact
Use this parameter to specify the alternate phone number of the primary contact.

[-primary-email <text>] - Email Address or User ID of Primary Contact
Use this parameter to specify the email address of the primary contact.

[-secondary-name <text>] - Name of Secondary Contact
Use this parameter to specify the name of the secondary contact.

[-secondary-phone <text>] - Phone Number of Secondary Contact
Use this parameter to specify the phone number of the secondary contact.

[-secondary-alt-phone <text>] - Alternate Phone Number of Secondary Contact
Use this parameter to specify the alternate phone number of the secondary contact.

[-secondary-email <text>] - Email Address or User ID of Secondary Contact
Use this parameter to specify the email address of the secondary contact.

[-business-name <text>] - Business Name
Use this parameter to specify the name of the business responsible for this cluster.

[-address <text>] - Business Address
Use this parameter to specify the street address of the business responsible for this cluster.

[-city <text>] - City Where Business Resides
Use this parameter to specify the name of the city in which the business is located.

[-state <text>] - State Where Business Resides
Use this parameter to specify the name of the state or province in which the business is located.

Use this parameter to specify the 2-character country code of the country in which the business is located.
[-zip-code <text>] - Postal Code Where Business Resides
Use this parameter to specify the postal or ZIP code area in which the business is located.

**Examples**
The following example changes the name and phone numbers of the secondary contact person for the cluster.

```
cluster1::> cluster contact-info modify -secondary-name "John Doe" -secondary-phone 123.555.0156 -secondary-alt-phone 123.555.0178
```

The following example changes the mailing address of the business responsible for the cluster.

```
cluster1::> cluster contact-info modify -address "123 Example Avenue" -city Exampleville -state "New Example" -zip-code 99999 -country US
```

**Related references**

**cluster contact-info show**

Display contact information for the cluster.

**Availability:** This command is available to `cluster` administrators at the `admin` privilege level.

**Description**
The `cluster contact-info show` command displays contact information for the cluster administrators.

**Examples**
The following example shows example output for this command.

```
cluster1::> cluster contact-info show
                    Name of Primary Contact : Richard Roe
          Phone Number of Primary Contact : 123.555.0123
 Alternate Phone Number of Primary Contact : 123.555.0145
      Email Address or User Id of Primary Contact : roe@example.com
                    Name of Secondary Contact : John Doe
          Phone Number of Secondary Contact : 123.555.0167
 Alternate Phone Number of Secondary Contact : 123.555.0189
      Email Address or User Id of Secondary Contact : doe@example.com
                    Business Name : Example Dot Com
                      Business Address : 123 Example Avenue
                 City Where Business Resides : Exampleville
               State Where Business Resides : New Example
            2-Character Country Code : US
     Postal Code Where Business Resides : 99999
```

**cluster date commands**

Manage cluster's date and time setting

**cluster date modify**

Modify the current date and time for the nodes in the cluster.

**Availability:** This command is available to `cluster` administrators at the `admin` privilege level.
Description
The cluster date modify command sets the time zone, date, and time on every node in the cluster.

Parameters
[-timezone <Area/Location Timezone>] - Time Zone
This parameter sets the timezone, specified in the Olson format.

[-date {MM/DD/YYYY HH:MM:SS [+|-]hh:mm}] - Date and Time
This parameter sets the date and time, in the format MM/DD/YYYY HH:MM:SS.

This parameter sets the date and time information, in the format [[[[cc]yy]mm]dd]hhmm[.ss]]. The argument for setting the date and time is interpreted as follows:

- cc First 2 digits of the year (e.g., 20 for 2011).
- yy Last 2 digits of year (e.g., 10 for 2010).
- mm Numeric month, a number from 01 to 12.
- dd Day, a number from 01 to 31.
- hh Hour, a number from 00 to 23.
- mm Minute, a number from 00 to 59.
- ss Second, a number from 00 to 59.

If the first two digits of the year are omitted, and the last two digits are greater than 68, a date in the 1900s is used. Otherwise, a date in the 2000s is used. If all four digits of the year are omitted, the default is the current year. If the month or day is omitted, the default is the current month or day, respectively. If the seconds are omitted, the default is set to 00. The system automatically handles the time changes for Daylight Saving and Standard time, and for leap seconds and years.

[-utcdateandtime | -u <[[[[cc]yy]mm]dd]hhmm[.ss]>]] - UTC Date and Time
This parameter sets the date and time information in Coordinated Universal Time (UTC), in the format [[[cc]yy]mm]dd]hhmm[.ss]. -u is an alias for -utcdateandtime. The argument for setting the date and time is interpreted as follows:

- cc First 2 digits of the year (e.g., 20 for 2011).
- yy Last 2 digits of year (e.g., 10 for 2010).
- mm Numeric month, a number from 01 to 12.
- dd Day, a number from 01 to 31.
- hh Hour, a number from 00 to 23.
- mm Minute, a number from 00 to 59.
- ss Second, a number from 00 to 59.

If the first two digits of the year are omitted, and the last two digits are greater than 68, a date in the 1900s is used. Otherwise, a date in the 2000s is used. If all four digits of the year are omitted, the default is the current year. If the month or day is omitted, the default is the current month or day, respectively. If the seconds are omitted, the default is set to 00. Time changes for Daylight Saving and Standard time, and for leap seconds and years, are handled automatically.
Examples
The following example sets the date and time to January 1 2011, at 1:00 a.m.:

```bash
cluster1::> cluster date modify -date "01/01/2011 01:00:00"
```

The following example sets the date and time in the UTC format to May 22, 2011, at 09:25:00 a.m.:

```bash
cluster1::> cluster date modify -u 201105220925.00.
```

**cluster date show**

Display the current date and time for the nodes in the cluster

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**
The `cluster date show` command displays the time zone, date, and time settings for one or more nodes in the cluster. By default, the command displays date and time settings for all nodes in the cluster.

**Parameters**

```bash
[-fields <fieldname>, ...]  
If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

[-utc]  
Displays date and time information in Coordinated Universal Time (UTC).

[-utcdate]  
Displays date and time information in UTC.

[-instance]  
If you specify the `-instance` parameter, the command displays detailed information about all fields.

[-node {<nodename>|local}] - Node  
Selects the nodes that match this parameter value.

[-timezone <Area/Location Timezone>] - Time Zone  
Selects the nodes that match this parameter value (specified in the Olson format).

[-date {MM/DD/YYYY HH:MM:SS [(+|-)hh:mm]}] - Date and Time  
Selects the nodes that match this parameter value.

[-utc-date <MM/DD/YYYY HH:MM:SS>] - UTC Date and Time  
Selects the nodes that match this parameter value.

Selects the nodes that match this parameter value (interpreted as follows):

+ cc First 2 digits of the year (e.g., 20 for 2011).
+ yy Last 2 digits of year (e.g., 11 for 2011).
+ mm Numeric month, a number from 01 to 12.
+ dd Day, a number from 01 to 31.
+ hh Hour, a number from 00 to 23.
- mm Minute, a number from 00 to 59.
- ss Second, a number from 00 to 59.

-u is used as an alias for -utcdatetimengetime. Selects the nodes that match this parameter value (interpreted as follows):
- cc First 2 digits of the year (e.g., 20 for 2011).
- yy Last 2 digits of year (e.g., 11 for 2011).
- mm Numeric month, a number from 01 to 12.
- dd Day, a number from 01 to 31.
- hh Hour, a number from 00 to 23.
- mm Minute, a number from 00 to 59.
- ss Second, a number from 00 to 59.

Examples

The following example displays the date and time settings for all nodes in the cluster:

```
cluster1::> cluster date show
Node      Date                Timezone
--------- ------------------- -----------------
node0     10/06/2011 09:35:15 America/New_York
node1     10/06/2011 09:35:15 America/New_York
node2     10/06/2011 09:35:15 America/New_York
node3     10/06/2011 09:35:15 America/New_York
4 entries were displayed.
```

Manage the timezone zoneinfo files.

The zoneinfo directory

Manage the timezone zoneinfo files.

cluster date zoneinfo load-from-uri

Load timezone zoneinfo data

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The `cluster date zoneinfo load-from-uri` command loads a new set of timezone zoneinfo data to replace the version installed in the cluster. Releases of Data ONTAP software contain the timezone data that is current at the time of release. If a change is made to the timezone between Data ONTAP releases, then an update can be made to the release data. For instance, if a change is made to when daylight saving time is observed for a country then an update to cluster zoneinfo data may be required.

Only zoneinfo files provided by NetApp for use in Data ONTAP should be used with this command.

To update the zoneinfo database do the following:
- Download the required zoneinfo file from the NetApp support website.
- Place the file on a local web server accessible without password from the cluster.
- Execute the `cluster date zoneinfo load-from-uri` command, passing the Universal Resource Identifier (URI) of the file as parameter.
Note: The command need only be executed once for the cluster. The data will be distributed to each node of the cluster.

Parameters
- uri (ftp|http)://(hostname|IPv4 Address| '['IPv6 Address']')... - URI of Timezone Zoneinfo

Data
URI of the new zoneinfo file.

Examples
The following example loads a new version of the timezone zoneinfo database to the cluster:

```
cluster1::> cluster date zoneinfo load-from-uri http://www.example.com/ontap_zoneinfo.zip
```

Related references
cluster date zoneinfo show on page 32

cluster date zoneinfo show
Display cluster timezone zoneinfo information

Availability: This command is available to cluster administrators at the admin privilege level.

Description
Display information about the current timezone zoneinfo data.

Examples
The following example shows the zoneinfo information for a cluster:

```
cluster1::> cluster date zoneinfo show
Cluster Zoneinfo Version: 2016f
```

cluster ha commands
Manage high-availability configuration

cluster ha modify
Modify high-availability configuration of cluster management services

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The cluster ha modify command enables or disables cluster high availability in a two-node cluster. Enable high availability when performing some procedures, such as replacing hardware.

Note: This command is required to enable high availability if the cluster only has two nodes. Do not run this command in a cluster that has three or more nodes.

Note: Cluster high availability for two-node clusters differs from the storage failover technology used between two nodes for storage high availability.
Parameters

[-configured (true|false)] - HA Configured

Use this parameter with the value true to enable high availability mode in the cluster. Use this parameter with the value false to disable high availability mode in the cluster.

Examples

The following example enables cluster high availability in a cluster.

```
cluster1::> cluster ha modify -configured true
```

cluster ha show

Show high-availability configuration status for the cluster

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The `cluster ha show` command displays the high-availability status of the cluster. Cluster high-availability mode applies only to two-node clusters.

Examples

The following example displays the high-availability status for a two-node cluster:

```
cluster1::> cluster ha show
High Availability Configured: true
```

cluster identity commands

Manage the cluster's attributes, including name and serial number

cluster identity modify

Modify the cluster's attributes

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The `cluster identity modify` command changes a cluster's identity information.

Parameters

[-name <Cluster name>] - Cluster Name

Use this parameter to specify a new name for the cluster.

- The name must contain only the following characters: A-Z, a-z, 0-9, "." or ":".
- The first character must be one of the following characters: A-Z or a-z.
- The last character must be one of the following characters: A-Z, a-z or 0-9.
- The maximum supported length is 44 characters.
- The system reserves the following names: "all", "cluster", "local" and "localhost".
[-location <text>] - Cluster Location

Use this parameter to specify the physical location of the cluster. For example, "Lab 5".

[-contact <text>] - Cluster Contact

Use this parameter to specify contact information for the cluster, such as a name or e-mail address.

**Examples**

The following example renames the current cluster to cluster2:

```
cluster1::> cluster identity modify -name cluster2
```

**cluster identity show**

Display the cluster's attributes including Name, Serial Number, Cluster UUID, Location and Contact

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**

The `cluster identity show` command displays the identity information of the cluster.

**Examples**

The following example displays the cluster's UUID, name, serial number, location and contact information:

```
cluster1::> cluster identity show
    Cluster UUID: 1cd8a442-86d1-11e0-ae1c-123478563412
    Cluster Name: cluster1
    Cluster Serial Number: 1-80-123456
    Cluster Location: Lab2
    Cluster Contact: jsmith@example.com

cluster1::>
```

The following example displays the cluster's UUID, name, serial number, location, contact information, and RDB UUID:

```
cluster1::> set -privilege diagnostic
Warning: These diagnostic commands are for use by NetApp personnel only.
Do you want to continue? {y|n}: y
cluster1::*> cluster identity show
    Cluster UUID: 1cd8a442-86d1-11e0-ae1c-123478563412
    Cluster Name: cluster1
    Cluster Serial Number: 1-80-123456
    Cluster Location: Lab2
    Cluster Contact: jsmith@example.com
    RDB UUID: 1cd8f3bf-86d1-11e0-ae1c-123478563412

cluster1::*>
```

**cluster image commands**

Manage cluster images for automated nondisruptive update
**cluster image cancel-update**

Cancel an update

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**
The `cluster image cancel-update` command is used to cancel an update that is in either paused-by-user or paused-by-error state. The update cannot be canceled if it is not in a paused state.

**Examples**
The following example displays a cancel-update operation:

```
cluster1::> cluster image cancel-update
Warning: The cancel operation can result in a mixed version cluster and/or mixed version HA pair. The cancel operation can take several minutes to complete.
Do you want to proceed with the cancel operation? {y|n}: y
Info: Canceling update. It may take a few minutes to finish canceling the update
```

**cluster image pause-update**

Pause an update

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**
The `cluster image pause-update` command is used to pause a currently running update. The update pauses at the next predefined pause point (for example, after validation, download to the boot device, takeover completion, or giveback completion) which might take some time to reach. When the update reaches the pause point, it transitions into the pause-by-user state.

**Examples**
The following example displays pause-update operation:

```
cluster1::> cluster image pause-update
Info: Pausing update. It may take a few minutes to finish pausing the update
```

**cluster image resume-update**

Resume an update

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**
The `cluster image resume-update` command is used to resume an update that is currently paused in paused-by-user or paused-by-error state. If the update is not paused then an error is returned.
Parameters

[-ignore-post-update-checks-failures {true|false}] - Ignore Post-update-checks Phase Failures

(privilege: advanced)

Specifies whether the post update checks phase warnings and/or errors should be ignored. The default value is false.

Examples

The following example shows an resume-update operation:

```text
cluster1::> cluster image resume-update
Info: Resuming update...
```

cluster image show

Display currently running image information

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The `cluster image show` command displays information about the version of Data ONTAP that is running on each node and the date/time when it was installed. By default, the command displays the following information:

- Node name
- Current version
- Installation date and time

Parameters

`{ [ -fields <fieldname>, ... ] }`

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

`{ [-instance ] ]`

If you specify the `-instance` parameter, the command displays detailed information about all fields.

`[-node <nodename> | local] - Node`

Displays information about the specified node.

`[-version <text>] - Current Version`

Displays information about the nodes running the specified version.

`[-date <MM/DD/YYYY HH:MM:SS>] - Date Installed`

Displays information about the nodes with the specified installation date.

Examples

The following example displays information about currently running images on all nodes of the cluster:

```text
cluster1::> cluster image show
+----------+----------------+------------------+
| Node     | Current Version | Installation Date |
+----------+----------------+------------------+
|          |                |                  |
+----------+----------------+------------------+
### cluster image show-update-history

Display the update history

**Availability:** This command is available to cluster administrators at the `admin` privilege level.

**Description**
The `cluster image show-update-history` command displays the update history for each node. By default, the command displays the following information:

- Status
- Package version
- Start time
- Completion time
- Component ID
- Previous version
- Updated version

**Parameters**

```
[-fields <fieldname>, ...]
```

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

```
[-instance ]
```

If you specify the `-instance` parameter, the command displays detailed information about all fields.

```
[-component-id {<nodename>|local}] - Component ID
```

Displays updates for the specified component.

```
[-start-time <MM/DD/YYYY HH:MM:SS>] - Start Time
```

Displays updates with the specified start time.

```
[-package-version <text>] - Package Version
```

Displays updates for the specified package version.

```
[-status {successful|canceled|back-out}] - Status
```

Displays updates that completed with the specified status.

```
[-completion-time <MM/DD/YYYY HH:MM:SS>] - Completion Time
```

Displays updates with the specified completion time.

```
[-previous-version <text>] - Previous Version
```

Displays updates with the specified previous version.

```
[-updated-version <text>] - Updated Version
```

Displays updates with the specified updated version.

cluster image show-update-log
Display the update transaction log

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
The `cluster image show-update-log` command displays detailed information about the currently running, or previously run nondisruptive updates. By default, the command displays the following information:

- Phase
- Transaction
- Transaction ID
- Component ID
- Time stamp
- Status

Parameters

```
[-fields <fieldname>, ...]  
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

[-instance]]
If you specify the -instance parameter, the command displays detailed information about all fields.

[-trans-id <integer>] - Transaction ID
Displays information for the step associated with the specified transaction ID.

[-component-id (<nodename> | local)] - Component ID
Displays information for steps associated with the specified component.
```
[--phase {validation|prereq-updates|ontap-updates|package-management|default-phase|post-update-checks}] - Transaction Phase

Displays information for steps associated with the specified update phase.

Displays information for steps associated with the specified transaction.

[--timestamp <MM/DD/YYYY HH:MM:SS>] - Timestamp

Displays information for steps associated with the specified timestamp.

[--status {waiting|started|completed|paused-on-error|paused-by-user|pause-pending|cancel-pending|canceled|failed}] - Status

Displays information for steps matching the specified status.

**Examples**

The following example displays information about automated nondisruptive update events:

```

```
cluster image show-update-log-detail

Display detailed information about nondisruptive update events

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
The cluster image show-update-log-detail command displays detailed information about the currently running and previously run nondisruptive update events. By default, the command displays the following information:

• Node
• Transaction ID
• Time stamp
• Destination node
• Task phase
• Task name
• Task status
• Message

Parameters

{[-fields <fieldname>, ...]
    If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use ‘-fields ?’ to display the fields to specify.
}[[-instance]]
    If you specify the -instance parameter, the command displays detailed information about all fields.
[-node (<nodename> | local)] - Node
    Displays information only for the specified node.
[-task-id <integer>] - Task Id
    Displays information only for the specified task ID.
[-posted-time <MM/DD/YYYY HH:MM:SS>] - Posted Time
    Displays information that occurred at the specified time.
[-msg-seq-no <integer>] - Message Sequence
    Displays information only for the specified message sequence number.
[-current-pid <integer>] - Process ID
    Displays information only for the specified process ID.
[-destination <text>] - Task Target node
    Displays information only for the specified destination node.
[-ndu-phase {validation|prereq-updates|ontap-updates|package-management|default-phase|post-update-checks}] - Update phase
    Displays information only for the specified phase.
[-task-name {initialize|mount-image|restart-hm|get-health|run-scripts|unmount-image|clear-alert|post-restart-hm|cleanup-rd|synch-image|do-download-job|do-failover-job|do-giveback-
job|check-progress|complete-validation|invalid-task|default-task|do-postupdate-checks-task] - Task Name

Displays information only for the specified task name.

[-status {created|ready-to-run|running|completed|failed|pause_req|paused|paused-error|cancel_req|canceled|resume_req|default_status}] - Status Of Task

Displays information only for items with the specified status.

[-message <text>] - Update Log Message

Displays information only for items with the specified message.

[-msg-type <text>] - Type Of Message

Displays information only for items with the specified message type.

[-src-info <text>] - Source Information

Displays information only for items for the specified source.

Examples

The following example displays detailed information automated nondisruptive updates:

```
cluster1::*> cluster image show-update-log-detail

Time     Dest     Task   Task   Task
Node   TID Stamp    Node     Phase  Name   Status Message
------ --- -------- -------- ------ ------ ------ --------------------------
node1  15  3/19/14              MUM      ontap- initia ready- Created Task
        13:52:38          update lize to-run
node1  15  3/19/14              MUM      ontap- initia runnin Updated Task Status
        13:52:38          update lize g
node1  16  3/19/14              node1    ontap- do- ready- Created Task
        13:52:38          update downlo to-run
node1  16  3/19/14              node1    ontap- do- runnin Updated Task Status
        13:52:38          update downlo g
node2  17  3/19/14              node2    ontap- do- ready- Created Task
        13:52:38          update downlo to-run
node2  17  3/19/14              node2    ontap- do- runnin Updated Task Status
        13:52:38          update downlo g

6 entries were displayed.
```

**cluster image show-update-progress**

Display the update progress

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**

The *cluster image show-update-progress* command displays information about the current state of an update. By default, the command displays the following information:

- Update phase
- Status
- Estimated Duration
- Elapsed Duration
Parameters
{[-fields <fieldname>, ...]

If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use ‘-fields ?’ to display the fields to specify.

[-instance ]

If you specify the -instance parameter, the command displays detailed information about all fields.

[-ndu-phase {validation|prereq-updates|ontap-updates|package-management|default-phase|post-update-checks}] - Update Phase
Displays information about the specified update phase.

[-phase-status {in-progress|waiting|paused-by-user|paused-on-error|completed|canceled|failed|pause-pending|cancel-pending}] - Phase Status
Displays information about progress matching the specified phase status.

[-phase-duration <text>] - Phase Duration
Displays information about progress matching the specified phase duration.

[-phase-comments <text>] - Phase Comments
Displays information about progress matching the specified phase comments.

[-elapsed-duration {<seconds> | [<d> days] <hh>:<mm>[::<ss>]}] - Elapsed duration of the phase
Displays information about progress matching the specified elapsed duration.

[-estimated-duration {<seconds> | [<d> days] <hh>:<mm>[::<ss>]}] - Estimated duration of the phase
Displays information about progress matching the specified estimated duration.

[-phase-description <text>] - Phase Description
Displays information about progress matching the specified phase description.

[-subsystem-name <text>] - Subsystem Name
Displays information about progress matching the specified subsystem name.

[-subsystem-status <text>] - Subsystem Status
Displays information about progress matching the specified subsystem status.

[-subsystem-details <text>] - Subsystem Details
Displays information about progress matching the specified subsystem details.

[-subsystem-action <text>] - Subsystem Action
Displays information about progress matching the specified subsystem action.

Examples
The following example shows the automated nondisruptive update of two nodes, nodeA and nodeB. In this case, nodeA’s update is waiting, nodeB’s update is in progress. nodeB’s giveback operation is in progress.

```
cluster1::> cluster image show-update-progress

Update Phase          Status                   Estimated Duration             Elapsed Duration
--------------------- ----------------- --------------- ---------------
Pre-update checks     completed                00:10:00        00:00:02
Data ONTAP updates    in-progress              01:23:00        00:32:07

Details:
Node name            Status            Status Description
--------------------- ----------------- ---------------------------------
nodeA                waiting
```

Commands: Manual Page Reference
The following example shows the automated nondisruptive update of two nodes, nodeA and nodeB. In this case, automated nondisruptive update is paused-on-error in "Data ONTAP updates" phase. nodeA's update is waiting, nodeB's update is failed. "Status Description" show nodeB's error and action.

```
cluster1::> cluster image show-update-progress

Update Phase       Status     Estimated Duration     Elapsed Duration
-------------------- ----------------- --------------- ---------------
Pre-update checks   completed     00:10:00        00:00:02
Data ONTAP updates paused-on-error     00:49:00        00:05:21

Details:
Node name      Status            Status Description
-------------------- ----------------- ----------------------------------
nodeA          waiting
nodeB          failed            Error: Takeover of node "nodeB" is not possible.
                            Action: Use the "storage failover show" command to view the cause of the failure.

2 entries were displayed.

Status: Paused - An error occurred in "Data ONTAP updates" phase. The non-disruptive update cannot continue until the error has been resolved. Resolve all issues, then use the "cluster image resume-update" command to resume the update.
```

The following example shows that the automated nondisruptive update is completed on nodeA and nodeB.

```
cluster1::> cluster image show-update-progress

Update Phase       Status     Estimated Duration     Elapsed Duration
-------------------- ----------------- --------------- ---------------
Data ONTAP updates completed     02:19:00        00:00:03
Post-update checks paused-on-error     00:10:00        00:00:02

Details:
Post-update Check       Status     Error-Action
-------------------- -------------- -------------------------------------
Cluster Quorum          Error      Error: Cluster is not in quorum.
                            Action: Use the (privilege: advanced) "cluster ring show" command to verify all replication unit details.

5 entries were displayed.

Status: Paused - An error occurred in "Post-update checks" phase. The non-disruptive update cannot continue until the error has been resolved. Resolve all issues, then use the "cluster image resume-update" command to resume the update.
```

The following example shows that the automated nondisruptive update is completed on nodeA and nodeB.
The following example shows the automated update of two-node MetroCluster configuration having clusters cluster_A and cluster_B. In this case, cluster_A’s update is waiting and cluster_B’s update is in progress. cluster_B’s switchback operation is in progress.

```
cluster_A::> cluster image show-update-progress
```

**cluster image update**

Manage an update

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**

The `cluster image update` command is used to initiate a Data ONTAP update. The update is preceded by a validation of the cluster to ensure that any issues that might affect the update are identified. There are two types of updates of a cluster. A rolling update updates Data ONTAP one HA pair at a time. This type of update is performed for clusters with fewer than eight nodes or when the `-force-rolling` option is specified for clusters with eight or more nodes. A batch update is used for clusters of eight or more nodes, and performs updates of multiple HA pairs at the same time.

There are predefined points in the update when the update can be paused (either by the user or by an error). These pause points occur after validation, after download to the boot device, after takeover has completed, and after giveback has completed.
Parameters

**-version <text>** - Update Version

Specifies the Data ONTAP version to use to update the cluster.

**-nodes (<nodename> | local), ...** - Node

Specifies the nodes that are to be updated. This parameter is not supported for updates of MetroCluster configurations and for two-stage upgrades.

**-estimate-only [true]** - Estimate Only

Creates a report of the steps that occur during the update without actually doing them.

**-pause-after {none | all}** - Update Pause

Specifies that the update should pause at each predefined pause points (for example, after validation, after download to the boot device, after takeover, and after giveback) during the update.

**-ignore-validation-warning {true | false}** - Ignore Validation

Specifies that the update should proceed even if the validation reports warnings.

**-skip-confirmation {true | false}** - Skip Confirmation

Specifies that a validation that does not detect any error issues should not ask the user to confirm the update but simply proceed with the update.

**-force-rolling [true]** - Force Rolling Update

This option is used for clusters with eight or more nodes to specify that a rolling update (one HA pair at a time) should be done. This parameter is not supported for single-node cluster and two-node MetroCluster.

**-stabilize-minutes <integer>** - Minutes to stabilize

Specifies the number of minutes that the update should wait after a takeover or giveback is completed. This allows time for the clients to recover from the pause in I/O that occurs during takeover and giveback. This parameter is not supported for single-node cluster.

Examples

The following example shows the update operation:

```
cluster1::> cluster image update -version 8.3
It can take several minutes to complete validation...
Pre-update Check                Status       Error-Action
--------------------------------------------
CIFS status                     OK
Cluster health status          OK
Cluster quorum status          OK
Disk status                     OK
High Availability              OK
status                         OK
LIF status                     OK
LIFs on home node              OK
status                         OK
MetroCluster                   OK
configuration status          OK
SnapMirror status              OK
Overall Status                 OK
10 entries were displayed.

Do you want to continue? {y|n}: y
Starting update...
```
**cluster image validate**

Validates the cluster’s update eligibility

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**
The *cluster image validate* command checks for issues within the cluster that might lead to problems during the update.

**Parameters**

```
[-fields <fieldname>, ...]
```

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

```
[-version <text>] - Update Version
```

Specifies the Data ONTAP version to use to validate the cluster.

```
[-rolling [true]] - Rolling Update
```

Specify this optional parameter on a cluster with eight or more nodes to perform a rolling-update check. The default is to perform a batch-update check.

**Note:** This parameter is only supported on a cluster with eight or more nodes, and is not supported for two-node MetroCluster.

```
[-nodes {<nodename>|local}, ...] - Nodes
```

Specifies the nodes that are to be validated. This parameter is not supported for MetroCluster configurations and for two-stage upgrades.

**Examples**
The following example shows the validate operation:

```bash
cluster1:/> cluster image validate -version 8.3
It can take several minutes to complete validation...
Pre-update Check Status Error-Action
---------------------  --------- -------------------------------------------
CIFS status OK
Cluster health status OK
Cluster quorum status OK
Disk status OK
High Availability OK
status
LIF status OK
LIFs on home node OK
MetroCluster configuration status
SnapMirror status OK
Overall Status OK
10 entries were displayed.
```

**cluster image package commands**

Manage the cluster image package repository

**cluster image package delete**

Remove a package from the cluster image package repository

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.
Description
The `cluster image package delete` command deletes the specified version of the package from the package repository. The associated information about the package is also deleted from the update database.

Parameters
- `version <text>` - Version To Be Deleted
  Specifies the package version that is to be deleted.

Examples
The following example deletes the package with version 8.3:

```
cluster1::> cluster image package delete -version 8.3
Package Delete Operation Completed Successfully
```

---

**cluster image package get**

Fetch a package file from a URL into the cluster image package repository

*Availability:* This command is available to `cluster` administrators at the `admin` privilege level.

Description
The `cluster image package get` command fetches a Data ONTAP package file specified by the URL into the cluster. The package is stored in the cluster package repository and the information from the package is stored in the update database.

Parameters
- `url <text>` - Package URL
  Specifies the URL from which to get the package.

Examples
The following example displays how to get a package from a URL:

```
cluster1::> cluster image package get -url http://example.com/image.tgz
```

---

**cluster image package show-repository**

Display information about packages available in the cluster image package repository

*Availability:* This command is available to `cluster` administrators at the `admin` privilege level.

Description
The `cluster image package show-repository` command displays the package versions that are in the cluster package repository. By default, the command displays the following information:

- Package version

Parameters

```
{ [-fields <fieldname>, ...]
```

If you specify the `fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `'-fields ?'` to display the fields to specify.
This parameter specifies that detailed information should be displayed.

If you specify the -instance parameter, the command displays detailed information about all fields.

Displays packages with the specified download version.

Displays packages for the specified component.

Displays packages with the specified component version.

Displays packages with the specified build time.

Examples
The following example displays the packages in the cluster package repository:

```
cluster1::> cluster image package show-repository
Package Version Package Build Time
--------------- ------------------
8.3             9/12/2014 10:27:33
```

### cluster kernel-service commands

Display and manage the cluster kernel services

Commands and methods used to manage the distributed kernel services of the cluster.

### cluster kernel-service show

Display cluster service state in the kernel

**Availability:** This command is available to cluster administrators at the advanced privilege level.

**Description**

The `cluster kernel-service show` command displays the following information from the master node for each node in the cluster:

- Node name
- The quorum status of that node
- The availability status of that node
- The operational status of that node

**Parameters**

```
[-fields <fieldname>, ...]
```

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.
If you specify the \texttt{-instance} parameter, the command displays detailed information about all fields.

\textbf{\texttt{-master-node \{<nodename>|local\}} - Node}

The node in the cluster where the information be being reported from. If this parameter is not specified, the command displays information about all nodes in the cluster.

\textbf{\texttt{-cluster-node \{text\}} - Cluster Node}

The node in the cluster that the information listed is regarding. If this parameter is specified, the command displays information only about the nodes with the specified state value.

\textbf{\texttt{-status-quorum \{out-of-quorum|in-quorum\}} - Quorum Status}

The quorum status of the node specified by \texttt{-cluster-node}. If this parameter is specified, the command displays information only about the nodes with the specified state value.

\textbf{\texttt{-status-avail \{false|true|unknown\}} - Availability Status}

The availability status of the node specified by \texttt{-cluster-node}. If this parameter is specified, the command displays information only about the nodes with the specified state value.

\textbf{\texttt{-status-oper \{unknown|operational|not-operational\}} - Operational Status}

The operational status of the node specified by \texttt{-cluster-node}. If this parameter is specified, the command displays information only about the nodes with the specified state value.

\section*{Examples}

The following example displays information about all nodes in the cluster:

\begin{verbatim}
cluster1::*> cluster kernel-service show
Master            Cluster           Quorum        Availability  Operational
Node              Node              Status        Status        Status
----------------- ----------------- ------------- ------------- --------------
c cluster1-01       c cluster1-01       in-quorum     true          operational
c cluster1-02       in-quorum     true          operational
2 entries were displayed.

cluster1::*> cluster kernel-service show -instance

Master Node: cluster1-01
Cluster Node: cluster1-01
Quorum Status: in-quorum
Availability Status: true
Operational Status: operational

Master Node: cluster1-01
Cluster Node: cluster1-02
Quorum Status: in-quorum
Availability Status: true
Operational Status: operational
2 entries were displayed.
\end{verbatim}

\section*{cluster log-forwarding commands}

Manage the cluster's log forwarding configuration

\subsection*{cluster log-forwarding create}

Create a log forwarding destination

\textbf{Availability}: This command is available to \textit{cluster} administrators at the \textit{admin} privilege level.
Description
The cluster log-forwarding create command creates log forwarding destinations for remote logging.

Parameters
-destination <Remote InetAddress> - Destination Host
  Host name or IPv4 or IPv6 address of the server to forward the logs to.

-[port <integer>] - Destination Port
  The port that the destination server listen on.

-[protocol {udp-unencrypted|tcp-unencrypted|tcp-encrypted}] - Log Forwarding Protocol
  The protocols are used for sending messages to the destination. The protocols can be one of the following values:
  • udp-unencrypted - User Datagram Protocol with no security
  • tcp-unencrypted - Transmission Control Protocol with no security
  • tcp-encrypted - Transmission Control Protocol with Transport Layer Security (TLS)

-[verify-server {true|false}] - Verify Destination Server Identity
  When this parameter is set to true, the identity of the log forwarding destination is verified by validating its certificate. The value can be set to true only when the tcp-encrypted value is selected in the protocol field. When this value is true the remote server might be validated by OCSP. The OCSP validation for cluster logs is controlled with the security config ocsp enable -app audit_log and security config ocsp disable -app audit_log.

-[facility <Syslog Facility>] - Syslog Facility
  The syslog facility to use for the forwarded logs.

-[force [true]] - Skip the Connectivity Test
  Normally, the cluster log-forwarding create command checks that the destination is reachable via an ICMP ping, and fails if it is not reachable. Setting this value to true bypasses the ping check so that the destination can be configured when it is unreachable.

Examples
This example causes audit logs to be forwarded to a server at address 192.168.0.1, port 514 with USER facility.

```
cluster1::> cluster log-forwarding create -destination 192.168.0.1 -port 514 -facility user
```

cluster log-forwarding delete
Delete a log forwarding destination

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The cluster log-forwarding delete command deletes log forwarding destinations for remote logging.

Parameters
-destination <Remote InetAddress> - Destination Host
  Host name or IPv4 or IPv6 address of the server to delete the forwarding entry for.

-port <integer> - Destination Port
  The port that the destination server listen on.
Examples
This example deletes the forwarding of all logs to the server at address 1.1.1.1, port 514.

```
cluster1::> cluster log-forwarding delete -destination 1.1.1.1 -port 514
```

cluster log-forwarding modify
Modify log forwarding destination settings

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The cluster log-forwarding modify command modifies log forwarding destinations for remote logging.

Parameters
- **-destination <Remote InetAddress>** - Destination Host
  The host name or IPv4 or IPv6 address of the server to be modified.
- **-port <integer>** - Destination Port
  The port that the destinations servers listen on.

   - **[-verify-server {true|false}]** - Verify Destination Server Identity
     When this parameter is set to true, the identity of the log forwarding destination is verified by validating its certificate. The value can be set to true only when the tcp-encrypted value is selected in the protocol field. When this value is true the remote server might be validated by OCSP. The OCSP validation for cluster logs is controlled with the security config ocsp enable -app audit_log and security config ocsp disable -app audit_log.

   - **[-facility <Syslog Facility>]** - Syslog Facility
     The syslog facility to use for the forwarded logs.

Examples
This example modifies the facility of audit logs that are forwarded to the destination server at address 192.168.0.1, port 514.

```
cluster1::> cluster log-forwarding modify -destination 192.168.0.1 -port 514 -facility local1
```

cluster log-forwarding show
Display log forwarding destinations

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The cluster log-forwarding show command displays log forwarding information:

- Destination (IPv4/IPv6/hostname)
- Port number
- List of log classes
• Facility

**Parameters**

{ [-fields <fieldname>, ...] }

If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

{ [-instance] }

If you specify the -instance parameter, the command displays detailed information about all fields.

{ [-destination <Remote InetAddress>] - Destination Host }

If this optional parameter is specified, the command displays information about the forwarding destinations with the specified host name, IPv4 or IPv6 address.

{ [-port <integer>] - Destination Port }

If this optional parameter is specified, the command displays information about the forwarding destinations with the specified ports.

{ [-protocol {udp-unencrypted|tcp-unencrypted|tcp-encrypted}] - Log Forwarding Protocol }

If this optional parameter is specified, the command displays information about the forwarding destinations with the specified protocols.

{ [-verify-server {true|false}] - Verify Destination Server Identity }

If this optional parameter is specified, the command displays information about the forwarding destinations with the specified verify-server values.

{ [-facility <Syslog Facility>] - Syslog Facility }

If this optional parameter is specified, the command displays information about the forwarding destinations with the specified facility.

**Examples**

```bash
cluster-1::> cluster log-forwarding show

<table>
<thead>
<tr>
<th>Destination Host</th>
<th>Port</th>
<th>Protocol</th>
<th>Verify</th>
<th>Syslog Facility</th>
</tr>
</thead>
<tbody>
<tr>
<td>192.168.0.1</td>
<td>514</td>
<td>udp-unencrypted</td>
<td>false</td>
<td>user</td>
</tr>
</tbody>
</table>
```

### cluster peer commands

Manage cluster peer relationships

#### cluster peer create

Create a new cluster peer relationship

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**

The `cluster peer create` command establishes a peer relationship between two clusters. Cluster peering enables independent clusters to coordinate and exchange data.

Before creating a new cluster peer relationship, make sure that both clusters are individually healthy and that there are no other peer relationships between the two clusters that might interfere with the new relationship.
You can create a cluster peer relationship using the IPv4 or IPv6 protocol. You may not use both protocols within a single relationship.

Use the `cluster show` and `cluster peer show` commands on each cluster to display health, peering eligibility, and peering information about the two clusters.

**Parameters**

`[-peer-addrs <Remote InetAddress>, ...]` - Remote Intercluster Addresses

Use this parameter to specify the names or IP addresses of the logical interfaces used for intercluster communication. Separate the addresses with commas.

The addresses you provide here are associated with the remote cluster until you modify or delete the relationship, regardless of whether the addresses are valid. Make sure to provide addresses which you know will remain available on the remote cluster. You can use the hostnames of the remote cluster's intercluster addresses, the IP addresses of the remote cluster's intercluster LIFs or both.

`[-username <text>]` - Remote User Name

Use this optional parameter to specify a username that runs a reciprocal `cluster peer create` command on the peered cluster. If you choose not to use the reciprocal creation option, by not supplying a username for reciprocal creation, you must run `cluster peer create` again on the remote cluster to complete the peering relationship.

If you specify the username for the remote cluster, you will be prompted to enter the associated remote password. These credentials are not stored, they are used only during creation to authenticate with the remote cluster and to enable the remote cluster to authorize the peering request. The provided username's profile must have access to the console application in the remote cluster.

Use the `security login role show` and `security login show` commands on each cluster to find user names and their privilege levels.

`[-no-authentication [true]]` - Do Not Use Authentication

Use this optional parameter when omitting the `[-username]` parameter to indicate that you will create an unauthenticated peering relationship.

`[-timeout <integer>]` - Operation Timeout (seconds) (privilege: advanced)

Use this optional parameter to specify a timeout value for peer communications. Specify the value in seconds. The default timeout value is 60 seconds.

`[-address-family {ipv4|ipv6}]` - Address Family of Relationship

Use this optional parameter to specify the address family of the cluster peer relationship. The default is based on existing relationships, existing local intercluster LIFs belonging to a particular address-family, and the addresses supplied to the `cluster peer create` command.

`[-offer-expiration (MM/DD/YYYY HH:MM:SS | {1..7}days | {1..168}hours | PnDTnHnMnS | PnW])` - Passphrase Match Deadline

Specifying `cluster peer create` normally creates an offer to establish authentication with a cluster that is a potential cluster peer to this cluster. Such offers expire unless they are accepted within some definite time. Use this optional parameter to specify the date and time at which this offer should expire, the time after which the offer will no longer be accepted.

`[-rpc-connect-timeout <integer>]` - Timeout for RPC Connect (seconds) (privilege: advanced)

Use this optional parameter to specify a timeout value for the RPC connect during peer communications. Specify the value in seconds. The default timeout value is 10 seconds.

`[-update-ping-timeout <integer>]` - Timeout for Update Pings (seconds) (privilege: advanced)

Use this optional parameter to specify a timeout value for pings while updating remote cluster information. Specify the value in seconds. The default timeout value is 5 seconds. This parameter applies only to cluster peer relationships using the IPv4 protocol.
[--ipspace <IPspace>] - IPspace for the Relationship
Use this optional parameter to specify the IPspace within which the cluster peering relationship is to operate.
The default is to use the 'Default' IPspace.

[--local-name <Cluster name>]- Peer Cluster Local Name
Use this optional parameter to specify a unique local name to identify the remote cluster that is being peered.
The local name must conform to the same rules as a cluster name. The default value is the remote cluster name.

[--generate-passphrase [true]] - Use System-Generated passphrase
Use this optional parameter alone to create cluster peer offer for the unidentified clusters or use it along with --peer-addrs option to automatically generate the passphrase for the cluster peer operation with the peer cluster.

[--initial-allowed-vserver-peers <Vserver Name>, ...] - Vservers allowed for auto peering
Use this optional parameter to specify the list of Vservers for which reciprocal Vserver peering with peer cluster should be enabled. Upon the time of successful peering, Vserver peer permission entries will be created for the peer cluster for the specified list of Vservers.

[--encryption-protocol-proposed {none|tls-psk}] - Encryption Protocol To Be Used In Inter-Cluster Communication
Use this optional parameter to specify how this cluster should use encryption in data connections to the other cluster. Specify 'tls-psk' to specify that TLS should be used with a Pre-Shared Key. Specify 'none' to use no encryption. Where authentication is used, the default is 'tls-psk'. Where authentication is not used, the default is 'none'.

Examples
This example creates a peer relationship between cluster1 and cluster2. This reciprocal create executes the create command on both the local cluster and the remote cluster. The cluster peer create command can use the hostnames of cluster2's intercluster addresses, the IP addresses of cluster2's intercluster LIFs, or both. Note that the admin user's password was typed at the prompt, but was not displayed.

```bash
cluster1::> cluster peer create -peer-addrs cluster2-d2, 10.98.234.246 -username admin
Remote Password:
```

```bash
cluster1::> cluster peer show -instance
```

Peer Cluster Name: cluster2
Remote Intercluster Addresses: cluster2-d2, 10.98.234.246
Availability of the Remote Cluster: Available
Remote Cluster Name: cluster2
Active IP Addresses: 10.98.234.246, 10.98.234.243
Cluster Serial Number: 1-80-123456
Address Family of Relationship: ipv4
Authentication Status Administrative: no-authentication
Authentication Status Operational: absent
Last Update Time: 02/05 21:05:41
IPspace for the Relationship: Default
Encryption for Inter-Cluster Communication: none

This example shows coordinated peer creation. The cluster peer create command was issued locally on each cluster. This does not require you to provide the username and password for the remote cluster. There is a password prompt, but if you are logged in as the admin user, you may simply press enter.

```bash
cluster1::> cluster peer create -peer-addrs cluster2-d2, 10.98.234.246 -no-authentication
Remote Password:
```

```
NOTICE: Addition of the local cluster information to the remote cluster has failed with the following error: not authorized for that command. You may need to repeat this command on the remote cluster.
```

54

Commands: Manual Page Reference
This example shows a reciprocal cluster peer create over IPv6 addresses, that establishes a cluster peer relationship with an IPv6 address family.

This example shows creation of an authenticated peering relationship. It is an example of using the coordinated method to create a cluster peer relationship. The `cluster peer create` command is issued locally on each cluster. Before executing this pair of commands, a passphrase to be used with the commands is chosen and given at the prompts. The passphrase can be any text; it is prompted for twice on each cluster, and all four copies of the passphrase must agree. The passphrase does not echo on the screen. The passphrase must be longer than the minimum length as specified by the `cluster peer policy` on both clusters.
This example creates a peer relationship between cluster1 and cluster2. This reciprocal create executes the create command on both the local cluster and the remote cluster. The cluster peer create command can use the hostnames of cluster2's intercluster addresses, the IP addresses of cluster2's intercluster LIFs or both. Note that the admin user's password was typed at the prompt, but was not displayed. The -local-name parameter is specified to create a local name used to identify the peer cluster in cases where the name of the peer cluster is not unique or not descriptive.

```
cluster1::> create -peer-addrs 10.98.191.193 -username admin -local-name locallyUniqueName
```

```
Peer Cluster Name  Cluster Serial Number  Availability  Authentication
------------------ ------------------------ -------------- ---------------
locallyUniqueName  1-80-000011           Available      absent
```

```
cluster1::> cluster peer show -instance
Peer Cluster Name: locallyUniqueName
Remote Intercluster Addresses: 10.98.191.193
Availability of the Remote Cluster: Available
Remote Cluster Name: cluster2
Active IP Addresses: 10.98.191.193
Cluster Serial Number: 1-80-000011
Address Family of Relationship: ipv4
Authentication Status Administrative: no-authentication
Authentication Status Operational: absent
Last Update Time: 02/05 21:05:41
IPspace for the Relationship: Default
Encryption for Inter-Cluster Communication: none
```

The following example create a peer relationship between cluster1 and cluster2 using system-generated passphrases:

```
cluster1::> cluster peer create -peer-addrs 10.98.191.193 -generate-passphrase
```

```
Passphrase: UCa+6lRVICXeL/gq1WrK7ShR
Peer Cluster Name: cluster2
Initial Allowed Vserver Peers: -
Expiration Time: 6/7/2017 09:16:10 +5:30
Intercluster LIF IP: 10.140.106.185

Warning: make a note of the passphrase - it cannot be displayed again.
```

```
cluster2::> cluster peer create -peer-addrs 10.140.106.185
```

Enter the passphrase:

```
Clusters cluster1 and cluster2 are peered.
```

```
cluster2::> cluster peer create -peer-addrs 10.140.106.185
```

The following example creates a cluster peer offer from cluster1 for an anonymous cluster using system-generated passphrase with offer expiration period of two days and the cluster2 uses the offer from cluster2 with the system-generated passphrase:

```
cluster1::> cluster peer create -generate-passphrase -offer-expiration 2days
```

```
Passphrase: UCa+6lRVICXeL/gq1WrK7ShR
Peer Cluster Name: Clus_7ShR (temporary generated)
Initial Allowed Vserver Peers: -
Expiration Time: 6/9/2017 08:16:10 +5:30
Intercluster LIF IP: 10.140.106.185

Warning: make a note of the passphrase - it cannot be displayed again.
```
Cluster "cluster1" creates an offer with `initial-allowed-vserver-peers` option set to Vservers "vs1" and "vs2". And the peer cluster "cluster2" uses the offer and creates peer relationship with cluster1, upon the successful peer relationship establishment. Vserver peer permission entries are created for the Vservers "vs1" and "vs2" in cluster "cluster1" for the peer cluster "cluster2". The following example describes the usage of `initial-allowed-vserver-peers` option in the cluster peer creation workflow:

```bash
cluster1::> cluster peer create -generate-passphrase -initial-allowed-vserver-peers vs1,vs2
  Passphrase: UCa+6lRVICxel/gq1WzK7ShR
  Peer Cluster Name: Clus_7ShR (temporary generated)
  Initial Allowed Vserver Peers: vs1,vs2
  Expiration Time: 6/7/2017 09:16:10 +5:30
  Intercluster LIF IP: 10.140.106.185
  Warning: make a note of the passphrase - it cannot be displayed again.
```

Cluster "cluster1" creates an offer with `initial-allowed-vserver-peers` option set to Vservers "vs1" and "vs2". And the peer cluster "cluster2" uses the offer and creates peer relationship with cluster1, upon the successful peer relationship establishment. Vserver peer permission entries are created for the Vservers "vs1" and "vs2" in cluster "cluster1" for the peer cluster "cluster2". The following example describes the usage of `initial-allowed-vserver-peers` option in the cluster peer creation workflow:

```bash
cluster1::> cluster peer create -generate-passphrase -initial-allowed-vserver-peers vs1,vs2
  Passphrase: UCa+6lRVICxel/gq1WzK7ShR
  Peer Cluster Name: Clus_7ShR (temporary generated)
  Initial Allowed Vserver Peers: vs1,vs2
  Expiration Time: 6/7/2017 09:16:10 +5:30
  Intercluster LIF IP: 10.140.106.185
  Warning: make a note of the passphrase - it cannot be displayed again.
```

```

```
cluster peer delete

Delete a cluster peer relationship

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The cluster peer delete command removes a peering relationship. It removes the relationship records, state data, and all associated jobs.

Before removing the relationship, the command verifies that no resources depend on the relationship. For example, if any SnapMirror relationships exist, the command denies the request to delete the peering relationship. You must remove all dependencies for the deletion to succeed. The cluster peer delete command removes only the local instance of the peer relationship. An administrator in the peer cluster must use the cluster peer delete command there as well to completely remove the relationship.

Parameters
-cluster <text> - Peer Cluster Name
  Use this parameter to specify the peering relationship to delete by specifying the name of the peered cluster.

Examples
This example shows a failed deletion due to a SnapMirror dependency.

```
cluster2::> cluster peer delete -cluster cluster1
Error: command failed: Unable to delete peer relationship. Reason: A SnapMirror source exists in this cluster
```

cluster peer modify

Modify cluster peer relationships

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The cluster peer modify command modifies the attributes of a peering relationship. When you modify a peer relationship and specify -peer-addrs, all of the remote addresses must respond, must be intercluster addresses, and must belong to the remote cluster that is being modified; or the modification request is denied.

Parameters
-cluster <text> - Peer Cluster Name
  Use this parameter to specify the peering relationship to modify by specifying the name of the peered cluster.

[-peer-addrs <Remote InetAddress>, ...] - Remote Intercluster Addresses
  Use this parameter to specify the names or IP addresses of the logical interfaces used for intercluster communication. Separate the addresses with commas. The list of addresses you provide replaces the existing list of addresses.

[-address-family {ipv4|ipv6}] - Address Family of Relationship
  Use this parameter to specify the address family of the names specified with the peer-addrs parameter.

[-timeout <integer>] - Operation Timeout (seconds) (privilege: advanced)
  Use this parameter to specify a timeout value for peer communications. Specify the value in seconds.
-auth-status-admin {no-authentication|revoked|use-authentication} - Authentication Status

Administrative

Use this parameter to adjust the authentication in use for the peer relationship. The defined values for this field are as follows.

- no-authentication - The cluster peer relationship uses no authentication.
- use-authentication - The cluster peer relationship is to be authenticated. After you use this value, you will be prompted for a passphrase to be used in determining a new authentication key, just as in the authenticated `cluster peer create` command or you can use the option `generate-passphrase` to automatically generate the passphrase.
- revoked - The cluster peer relationship is no longer to be trusted. Peering communication with this cluster peer is suspended until the two clusters set their `auth-status-admin` attributes either both to `no-authentication` or both to `use-authentication`.

Changes should be reflected on both clusters involved in a peering relationship.

-rpc-connect-timeout <integer> - Timeout for RPC Connect (seconds) (privilege: advanced)

Use this optional parameter to specify a timeout value for the RPC connect during peer communications. Specify the value in seconds.

-update-ping-timeout <integer> - Timeout for Update Pings (seconds) (privilege: advanced)

Use this optional parameter to specify a timeout value for pings while updating remote cluster information. Specify the value in seconds. This parameter applies only to cluster peer relationships using the IPv4 protocol.

-ipspace <IPspace> - IPspace for the Relationship

Use this optional parameter to specify that cluster peering communication for this remote cluster is to be done using local intercluster LIFs that are on ports in the named IPspace.

-generate-passphrase [true] - Use System-Generated passphrase

Use this optional parameter along with `-auth-status-admin` option's `use-authentication` to automatically generate the passphrase which can be used for cluster peer operation.

-encryption-protocol-proposed {none|tls-psk} - Encryption For Inter-Cluster Communication

Use this parameter to adjust the encryption of connections in use for the peer relationship. The defined values for this field are as follows.

- tls-psk - Use TLS with a Pre-Shared Key.
- none - Use no encryption.

Examples

This example modifies the peering relationship to use a new IP address in the remote cluster for intercluster communications and revoke authentication.

View existing cluster peer configuration using following command:

```
cluster1::> cluster peer show -instance
Peer Cluster Name: cluster2
Remote Intercluster Addresses: cluster2-d2, 10.98.234.246
Availability of the Remote Cluster: Available
Remote Cluster Name: cluster2
Active IP Addresses: 10.98.234.246, 10.98.234.243
Cluster Serial Number: 1-80-123456
Remote Cluster Nodes: cluster2-01, cluster2-02
Remote Cluster Health: true
Unreachable Local Nodes: -
Address Family of Relationship: ipv4
Authentication Status Administrative: use-authentication
Authentication Status Operational: ok
```
Modify the cluster peer configuration using following command:

```
cluster1::> cluster peer modify -cluster cluster2 -peer-addrs cluster2-d2,10.98.234.264 -auth-status-admin revoked
```

Warning: This will discard the authentication key.

Warning: You are removing authentication from the peering relationship with cluster "cluster2". Use the "cluster peer modify" command on cluster "cluster2" with the "-auth-status-admin no-authentication" parameter to complete authentication removal from the peering relationship.

Do you want to continue? {y|n}: y

The following example modifies the peering relationship to use authentication with `-generate-passphrase` option.

```
cluster1::> cluster peer modify -cluster cluster2 -auth-status-admin use-authentication -generate-passphrase
```

Notice: Use the below system-generated passphrase in the "cluster peer modify" command in the other cluster.

```
Passphrase: UCa+6lRVICxeL/gq1WrK7ShR
Expiration Time: 6/7/2017 09:16:10 +5:30
Peer Cluster Name: cluster2
```

Warning: make a note of the passphrase - it cannot be displayed again.

Until then, the operational authentication state of the relationship remains as "pending".

```
cluster1::> cluster peer offer show
```

<table>
<thead>
<tr>
<th>Peer Cluster Name</th>
<th>Authentication Creation</th>
<th>Expiration</th>
<th>Vserver Peers</th>
</tr>
</thead>
<tbody>
<tr>
<td>cluster2</td>
<td>ok-and-offer</td>
<td>6/7/2017 08:16:10</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>6/7/2017 09:16:10</td>
<td></td>
</tr>
</tbody>
</table>

Modify cluster peer relationship in cluster2 with use-authentication option and use the auto-generated passphrase.

```
cluster2::> cluster peer modify -cluster cluster2 -auth-status-admin use-authentication
```

Notice: Use a auto-generated passphrase or choose a passphrase of 8 or more characters. To ensure the authenticity of the peering relationship, use a phrase or sequence of characters that would be hard to guess.

Enter the passphrase:

Confirm the passphrase:

- `cluster peer create` on page 52
cluster peer modify-local-name

Modify the local name for a cluster peer

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The cluster peer modify-local-name command modifies the local name for a remote cluster. The new local name must be unique among all the local names for the remote clusters with which this cluster is peered.

Parameters
- `-name <text>` - Cluster Peer Name
  Use this parameter to specify the existing local name for a peer cluster.
- `-new-name <Cluster name>` - Cluster Peer Local Name
  Use this parameter to specify the new local name of the peer cluster. The new local name must conform to the same rules as a cluster name.

Examples
```
cluster2::> cluster peer modify-local-name -name cluster1 -new-name cluster1A
```

cluster identity modify on page 33

cluster peer ping

Initiate intercluster connectivity test

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The cluster peer ping command displays the status of the network mesh used by the peering relationship. The command checks the network connection to each remote IP address known by the cluster. This includes all intercluster addresses. It is possible for a known address to be not present during the ping. These addresses are not checked, but the absence is temporary.

The most useful parameters for diagnosing problems are `-count` and `-packet-size`. Use the `-count` and `-packet-size` parameters to diagnose problems similarly to how you use them with the standard ping utility.

To display network connection status within a cluster, use the network ping command.

Parameters
```
{-fields <fieldname>, ...}  
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use -fields ? to display the fields to specify.

{-instance}}  
If you specify the -instance parameter, the command displays detailed information about all fields.

-originating-node {<nodename> | local} - Node that Initiates Ping
Use this parameter to send the ping from the node you specify.

-destination-cluster <Cluster name> - Cluster to Ping
Use this parameter to specify the peer cluster you wish to ping.
```
[destination-node <Peer Node Name>] - Node to Ping in Destination Cluster

Use this parameter to specify a specific node in the destination cluster to ping.

[ip-address <IP Address>] - Active IP Address

Use this parameter to specify the active IP address you wish to ping.

[count <integer>] - Ping Count

Use this parameter to specify the number of requests to be sent to the destination.

[status {unknown_node|internal_error|unreachable|session_reachable|interface_reachable}] - Status of Ping Operation

Use this parameter to display only ping results that have the status you specify.

[timeout <integer>] - Ping Timeout in Seconds

Use this parameter to specify a timeout value in seconds for the ping operation.

[packet-size <integer>] - Size of Packet

Use this parameter to specify the number of data bytes to be sent in the ping packet.

[ttl <integer>] - Time to Live/ Number of Hops

Use this parameter to specify the maximum number of network hops a packet may make before it is considered a failure.

[response-time <double>] - Response Time (ms)

Use this parameter to display only nodes that have the response time (in milliseconds) that you specify. This parameter is most useful when specified with a range of values, such as >500

### Examples

This example shows a ping of cluster1 and cluster2 from cluster2. All nodes are reachable.

```
cluster2::> cluster peer ping
Node: node1                  Destination Cluster: cluster2
  Destination Node IP Address       Count  TTL RTT(ms) Status
  ---------------- ---------------- ----- ---- ------- -------------------------
  node1            10.98.228.230        1  255   0.209 interface_reachable
  node2            10.98.228.234        1  255    0.42 interface_reachable
Node: node2                  Destination Cluster: cluster2
  Destination Node IP Address       Count  TTL RTT(ms) Status
  ---------------- ---------------- ----- ---- ------- -------------------------
  node1            10.98.228.230        1  255   0.358 interface_reachable
  node2            10.98.228.234        1  255    0.17 interface_reachable
Node: node1                  Destination Cluster: cluster1
  Destination Node IP Address       Count  TTL RTT(ms) Status
  ---------------- ---------------- ----- ---- ------- -------------------------
  node3            10.98.229.22         1  255   0.336 interface_reachable
  node4            10.98.229.29         1  255   0.354 interface_reachable
Node: node2                  Destination Cluster: cluster1
  Destination Node IP Address       Count  TTL RTT(ms) Status
  ---------------- ---------------- ----- ---- ------- -------------------------
  node3            10.98.229.22         1  255   0.354 interface_reachable
  node4            10.98.229.29         1  255   0.336 interface_reachable
6 entries were displayed.
```
Description
The `cluster peer show` command displays information about the peering relationships between the current cluster and other clusters. Cluster peering enables independent clusters to coordinate and exchange data.

Parameters

`{[-fields <fieldname>, ...]` If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `'-fields ?'` to display the fields to specify.

`[-instance]` If you specify the `-instance` parameter, the command displays detailed information about all fields.

`[-cluster <text>]` - Peer Cluster Name
Selects the peered clusters that match this parameter value.

`[-cluster-uuid <UUID>]` - Cluster UUID (privilege: advanced)
Selects the peered clusters that match this parameter value.

`[-peer-addrs <Remote InetAddress>, ...]` - Remote Intercluster Addresses
Selects the peered clusters that match this parameter value (remote-host name or IP address).

`[-availability <availability>]` - Availability of the Remote Cluster
Selects the peered clusters that match this parameter value. This parameter can have four different values:

- Available - The peer cluster availability status will be `Available` only if all the nodes in the local cluster are able to contact all the nodes in the remote cluster.
- Partial - The peer cluster availability status will be `Partial` only if some nodes in the local cluster are not able to contact some or all nodes in the peer cluster.
- Unavailable - The peer cluster availability status will be `Unavailable` only if all the nodes in the local cluster are not able to contact any node in the peer cluster.
- Pending - The peer cluster availability status will be `Pending` while the system is creating in-memory health data.
- Unidentified - The peer cluster availability status will be Unidentified if the cluster peer offer is created for an anonymous cluster and is unused. When the offer is used, then the availability will get changed to any of the above mentioned status.

Note: If one or more nodes in the local cluster are offline or unreachable, then those nodes are not used to determine the availability status for the remote nodes.

`[-rcluster <text>]` - Remote Cluster Name
Selects the peered clusters that match this parameter value.

`[-ip-addrs <Remote InetAddress>, ...]` - Active IP Addresses
Selects the peered clusters that match this parameter value.

`[-serialnumber <Cluster Serial Number>]` - Cluster Serial Number
Selects the peered clusters that match this parameter value.

`[-remote-cluster-nodes <text>, ...]` - Remote Cluster Nodes
Selects the peered clusters that match this parameter value.

`[-remote-cluster-health {true|false}]` - Remote Cluster Health
Selects the peered clusters that match this parameter value.

- true - This means that there is cluster quorum in the peer cluster.
• false - This means that there is no cluster quorum in the peer cluster.

[-unreachable-local-nodes <text>, ...] - Unreachable Local Nodes
   Selects the peered clusters that match this parameter value.

[-timeout <integer>] - Operation Timeout (seconds) (privilege: advanced)
   Selects the peered clusters that match this parameter value.

[-address-family {ipv4|ipv6}] - Address Family of Relationship
   Selects the peered clusters that have a relationship established using this protocol.

[-auth-status-admin {no-authentication|revoked|use-authentication}] - Authentication Status Administrative
   Selects the peered clusters that match this parameter value, which must be chosen from the following values.
   • no-authentication - The cluster peer relationship uses no authentication.
   • use-authentication - The cluster peer relationship is authenticated.
   • revoked - The cluster peer relationship is revoked until agreement can be reached.

[-auth-status-operational {ok|absent|pending|expired|revoked|declined|refused|ok-and-offer|absent-but-offer|revoked-but-offer|key-mismatch|intent-mismatch|incapable}] - Authentication Status Operational
   Selects the peered clusters that match this parameter value, which must be one of the following values.
   • ok - The clusters both use authentication and they have agreed on an authentication key.
   • absent - The clusters agree not to use authentication.
   • pending - This cluster has made an outstanding offer to authenticate with the other cluster, but agreement has not yet been reached.
   • expired - This cluster's offer to authenticate with the other cluster expired before agreement was reached.
   • revoked - This cluster has revoked any prior authentication agreement.
   • declined - The other cluster has revoked the authentication agreement and is declining to communicate with this cluster.
   • refused - The other cluster actively refuses the communication attempts, perhaps because its part of the peering relationship has been deleted.
   • ok-and-offer - The clusters agree on an authentication key and are using it. In addition, this cluster has made an outstanding offer to re-authenticate with the other cluster.
   • absent-but-offer - The clusters currently agree that neither side requires authentication of the other, but this cluster has made an outstanding offer to authenticate.
   • revoked-but-offer - This cluster has revoked any authentication agreement, but it has made an outstanding offer to authenticate.
   • intent-mismatch - The two clusters disagree on whether authentication is required.
   • key-mismatch - The two clusters both believe that they are authenticated, but one of the shared secrets has become corrupted.
   • incapable - The other cluster is no longer running a version of Data ONTAP that supports authenticated cluster peering.

[-rpc-connect-timeout <integer>] - Timeout for RPC Connect (privilege: advanced)
   Selects the peered clusters that match this parameter value.
[-update-ping-timeout <integer>] - Timeout for Update Pings (privilege: advanced)
Selects the peered clusters that match this parameter value.

[-last-updated <MM/DD/YYYY HH:MM:SS>] - Last Update Time
Selects the peered clusters that match this parameter value.

[-ipspace <IPspace>] - IPspace for the Relationship
Selects the peered clusters whose relationships are to cross the named local IPspace. The default value is the IPspace name "Default". In relationships created before ONTAP 8.3.1, the initial value is "-" and is not updated to "Default" until an action is taken on a cluster peer relationship, such as creating, modifying, or deleting a relationship.

[-encryption-protocol-proposed {none|tls-psk}] - Proposed Setting for Encryption of Inter-Cluster Communication
Selects the peered clusters that match the value of this parameter, that is, whether they are proposing to encrypt their cross-cluster communication or not.

[-encryption-protocol {none|tls-psk}] - Encryption Protocol For Inter-Cluster Communication
Selects the peered clusters that match the value of this parameter, that is, whether they are encrypting their cross-cluster communication or not.

Examples
This example shows the output of the cluster peer show command when all nodes in the local cluster are able to contact all nodes in the remote peer cluster. Additionally, the peer relationship is authenticated and operating correctly.

```
cluster1::> cluster peer show
Peer Cluster Name          Cluster Serial Number Availability Authentication
------------------------- --------------------- -------------- --------------
cluster2                  1-80-123456           Available      ok
```

Detailed information for this scenario is shown below.

```
cluster1::> cluster peer show -instance
Peer Cluster Name: cluster2
Remote Intercluster Addresses: cluster2-d2, 10.98.234.246
Availability of the Remote Cluster: Available
Remote Cluster Name: cluster2
Active IP Addresses: 10.98.234.246, 10.98.234.243
Cluster Serial Number: 1-80-123456
Remote Cluster Nodes: cluster2-01, cluster2-02
Remote Cluster Health: true
Unreachable Local Nodes: -
Address Family of Relationship: ipv4
Authentication Status Administrative: use-authentication
Authentication Status Operational: ok
Last Update Time: 02/05 21:05:41
IPspace for the Relationship: Default
Encryption for Inter-Cluster Communication: none
```

This example shows the output of the cluster peer show command when some nodes in the local cluster are not able to contact some or all of the nodes in the remote peer cluster.

```
cluster1::> cluster peer show
Peer Cluster Name          Cluster Serial Number Availability Authentication
------------------------- --------------------- -------------- --------------
cluster2                  1-80-123456           Available      ok
```

Detailed information for this scenario is shown below.

```
cluster1::> cluster peer show -instance
Peer Cluster Name: cluster2
Remote Intercluster Addresses: cluster2-d2, 10.98.234.246
```

cluster peer commands
### Availability of the Remote Cluster: Partial

- **Remote Cluster Name:** cluster2
- **Active IP Addresses:** 10.98.234.246, 10.98.234.243
- **Cluster Serial Number:** 1-80-123456
- **Remote Cluster Nodes:** cluster2-01, cluster2-02
- **Remote Cluster Health:** false
- **Unreachable Local Nodes:** -
- **Address Family of Relationship:** ipv4
- **Authentication Status Administrative:** use-authentication
- **Authentication Status Operational:** ok
- **Last Update Time:** 02/05 21:05:41
- **IP space for the Relationship:** Default
- **Encryption for Inter-Cluster Communication:** none

This example shows the output of the cluster peer show command when some nodes in the local cluster cannot be contacted from the node where the command is executed, but all the other nodes including node on which command is executed are able to contact all nodes in the remote peer cluster.

**cluster1::> cluster peer show**

<table>
<thead>
<tr>
<th>Peer Cluster Name</th>

cluster1::> cluster peer show -instance

    Peer Cluster Name: Clus_4gHR
Remote Intercluster Addresses: -
    Availability of the Remote Cluster: Unidentified
    Remote Cluster Name: Clus_4gHR
    Active IP Addresses: 10.98.234.246, 10.98.234.243
    Cluster Serial Number: -
    Remote Cluster Nodes: -

Commands: Manual Page Reference
Cluster Peer Connection Commands

The connection directory

The `cluster peer connection` commands provide you with the ability to observe, and to some extent manage, the connections created on behalf of cluster peering, both for control and data access.

**cluster peer connection show**

Show current peering connections for a cluster

**Availability:** This command is available to `cluster` administrators at the `admin` privilege level.

**Description**

The `cluster peer connection show` command displays information about the current TCP connections and how they are supporting the set of peering relationships.

**Parameters**

{`-fields <fieldname>, ...`

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

`[-instance]`

If you specify the `-instance` parameter, the command displays detailed information about all fields.

`[-cluster-name <text>] - Remote Cluster`

Selects the connections associated with the named peered cluster.

`[-node {<nodename>|local}] - Node`

Selects the connections hosted by the given node.

`[-connection-type {mgmt-client|mgmt-server|data}] - Cluster Peering Connection Type`

Selects the connections of the named type. This parameter can have one of three different values:

- Mgmt-client - Management-plane client connections, created so that this node may make management-plane requests of other nodes.
- Mgmt-server - Management-plane server connections, over which this node services requests made by other nodes' mgmt-client connections.
- Data - Connections made between data-planes of different nodes.

`[-index <integer>] - Index of Connection`

Selects the connections with the given index value.

`[-cluster-uuid <UUID>] - Cluster UUID (privilege: advanced)`

Selects the connections to the cluster with the given cluster UUID.

`[-auth-status-admin {no-authentication|revoked|use-authentication}] - Authentication Status Administrative`

Selects connections to the peered clusters whose intended authentication matches this parameter value.
[-auth-status-operational {ok|absent|pending|expired|revoked|declined|refused|ok-and-offer|absent-but-offer|revoked-but-offer|key-mismatch|intent-mismatch|incapable}] - Authentication Status Operational

Selects connections to the peered clusters whose authentication state matches this parameter value.

[-authenticated {true|false}] - Authenticated

Selects connections that have been authenticated, or not, according to this parameter value.

[-port <integer>] - Network Port

Selects the connections whose port matches this parameter value.

[-idle <[<integer>h] [<integer>m] [<integer>s]>] - Idle Time

Selects the connections whose idle times match this parameter value.

[-address <IP Address>] - Remote Network Address

Selects the connections that have this parameter value as the remote network address.

---

**Examples**

This example shows the output of the `cluster peer connection show` command.

```
cluster1::> cluster peer connection show
cluster2  node1                  Connection Type  Auth  Encrypt  Idle  Remote Address
--- -----------------  ---------------  ----- ------- ------- --------------
data    true  true   6s    10.10.10.100
data    true  true   7s    10.10.10.100
data    true  true   20s   10.10.10.100
data    true  true   7s    10.10.10.100
data    true  true   7s    10.10.10.100
data    true  true   11s   10.10.10.100
data    true  true   11s   10.10.10.100
data    true  true   48s   10.10.10.100
data    true  true   48s   10.10.10.100
data    true  true   37s   10.10.10.100
data    true  true   37s   10.10.10.100
12 entries were displayed.
```

---

**cluster peer health commands**

The health directory

**cluster peer health show**

Check peer cluster health

**Availability:** This command is available to `cluster` administrators at the `admin` privilege level.

**Description**

The `cluster peer health show` command displays information about the health of the nodes in peer clusters from the perspective of the nodes in the local cluster. The command obtains health information by performing connectivity and status probes of each peer cluster's nodes from each node in the local cluster.

To enable quick access to remote cluster health information, remote cluster health status is periodically checked and cached. These cached results enable users and system features to quickly assess the availability of remote resources. By default, this command accesses cached results. Use the `-bypass-cache true` option to force a current, non-cached check of remote cluster health.
Parameters

{ [-fields <fieldname>, ...] }  If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use -fields ? to display the fields to specify.

[-instance ]  If you specify the -instance parameter, the command displays detailed information about all fields.

[-originating-node (<nodename> | local)] - Local Node
Selects the node that matches this parameter value.

[-destination-cluster <Cluster name>] - Peer Cluster
Selects the cluster that matches this parameter value.

[-destination-node <Peer Node Name>] - Peer Node
Selects the node that matches this parameter value.

[-destination-cluster-uuid <UUID>] - Peer UUID
Selects the cluster that matches this parameter value.

[-data-ping (unknown_node|internal_error|unreachable|session_reachable|interface_reachable)] - Status of Data Ping Operation
Selects the nodes that match this parameter value.

[-icmp-ping (unknown_node|internal_error|unreachable|session_reachable|interface_reachable)] - Status of ICMP Ping Operation
Selects the nodes that match this parameter value.

[-node-health (true|false)] - RDB Health of the Node
Selects the nodes that match this parameter value (true means healthy).

[-cluster-health (true|false)] - Cluster Health
Selects the nodes that match this parameter value (true means healthy).

[-availability (true|false)] - Communication Indicator
Selects the nodes that match this parameter value (true means communicating).

[-bypass-cache (true|false)] - Bypass Cache and Determine Health
Bypasses cached results to determine current cluster health (true means bypass the cache). Cached results may not be current, but they are displayed more quickly.

[-last-updated <MM/DD/YYYY HH:MM:SS>] - Last Update Time
Selects the nodes that match this parameter value.

Examples

The following example shows typical output for this command in a cluster of two nodes that has a peer cluster of two nodes.

```
cluster1::> cluster peer health show
Node       Cluster-Name                 Node-Name
---------- --------------------------- --------- --------------- ------------
node1
Data: interface_reachable     node3
ICMP: interface_reachable    true     true    true
Data: interface_reachable     node4
ICMP: interface_reachable    true     true    true
```

cluster peer commands 73
The following example shows detailed health information for node3 in cluster2 from the perspective of node1 in cluster1.

```
cluster1::> cluster peer health show -originating-node node1 -destination-cluster cluster2 -destination-node node3 -instance
```

```
Local Node: node1
Peer Cluster: cluster2
Peer Node: node3
Peer UUID: 5e4befb2-1f36-11d0-98c9-123476563412
Status of Data Ping Operation: interface_reachable
Status of ICMP Ping Operation: interface_reachable
RDB health of the node: true
Cluster Health: true
Communication Indicator: true
Last Update Time: 02/06 18:58:38
```

### Cluster Peer Offer Commands

Manage offers to authenticate cluster peer relationships

The `cluster peer offer` commands provide you with the ability to manage the authentication offers that can be created by the `cluster peer create` and `cluster peer modify` commands.

**Related references**

- `cluster peer create` on page 52
- `cluster peer modify` on page 58

### cluster peer offer cancel

Cancel the outstanding offer to authenticate with a peer cluster

**Availability:** This command is available to cluster administrators at the `admin` privilege level.

**Description**

The `cluster peer offer cancel` command cancels an outstanding offer to authenticate with a potentially peered cluster. After the command completes, the given cluster can no longer establish authentication using the given authentication offer.

**Parameters**

- `<cluster <text>>` - Peer Cluster Name

  Use this parameter to specify which offer should be cancelled, by specifying the name of the cluster to which the offer is extended.

**Examples**

The following example cancels the authentication offer to cluster2.

```
cluster1::> cluster peer offer cancel -cluster cluster2
```

### cluster peer offer modify

Modify an outstanding offer to authenticate with a peer cluster

**Availability:** This command is available to cluster administrators at the `admin` privilege level.
Description
The `cluster peer offer modify` command modifies the outstanding offer to authenticate with a potentially peered cluster. Every authentication offer has an expiration time, after which the offer will no longer be honored. This command is used to change that expiration time. To cancel the offer outright, use the `cluster peer offer cancel` command instead.

Parameters
- `--cluster <text>` - Peer Cluster Name
  Use this parameter to specify the offer to be modified by indicating the name of the cluster to which it has been extended.

- `--offer-expiration (MM/DD/YYYY HH:MM:SS | {1..7}days | {1..168}hours | PnDTnHnMnS | PnW)` - Authentication Offer Expiration Time
  Use this parameter to specify the new expiration time for the offer.

- `--initial-allowed-vserver-peers <vserver name>, ...` - Vservers Initially Allowed for Peering
  Use this optional parameter to specify the list of Vservers for which reciprocal Vserver peering with peer cluster should be enabled.

Examples
This example modifies the expiration time for the authentication offer to push it out by an hour.

```
cluster1::> cluster peer offer show
Peer Cluster Name       Authentication Creation            Expiration
----------------------- -------------- ------------------- -------------------
cluster1::> cluster peer offer modify --cluster cluster2 --offer-expiration "7/23/2013 16:45:47"
cluster1::> cluster peer offer show
Peer Cluster Name       Authentication Creation            Expiration
----------------------- -------------- ------------------- -------------------
```

Related references
`cluster peer offer cancel` on page 74

`cluster peer offer show`
Display outstanding offers to authenticate with a peer cluster

Availability: This command is available to `cluster` administrators at the `admin` privilege level.

Description
The `cluster peer offer show` command displays information about authentication offers still pending with potential peer clusters. By default, the command displays information about all unexpired offers made by the local cluster.

To display detailed information about a specific offer, run the command with the `--cluster` parameter.

Parameters
```
{ [--fields <fieldname>, ... ]
  If you specify the `--fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `--fields` to display the fields to specify.
  |
  [ [--instance ]
  If you specify the `--instance` parameter, the command displays detailed information about all fields.
```

cluster peer commands

75
[-cluster <text>] - Peer Cluster Name
Selects the offer that matches this parameter value.

[-auth-status-operational {ok|absent|pending|expired|revoked|declined|refused|ok-and-offer|
absent-but-offer|revoked-but-offer|key-mismatch|intent-mismatch|incapable}] - Authentication Status Operational
Selects the offers that match this parameter value.

[-offer-creation <MM/DD/YYYY HH:MM:SS>] - Authentication Offer Creation Time
Selects the offers that match this parameter value.

[-offer-expiration (MM/DD/YYYY HH:MM:SS | {1..7}days | {1..168}hours | PnDTnHnMnS | PnW)] -
Authentication Offer Expiration Time
Selects the offers that match this parameter value.

[-initial-allowed-vserver-peers <Vserver Name>, ...] - Vservers Initially Allowed for Peering
Selects the offers that match this parameter value.

[-offer-creator <text>] - Authentication Offer Creator
Selects the offers that match this parameter value.

[-encryption-protocol-proposed {none|tls-psk}] - Encryption Protocol to Be Used For the Relationship
Selects the offers that match this parameter value.

Examples
The following example displays information about the outstanding authentication offers:

```
cluster1::> cluster peer offer show
 Allowed
Peer Cluster Name       Authentication Creation            Expiration          Vserver Peers
----------------------- -------------- ------------------- ------------------- --------------
```

cluster peer policy commands
Manage the policy configuration of the cross-cluster relationship facility

cluster peer policy modify
Modify the policy configuration for the cluster peering service

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The cluster peer policy modify command modifies the prevailing policy settings. One setting governs whether unauthenticated cluster peer relationships can exist. The other setting specifies a minimum length for passphrases.

Parameters
[-is-unauthenticated-access-permitted {true|false}] - Is Unauthenticated Cluster Peer Access Permitted
Use this parameter to specify whether unauthenticated peering relationships are allowed to exist. Setting the parameter value to true allows such relationships to exist. Setting the value to false prevents both the creation of unauthenticated peering relationships as well as the modification of existing peering relationships to be unauthenticated. Setting the value to false is not possible if the cluster currently is in any unauthenticated relationships.
[-passphrase-minlength <integer>] - Passphrase Length Minimum

Use this parameter to specify a minimum length for passphrases as given to the `cluster peer create` or `cluster peer modify` commands in the future. The default value for this parameter is 8.

[-is-unencrypted-access-permitted {true|false}] - Is Unencrypted Cluster Peer Access Permitted

Use this parameter to specify whether peering relationships that do not use encryption are allowed to exist. Setting the parameter value to `true` allows such relationships to exist. Setting the value to `false` prevents the creation of unauthenticated peering relationships and the modification of existing peering relationships to be unauthenticated, as well as preventing unencrypted peering relationships from being created and the modification of existing peering relationships to be unencrypted. Setting the value to `false` is not possible if the cluster currently is in any unauthenticated or unencrypted relationships.

**Examples**

This example modifies the peering policy to disallow unauthenticated intercluster communications.

```
cluster1::> cluster peer policy show
Is Unauthenticated Cluster Peer Communication Permitted: true
Minimum Length for a Passphrase: 8
cluster1::> cluster peer policy modify -is-unauthenticated-access-permitted false
cluster1::> cluster peer policy show
Is Unauthenticated Cluster Peer Communication Permitted: false
Minimum Length for a Passphrase: 8
```

**Related references**

`cluster peer create` on page 52

**cluster peer policy show**

Display the policy configuration for the cluster peering service

**Availability:** This command is available to cluster administrators at the `admin` privilege level.

**Description**

The `cluster peer policy show` command displays the prevailing cluster peer authentication policy. There are two policies at present: one to control whether any cluster peer relationships can be unauthenticated, and one to control the minimum length for a passphrase. If the policy is set to preclude unauthenticated peering relationships, then unauthenticated relationships cannot be created inadvertently. Passphrases of less than the minimum length may not be used. By default, this minimum length is set to 8, so passphrases must be 8 characters long or longer.

**Examples**

This example shows the cluster peer policy when unauthenticated relationships may not be created inadvertently.

```
cluster1::> cluster peer policy show
Is Unauthenticated Cluster Peer Communication Permitted: false
Minimum Length for a Passphrase: 9
Is Unencrypted Cluster Peer Communication Permitted: true
```

**cluster quorum-service commands**

Manage the quorum options of the cluster
cluster quorum-service options commands

The options directory

cluster quorum-service options modify

Modify the settings for cluster quorum-service

Availability: This command is available to cluster administrators at the advanced privilege level.

Description

The cluster quorum-service options modify command modifies the values of cluster quorum services options.

Parameters

[-ignore-quorum-warning-confirmations {true|false}] - Whether or Not Warnings Are Enabled

Specifies whether cluster quorum warnings and confirmations should be ignored when cluster operations could negatively impact cluster quorum:

- Halting a node (system node halt)
- Rebooting a node (system node reboot)
- Issuing a planned takeover (storage failover takeover)

The default setting is false.

Examples

The following example shows the usage of this command:

```
cluster1::> set advanced
Warning: These advanced commands are potentially dangerous; use them only when directed to do so by NetApp personnel.
Do you want to continue? {y|n}: y
cluster1::*> cluster quorum-service options modify -ignore-quorum-warning-confirmations true
```

system node halt on page 1266
system node reboot on page 1269
storage failover takeover on page 1012

cluster quorum-service options show

Display the settings for cluster quorum-service

Availability: This command is available to cluster administrators at the advanced privilege level.

Description

The cluster quorum-service options show command displays the values of cluster quorum services options.

Examples

The following example demonstrates showing the state of ignore-quorum-warning-confirmations when it is false and true.
cluster ring commands
Display information about cluster replication rings

cluster ring show
Display cluster node member's replication rings

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
The cluster ring show command displays a cluster's ring-replication status. Support personnel might ask you to run this command to assist with troubleshooting.

Parameters
{ [-fields <fieldname>,...]
   If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use `-fields ?' to display the fields to specify.
   
   [-instance ]
   If you specify the -instance parameter, the command displays detailed information about all fields.

   [-node {<nodename>|local}] - Node
   Selects the rings that match this parameter value.

   [-unitname {mgmt|vldb|vifmgr|bcomd|crs|availd}] - Unit Name
   Selects the rings that match this parameter value. Possible values are:
   • mgmt - The management application
   • vldb - The volume location database
   • vifmgr - The virtual-interface manager
   • bcomd - The SAN management daemon
   • crs - The configuration replication service

   [-online {master|secondary|offline}] - Status
   Selects the rings that match this parameter value.

   [-epoch <integer>] - Epoch
   Selects the rings that match this parameter value.
[-master <nodename>] - Master Node
Selects the rings that match this parameter value.

[-local <nodename>] - Local Node
Selects the rings that match this parameter value.

[-db-epoch <integer>] - DB Epoch
Selects the rings that match this parameter value.

[-db-trnxs <integer>] - DB Transaction
Selects the rings that match this parameter value.

[-num-online <integer>] - Number Online
Selects the rings that match this parameter value.

[-rdb-uuid <UUID>] - RDB UUID
Selects the rings that match this parameter value.

Examples
The following example displays information about all replication rings in a two-node cluster:

```
cluster1:*> cluster ring show
Node      UnitName Epoch   DB Epoch DB Trnxs Master    Online
--------- -------- -------- -------- -------- --------- ---------
node0     mgmt     1        1        1068     node0     master
node0     vldb     1        1        98       node0     master
node0     vifmgr   1        1        350      node0     master
node0     bcomd    1        1        56       node0     master
node0     crs      1        1        88       node0     master
node1     mgmt     1        1        1068     node0     secondary
node1     vldb     1        1        98       node0     secondary
node1     vifmgr   1        1        350      node0     secondary
node1     bcomd    1        1        56       node0     secondary
node1     crs      1        1        88       node0     secondary
10 entries were displayed.
```

Cluster Statistics Commands

The statistics directory

The `cluster statistics` command displays statistics of Data ONTAP 8 systems.

`cluster statistics show`

Display cluster-wide statistics

Availability: This command is available to `cluster` administrators at the `admin` privilege level.

Description

The `cluster statistics show` command displays the following information. Each item lists the current value and, if applicable, the change (delta) from the previous reported value.

- CPU busy percentage
- Average of CPU busy percentage (advanced privilege level only)
- Total number of NFS and CIFS operations
- Number of NFS operations
• Number of CIFS operations
• Number of cache operations (advanced privilege level only)
• Total amount of network data received (advanced privilege level only)
• Total amount of network data sent (advanced privilege level only)
• Number of packets received (advanced privilege level only)
• Number of packets sent (advanced privilege level only)
• Busy percentage for the data network
• Amount of data received on the data network
• Amount of data sent on the data network
• Busy percentage for the cluster network
• Amount of data received on the cluster network
• Amount of data sent on the cluster network
• Amount of data read from disk
• Amount of data written to disk

At the diagnostic privilege level, the command displays the following information:
• Average of CPU busy percentage
• CPU busy percentage
• Total number of operations
• Number of NFS operations
• Number of CIFS operations
• Number of 7M Fcache operations
• Number of SpinFS operations
• Total amount of network traffic received
• Total amount of network traffic sent
• Percentage of data-network utilization
• Amount of data-network traffic received
• Amount of data-network traffic sent
• Percentage of cluster-network utilization
• Amount of cluster-network traffic received
• Amount of cluster-network traffic sent
• Amount of data read from disk
• Amount of data written to disk
• Number of packets received
• Number of packets sent
Examples
The following example displays cluster statistics:

```
cluster1::> cluster statistics show

<table>
<thead>
<tr>
<th>Counter</th>
<th>Value</th>
<th>Delta</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPU Busy:</td>

```

cluster time-service commands
Manage cluster time services

cluster time-service ntp commands
Manage cluster Network Time Protocol (NTP) service

cluster time-service ntp key commands
The key directory

cluster time-service ntp key create
Create an NTP symmetric authentication key

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The `cluster time-service ntp key create` command creates a cryptographic key that can be used to verify that Network Time Protocol (NTP) packets are coming from a configured NTP server.

To use the created key it must be assigned to the required NTP server configuration using the `cluster time-service ntp server create` or `cluster time-service ntp server modify` commands.

Note: The id, key-type and value must all be configured identically on both the ONTAP cluster and the external NTP time server for the cluster to be able to synchronize time to that server.

Parameters

- `-id <integer>` - NTP Symmetric Authentication Key ID
  Uniquely identifies this key in the cluster. Must be an integer between 1 and 65535.

- `-type <sha1>` - NTP Symmetric Authentication Key Type
  The cryptographic algorithm that this key is used with. Only SHA1 is currently supported.
-value <text> - NTP Symmetric Authentication Key Value

A 40 character hexadecimal digit string that represents a cryptographic key that is shared with the NTP server.

Examples

The following example creates a new SHA-1 NTP symmetric authentication key.

```
cluster1::> cluster time-service ntp key create 1 sha1 2e874852e7d41cda65b23915aa5544838b366c51
```

Related references

- `cluster time-service ntp server create` on page 86
- `cluster time-service ntp server modify` on page 87

**cluster time-service ntp key delete**

Delete an NTP symmetric authentication key

**Availability:** This command is available to `cluster` administrators at the `admin` privilege level.

**Description**

Delete an NTP symmetric authentication key.

**Note:** It is not possible to delete a key that is referenced in an existing NTP server configuration. Remove all references to this key using the `cluster time-service ntp server modify` or `cluster time-service ntp server delete` commands before attempting to delete the key using this command.

**Parameters**

- `-id <integer>` - NTP Symmetric Authentication Key ID
  
  Unique identifier of this key in the cluster.

Examples

The following example deletes the NTP key with ID 1.

```
cluster1::> cluster time-service ntp key delete 1
```

Related references

- `cluster time-service ntp server modify` on page 87
- `cluster time-service ntp server delete` on page 87

**cluster time-service ntp key modify**

Modify an NTP symmetric authentication key

**Availability:** This command is available to `cluster` administrators at the `admin` privilege level.

**Description**

The `cluster time-service ntp key modify` command modifies a Network Time Protocol (NTP) symmetric authentication key.

**Parameters**

- `-id <integer>` - NTP Symmetric Authentication Key ID
  
  Unique identifier of this key in the cluster.
[-type <sha1>] - NTP Symmetric Authentication Key Type

The cryptographic algorithm that this key is used with. Only SHA1 is currently supported.

[-value <text>] - NTP Symmetric Authentication Key Value

A 40 character hexadecimal digit string that represents a cryptographic key that is shared with the NTP server.

Examples

The following example modifies the NTP key with ID 1 to have a new value.

```
cluster1::> cluster time-service ntp key modify 1 -value 2e874852e7d41cda65b23915aa554483b366c51
```

class time-service ntp key show

Display NTP symmetric authentication keys

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The `cluster time-service ntp key show` command displays the configured Network Time Protocol (NTP) symmetric authentication keys.

Parameters

[-fields <fieldname>, ...]

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

[-instance]

If you specify the `-instance` parameter, the command displays detailed information about all fields.

[-id <integer>] - NTP Symmetric Authentication Key ID

If this parameter is specified, the command displays the keys that match the specified key ID.

[-type <sha1>] - NTP Symmetric Authentication Key Type

If this parameter is specified, the command displays the keys that match the specified key type.

[-value <text>] - NTP Symmetric Authentication Key Value

If this parameter is specified, the command displays the keys that match the specified value.

Examples

The following example displays information about the NTP authentication keys in the cluster:

```
cluster1::> cluster time-service ntp key show
ID      Type       Value
------  ---------  ----------------------------------------
 2       sha1       5a01120580b5a6ade6ebcd5bad7673fdd6db0113
 10      sha1       1f48d2e6f02f17e3f8fa8798c77af101df29642
2 entries were displayed.
```

class time-service ntp security commands

The security directory
**cluster time-service ntp security modify**

Modify NTP security settings

**Availability:** This command is available to cluster administrators at the *advanced* privilege level.

**Description**
The `cluster time-service ntp security modify` command allows setting of security parameters related to the Network Time Protocol (NTP) subsystem.

**Parameters**

[-is-query-enabled *(true|false)*] - Is Querying of NTP Server Enabled?

Setting this parameter to *true* allows querying of the NTP subsystem from systems external to the cluster. For example, querying a node using the standard "ntpq" command can be enabled by this command. The default setting is *false* to protect against possible security vulnerabilities. If querying of the NTP subsystem is disabled, the `cluster time-service ntp status show` command can be used to obtain similar information. Although querying of the NTP subsystem from external hosts can be disabled with this command, executing a local query to the localhost address is always enabled.

**Examples**
The following example enables the querying of the NTP subsystem from clients external to the cluster:

```
cluster-1::> cluster time-service ntp security modify -is-query-enabled true
```

**Related references**

- `cluster time-service ntp status show` on page 90

**cluster time-service ntp security show**

Display NTP security settings

**Availability:** This command is available to cluster administrators at the *advanced* privilege level.

**Description**
The `cluster time-service ntp security show` command displays the configuration of security features related to the Network Time Protocol (NTP) subsystem.

**Examples**
The following example displays the NTP security configuration of the cluster:

```
cluster1::> cluster time-service ntp security show
External queries enabled?: true
```

**cluster time-service ntp server commands**
The server directory
cluster time-service ntp server create

Add a NTP Server

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The cluster time-service ntp server create command associates the cluster with an external network time server for time correction and adjustment by using the Network Time Protocol (NTP).

The command resolves the time server host name to an IP address and performs several validation checks. If an error is detected during validation, it is reported.

The validation checks performed by this command include the following:
- The NTP reply to an NTP query with the specified protocol version.
- The NTP reply indicates that the external time server is synchronized to another time server.
- The distance and dispersion of the NTP reply from the "root" or source clock are within the required limits.

Parameters

-server <text> - NTP Server Host Name, IPv4 or IPv6 Address

This parameter specifies the host name or IP address of the external NTP server that is to be associated with the cluster for time correction and adjustment.

[-version {3|4|auto}] - NTP Version for Server (default: auto)

Use this parameter to optionally specify the NTP protocol version that should be used for communicating with the external NTP server. If the external NTP server does not support the specified protocol version, time exchange cannot take place.

The supported values for this parameter include the following:
- 3 - Use NTP protocol version 3, which is based on Internet Standard request for comments (RFC) #1305.
- 4 - Use NTP protocol version 4, which is based on Internet Standard RFC #5905.
- auto - Have Data ONTAP select the NTP protocol version.

The default setting is auto.

[-is-preferred {true|false}] - Is Preferred NTP Server (default: false) (privilege: advanced)

Use this parameter to optionally specify whether the external NTP server is the primary time source for correcting and adjusting the cluster time. The responses from this source are used unless its time is outside the accepted selection range.

The default setting is false.

You use this parameter when a high quality radio (or GPS) based time server is being used with a set of non-radio based backup time servers.

[-key-id <integer>] - NTP Symmetric Authentication Key ID

Use this parameter to optionally enable NTP symmetric authentication key for communication with the specified time server. The ID must refer to a key created by the cluster time-service ntp key create command and must be a key with the same ID and value as one configured on the specified time server.

Examples
The following example associates the cluster with an NTP server named ntp1.example.com.
cluster time-service ntp server delete

Delete a NTP Server

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**

The `cluster time-service ntp server delete` command removes the association between the cluster and an external network time server that uses the Network Time Protocol (NTP).

**Parameters**

- `-server <text>` - NTP Server Host Name, IPv4 or IPv6 Address
  
  This specifies the host name or IP address of an existing external NTP server that the cluster will disassociate from.

**Examples**

The following example disassociates an NTP server named `ntp2.example.com` from the cluster:

```
cluster1::> cluster time-service ntp server delete -server ntp2.example.com
```

cluster time-service ntp server modify

Modify NTP Server Options

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**

The `cluster time-service ntp server modify` command modifies the configuration of an existing external network time server that uses the Network Time Protocol (NTP) for time correction and adjustment.

**Parameters**

- `-server <text>` - NTP Server Host Name, IPv4 or IPv6 Address
  
  This parameter specifies the host name or IP address of an existing external NTP server that is to be modified.

[`--version 3|4|auto`] - NTP Version for Server (default: auto)

  Use this parameter to optionally specify the NTP protocol version that should be used for communicating with the external NTP server. If the external NTP server does not support the specified protocol version, time exchange cannot take place.

  The supported values for this parameter include the following:

  - 3 - Use NTP protocol version 3, which is based on Internet Standard request for comments (RFC) #1305.
  - 4 - Use NTP protocol version 4, which is based on Internet Standard RFC #5905.
  - auto - Have Data ONTAP select the NTP protocol version.

  The default setting is auto.
[-is-preferred (true|false)] - Is Preferred NTP Server (default: false) (privilege: advanced)

Use this parameter to optionally specify whether the external NTP server is the primary time source for correcting and adjusting the cluster time. The responses from this source are used unless its time is outside the accepted selection range.

The default setting is false.

You use this parameter when a high quality radio (or GPS) based time server is being used with a set of non-radio based backup time servers.

This parameter is available only at the advanced privilege level and higher.

[-is-authentication-enabled (true|false)] - Is NTP Symmetric Key Authentication Enabled

Use this parameter to optionally disable NTP symmetric key authentication for communication with the specified time server. Using this parameter and selecting false disables the NTP symmetric key authentication and clears the key-id parameter for the specified server. This parameter is not required to enable NTP symmetric key authentication, but if specified as true the NTP symmetric authentication key must also be specified using the key-id parameter.

[-key-id <integer>] - NTP Symmetric Authentication Key ID

Use this parameter to optionally enable NTP symmetric authentication key for communication with the specified time server. The ID must refer to a key created by the cluster time-service ntp key create command and must be a key with the same ID and value as one configured on the specified time server.

Examples

The following example modifies the NTP version of an NTP server named ntp1.example.com. The NTP version is changed to 4.

```
cluster1::> cluster time-service ntp server modify -server ntp1.example.com -version 4
```

Related references

cluster time-service ntp key create on page 82

cluster time-service ntp server reset

Reset NTP server list to a default selection

Availability: This command is available to cluster administrators at the advanced privilege level.

Description

The cluster time-service ntp server reset command replaces the current configuration with one of the selected configurations.

If none or more than one time service configuration is selected, the command will fail.

Parameters

[-use-public (true|false)] - Reset Server List to Public Identified Defaults (default: false)

When set to true, this specifies that the public NTP server list used by Data ONTAP should replace the current configuration.

The default setting is false.

Examples

The following example replaces the current time service configuration with the default public NTP server list that is used by Data ONTAP.
cluster time-service ntp server show

Display a list of NTP Servers

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The cluster time-service ntp server show command displays the association between the cluster and external network time servers that use the Network Time Protocol (NTP).

Parameters
{-fields <fieldname>,...}
If you specify the -fields <fieldname>,... parameter, the command only displays the fields that you specify. For example: -fields server, version.

{-instance}
If this parameter is specified, the command displays all the available field information.

{-server <text> } - NTP Server Host Name, IPv4 or IPv6 Address
If this parameter is specified, the command displays the external NTP servers that match the specified server name or IP address.

{-version {3|4|auto}} - NTP Version for Server (default: auto)
If this parameter is specified, the command displays the external NTP servers that use the specified NTP version.

{-is-preferred {true|false}} - Is Preferred NTP Server (default: false) (privilege: advanced)
If this parameter is specified, the command displays the external NTP server or servers that match the specified preferred server status.

{-is-public {true|false}} - Is Public NTP Server Default (privilege: advanced)
If this parameter is specified, the command displays the information for the external NTP servers that are either on the NTP server list defined by Data ONTAP (true) or not on the list (false).

{-is-authentication-enabled {true|false}} - Is NTP Symmetric Key Authentication Enabled
If this parameter is specified, the command displays the external NTP server or servers that require NTP symmetric key authentication for communication.

{-key-id <integer>} - NTP Symmetric Authentication Key ID
If this parameter is specified, the command displays the external NTP server or servers that match the specified symmetric authentication key ID.

Examples
The following example displays information about all external NTP time servers that are associated with the cluster:

```
cluster1::> cluster time-service ntp server show
<table>
<thead>
<tr>
<th>Server</th>
<th>Version</th>
<th>Authentication Enabled</th>
<th>Key ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>ntp1.example.com</td>
<td>auto</td>
<td>false</td>
<td>-</td>
</tr>
<tr>
<td>ntp2.example.com</td>
<td>auto</td>
<td>true</td>
<td>10</td>
</tr>
</tbody>
</table>
```
**cluster time-service ntp status commands**

The status directory

---

**cluster time-service ntp status show**

Display status of the node’s NTP client

**Availability:** This command is available to cluster administrators at the advanced privilege level.

**Description**

The `cluster time-service ntp status show` command displays the status of the associations between the cluster and external network time servers that use the Network Time Protocol (NTP).

**Parameters**

```
[ [-fields <fieldname>, ...] ]
```

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

```
[ [ -instance ]] 
```

If this parameter is specified, the command displays detailed information about all entries.

```
[ -node <nodename> | local ] - Node
```

If this parameter is specified, the command displays information related to associations on the specified node.

```
[ -server <text> ] - NTP Server Host Name, IPv4 or IPv6 Address
```

If this parameter is specified, the command displays information about the associations related to the specified NTP server. The server should be specified as it is configured in the `cluster time-service ntp server show` command.

```
[ -server-address <IP Address> ] - Server IP Address
```

If this parameter is specified, the command displays information about the associations related to the NTP server with the specified IP address.

```
[ -is-peer-reachable {true|false} ] - Is Peer Reachable and Responding to Polls?
```

If this parameter is specified as `true`, the command displays information about associations with the NTP servers that have been successfully polled.

```
[ -is-peer-selected {true|false} ] - Is Peer Selected as Clock Source?
```

If this parameter is specified as `true`, the command displays information about associations with the NTP servers that have been selected as the current clock source.

```
```

If this parameter is specified, the command displays information about associations with the specified selection state.

```
[ -selection-state-text <text> ] - Description of Server Selection State
```

If this parameter is specified, the command displays information about associations with the specified selection state description.

```
[ -poll-interval <integer> ] - Poll Interval (secs)
```

If this parameter is specified, the command displays information about associations that have the specified polling interval.

```
[ -time-last-poll <integer> ] - Time from Last Poll (secs)
```

If this parameter is specified, the command displays information about associations that are polled at the specified time.
[-offset <double>] - Offset from Server Time (ms)
If this parameter is specified, the command displays information about associations with the specified offset from the NTP server.

[-delay <double>] - Delay Time to Server (ms)
If this parameter is specified, the command displays information about associations with the specified travelling time to the NTP server.

[-jitter <double>] - Maximum Offset Error (ms)
If this parameter is specified, the command displays information about associations with the specified offset error from the NTP server.

[-reachability <Hex String>] - Reachability of Server
If this parameter is specified, the command displays information about associations with the specified reachability to the NTP server. Reachability is specified as a hexbyte that has a bit to represent the success of each of the last eight polls of the specified server. A set bit represents a successful poll. The least significant bit represents the most recent poll, the next most significant bit the poll before that, and so on.

[-server-stratum <integer>] - Stratum of Server Clock
If this parameter is specified, the command displays information about associations with NTP servers with the specified clock stratum.

[-server-reference <text>] - Reference Clock at Server
If this parameter is specified, the command displays information about associations with NTP servers using the specified clock as reference.

[-reported-errors <NTP Peer and Packet Errors>, ...] - Reported Packet and Peer Errors
If this parameter is specified, the command displays information about associations with the specified errors.

Examples
The following example displays the status of the NTP associations of the cluster:

```
cluster-l-1:*>cluster time-service ntp status show
Node: node-1
<table>
<thead>
<tr>
<th>Server</th>
<th>Reachable</th>
<th>Selection State</th>
<th>Offset (ms)</th>
</tr>
</thead>
<tbody>
<tr>
<td>ntp1.eng.netapp.com</td>
<td>true</td>
<td>Currently Selected Server</td>
<td>39.122</td>
</tr>
<tr>
<td>ntp2.eng.netapp.com</td>
<td>true</td>
<td>Candidate Server</td>
<td>37.786</td>
</tr>
</tbody>
</table>
2 entries were displayed.
```

The following example displays the status of the association with the specified external NTP server:

```
cluster-l-1:*>cluster time-service ntp status show -instance -server ntp1.example.com
Node: node-1
NTP Server Host Name, IPv4 or IPv6 Address: ntp1.example.com
Server IP Address: 10.56.32.33
Is Peer Reachable and Responding to Polls?: true
Is Peer Selected as Clock Source?: true
State of Server Selection: sys_peer

```
Event Commands

Manage system events

The `event` commands enable you to work with system events and set up notifications.

**event catalog commands**

View the event catalog.

**event catalog show**

Display event definitions

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**

The `event catalog show` command displays information about events in the catalog. By default, this command displays the following information:

- Message name of the event
- Severity of the event
- SNMP trap type of the event

To display detailed information about a specific event, run the command with the `--message-name` parameter, and specify the name of the event. The detailed view adds the following information:

- Full description of the event
- Action to be taken to address the event
- Event's deprecation status

You can specify additional parameters to limit output to the information that matches those parameters. For example, to display information only about events with an event name that begins with `raid`, enter the command with the `--message-name raid*` parameter. The parameter value can either be a specific text string or a wildcard pattern.

Alternatively, an event filter can also be specified to limit the output events.

**Parameters**

```
[-fields <fieldname>, ...]
```

If you specify the `--fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `--fields ?` to display the fields to specify.

```
[-instance]
```

If you specify the `--instance` parameter, the command displays detailed information about all fields.

```
[--message-name <Message Name>] - Message Name
```

Selects the events that match this parameter value.
### [-filter-name <text>] - Filter Name

Selects the events that match this parameter value. The parameter value indicates an existing filter name that, when applied permits the inclusion of the listed events.

### [-severity {EMERGENCY|ALERT|ERROR|NOTICE|INFORMATIONAL|DEBUG}] - Severity

Selects the events that match this parameter value.

### [-description <text>] - Description

Selects the events that match this parameter value.

### [-action <text>] - Corrective Action

Selects the events that match this parameter value.

### [-snmp-trap-type {Standard|Built-in|Severity-based}] - SNMP Trap Type

Selects the events that match this parameter value. The parameter value describes the type of SNMP trap associated with the event. The value can be one of the following: Standard trap type events are those defined in the RFCs. Built-in trap types are those that are NetApp Enterprise traps specific to events. The remaining events are considered to have Severity-based SNMP trap types.

### [-deprecated {true|false}] - Is Deprecated

Selects the events that match this parameter value. The parameter value indicates whether the event is deprecated or not.

**Note:** Deprecated events may be removed in a future release of Data ONTAP.

### Examples

The following example displays the event catalog:

```
cluster1::> event filter show -filter-name filter1
Filter Name Rule     Rule      Message Name           SNMP Trap Type  Severity
----------- -------- --------- ---------------------- --------------- --------
filter1     1        include   zapi.*                 *               *
2 entries were displayed.

cluster1::> event catalog show -filter-name filter1
Message                          Severity         SNMP Trap Type
-------------------------------- ---------------- -----------------
zapi.killed                      NOTICE           Severity-based
zapi.method.notfound             NOTICE           Severity-based
zapi.sf.up.ready                 INFORMATIONAL  Severity-based
zapi.snapshot.success            NOTICE           Severity-based
zapi.streamout.noMethod          NOTICE           Severity-based
5 entries were displayed.

cluster1::> event catalog show -message-name zsm.* -filter-name filter1
There are no entries matching your query.

cluster1::> event catalog show -message-name zapi.* -filter-name filter1
Message                          Severity         SNMP Trap Type
-------------------------------- ---------------- -----------------
zapi.method.notfound             NOTICE           Severity-based
zapi.sf.up.ready                 INFORMATIONAL  Severity-based
zapi.snapshot.success            NOTICE           Severity-based
zapi.streamout.noMethod          NOTICE           Severity-based
4 entries were displayed.

cluster1::> event catalog show -message-name CR.*
Message                          Severity         SNMP Trap Type
-------------------------------- ---------------- -----------------
CR.Corrupt.Redir.Deleted         INFORMATIONAL  Severity-based
CR.Dangling.Redir.Deleted        INFORMATIONAL  Severity-based
CR.Data.File.Inaccessible       NOTICE           Severity-based
CR.Del.CrptStreamData.Fail      NOTICE           Severity-based
4 entries were displayed.
```

### event catalog commands

93
event filter commands

Create, delete and view event filters.

event filter copy

Copy an event filter

Availability: This command is available to \textit{cluster} administrators at the \textit{admin} privilege level.

Description
The event filter copy command copies an existing filter to a new filter. The new filter will be created with rules from the source filter. For more information, see the event filter create command.

Parameters

\texttt{-filter-name <text> - Filter Name}

Use this mandatory parameter to specify the name of the event filter to copy.

\texttt{-new-filter-name <text> - New Event Filter Name}

Use this mandatory parameter to specify the name of the new event filter to create and copy the rules.
Examples

The following example copies an existing event filter named emer-wafl-events to a new filter named filter1:

```
cluster1::> event filter show
Filter Name    Rule     Rule      Message Name           SNMP Trap Type  Severity
Position Type  ----------- -------- --------- ---------------------- --------------- --------
default-trap-events
1    include   *                      *               EMERGENCY, ALERT
2    include   *                      Standard, Built-in
3    exclude   *                      *
emer-wafl-events
1    include   wafl.*                 *               EMERGENCY
2    exclude   *                      *
important-events
1    include   *                      *               EMERGENCY, ALERT
2    include   callhome.*             *               ERROR
3    exclude   *                      *
no-info-debug-events
1    include   *                      EMERGENCY, ALERT, ERROR,
NOTICE
2    exclude   *                      *
10 entries were displayed.
```

```
cluster1::> event filter copy -filter-name emer-wafl-events -new-filter-name filter1
cluster1::> event filter show
Filter Name    Rule     Rule      Message Name           SNMP Trap Type  Severity
Position Type  ----------- -------- --------- ---------------------- --------------- --------
default-trap-events
1    include   *                      *               EMERGENCY, ALERT
2    include   *                      Standard, Built-in
3    exclude   *                      *
emer-wafl-events
1    include   wafl.*                 *               EMERGENCY
2    exclude   *                      
filter1
1    include   wafl.*                 *               EMERGENCY
2    exclude   *                      
important-events
1    include   *                      *               EMERGENCY, ALERT
2    include   callhome.*             *               ERROR
3    exclude   *                      *
no-info-debug-events
1    include   *                      EMERGENCY, ALERT, ERROR,
NOTICE
2    exclude   *                      
12 entries were displayed.
```

*event filter create* on page 95

event filter create

Create a new event filter.

**Availability:** This command is available to cluster administrators at the *admin* privilege level.
The event filter create command creates a new event filter. An event filter is used to select the events of interest and is made up of one or more rules, each of which contains the following three fields:

- name - event (message) name.
- severity - event severity.
- snmp-trap-type - event SNMP trap type.

These fields are evaluated for a match using a logical "AND" operation: name AND severity AND SNMP trap type. Within a field, the specified values are evaluated with an implicit logical "OR" operation. So, if `-snmp-trap-type Standard, Built-in` is specified, then the event must match Standard OR Built-in. The wildcard matches all values for the field.

- Type - include or exclude. When an event matches an include rule, it will be included into the filter, whereas it will be excluded from the filter if it matches an exclude rule.

Rules are checked in the order they are listed for a filter, until a match is found. There is an implicit rule at the end that matches every event to be excluded. For more information, see the `event filter rule` command.

There are three system-defined event filters provided for your use:

- default-trap-events - This filter matches all ALERT and EMERGENCY events. It also matches all Standard, Built-in SNMP trap type events.
- important-events - This filter matches all ALERT and EMERGENCY events.
- no-info-debug-events - This filter matches all non-INFO and non-DEBUG messages (EMERGENCY, ALERT, ERROR and NOTICE).

The system-defined event filters cannot be modified or deleted.

Parameters

- **-filter-name <text>** - Filter Name

  Use this mandatory parameter to specify the name of the event filter to create. An event filter name is 2 to 64 characters long. Valid characters are the following ASCII characters: A-Z, a-z, 0-9, ".", and "_". The name must start and end with: A-Z, a-z, ".", or 0-9.

Examples

The following example creates an event filter named filter1:

```
cluster1::> event filter create -filter-name filter1
```

```
cluster1::> event filter show
Filter Name  Rule      Rule      Message Name           SNMP Trap Type  Severity
----------- -------- --------- ---------------------- --------------- --------
default-trap-events
1        include   *                      *               EMERGENCY, ALERT
2        include   *                      Standard, Built-in
3        exclude   *                      *               *
filter1
1        exclude   *                      *               *
important-events
1        include   *                      *               EMERGENCY, ALERT
2        include   callhome.*             *               ERROR
3        exclude   *                      *               *
no-info-debug-events
```

`event filter rule` on page 102

**event filter delete**

Delete existing event filters

**Availability:** This command is available to `cluster` administrators at the `admin` privilege level.

**Description**

The `event filter delete` command deletes an existing event filter, along with all its rules.

The system-defined event filters cannot be deleted.

For more information, see the `event filter create` command.

**Parameters**

- `-filter-name <text>` - Filter Name

  Use this mandatory parameter to specify the name of the event filter to delete.

**Examples**

The following example deletes an event filter named `filter1`:

```
cluster1::> event filter show
Filter Name    Rule    Rule    Message Name    SNMP Trap Type  Severity
--------------- -------- --------- ---------------------- --------------- --------
default-trap-events
1  include    *        *        EMERGENCY, ALERT
2  include    *        Standard, Built-in
3  exclude    *        *

filter1
1  include    wafl.*    *        EMERGENCY
2  exclude    *        *

important-events
1  include    *        *        EMERGENCY, ALERT
2  include    callhome.*    *        ERROR
3  exclude    *        *

ox-info-debug-events
1  include    *        *        EMERGENCY, ALERT, ERROR,
2  exclude    *        *

10 entries were displayed.
```

```
cluster1::> event filter delete -filter-name filter1
```

```
cluster1::> event filter show
Filter Name    Rule    Rule    Message Name    SNMP Trap Type  Severity
--------------- -------- --------- ---------------------- --------------- --------
default-trap-events
1  include    *        *        EMERGENCY, ALERT
2  include    *        Standard, Built-in
3  exclude    *        *

important-events
1  include    *        *        EMERGENCY, ALERT
2  include    callhome.*    *        ERROR
3  exclude    *        *
```

**event filter delete**

Delete existing event filters

**Availability:** This command is available to `cluster` administrators at the `admin` privilege level.

**Description**

The `event filter delete` command deletes an existing event filter, along with all its rules.

The system-defined event filters cannot be deleted.

For more information, see the `event filter create` command.

**Parameters**

- `-filter-name <text>` - Filter Name

  Use this mandatory parameter to specify the name of the event filter to delete.

**Examples**

The following example deletes an event filter named `filter1`:

```
cluster1::> event filter show
Filter Name    Rule    Rule    Message Name    SNMP Trap Type  Severity
--------------- -------- --------- ---------------------- --------------- --------
default-trap-events
1  include    *        *        EMERGENCY, ALERT
2  include    *        Standard, Built-in
3  exclude    *        *

filter1
1  include    wafl.*    *        EMERGENCY
2  exclude    *        *

important-events
1  include    *        *        EMERGENCY, ALERT
2  include    callhome.*    *        ERROR
3  exclude    *        *

no-info-debug-events
1  include    *        *        EMERGENCY, ALERT, ERROR,
2  exclude    *        *

10 entries were displayed.
```

```
cluster1::> event filter delete -filter-name filter1
```

```
cluster1::> event filter show
Filter Name    Rule    Rule    Message Name    SNMP Trap Type  Severity
--------------- -------- --------- ---------------------- --------------- --------
default-trap-events
1  include    *        *        EMERGENCY, ALERT
2  include    *        Standard, Built-in
3  exclude    *        *

important-events
1  include    *        *        EMERGENCY, ALERT
2  include    callhome.*    *        ERROR
3  exclude    *        *
```

event filter commands
event filter rename

Rename an event filter

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The event filter rename command is used to rename an existing event filter. There are system-defined event filters provided for your use. The system-defined event filters cannot be modified or deleted. For more information, see the event filter create command.

Parameters
-filt
- Filter Name
Use this mandatory parameter to specify the name of the event filter to rename.

-nf
- New Event Filter Name
Use this mandatory parameter to specify the new name the event filter should be renamed to.

Examples
The following example renames an existing filter named filter1 as emer-wafl-events:

```
cluster1::> event filter show
Filter Name Rule Position Message Name SNMP Trap Type Severity
----------- -------- --------- ---------------------- --------------- --------
default-trap-events 1 include * Standard, Built-in *
2 include * * *
3 exclude * * *
filter1 1 include wafl.* * *
2 exclude * * *
important-events 1 include * * EMERGENCY, ALERT
2 include callhome.* * ERROR
3 exclude * * *
no-info-debug-events 1 include * EMERGENCY, ALERT, ERROR,
NOTICE 2 exclude * * *
10 entries were displayed.
cluster1::> event filter rename -filter-name filter1 -new-filter-name emer-wafl-events
```

```
cluster1::> event filter show
Filter Name Rule Position Message Name SNMP Trap Type Severity
----------- -------- --------- ---------------------- --------------- --------
default-trap-events 1 include * Standard, Built-in *
2 include * * *
3 exclude * * *
emer-wafl-events
```

Related references
event filter create on page 95

Parameters:

-filt-name <text> - Filter Name
Use this mandatory parameter to specify the name of the event filter to rename.

-nf-name <text> - New Event Filter Name
Use this mandatory parameter to specify the new name the event filter should be renamed to.

### event filter show

Display the list of existing event filters.

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**

The *event filter show* command displays all the event filters which are configured. An event filter is used to select the events of interest and is made up of one or more rules, each of which contains the following three fields:

- **name** - event (message) name.
- **severity** - event severity.
- **snmp-trap-type** - event SNMP trap type.

These fields are evaluated for a match using a logical "AND" operation: name AND severity AND SNMP trap type. Within a field, the specified values are evaluated with an implicit logical "OR" operation. So, if `-snmp-trap-type Standard, Built-in` is specified, then the event must match *Standard* OR *Built-in*. The wildcard matches all values for the field.

- **Type** - include or exclude. When an event matches an include rule, it will be included into the filter, whereas it will be excluded from the filter if it matches an exclude rule.

Rules are checked in the order they are listed for a filter, until a match is found. There is an implicit rule at the end that matches every event to be excluded. For more information, see *event filter rule* command.

There are three system-defined event filters provided for your use:

- **default-trap-events** - This filter matches all ALERT and EMERGENCY events. It also matches all Standard, Built-in SNMP trap type events.
- **important-events** - This filter matches all ALERT and EMERGENCY events.
- **no-info-debug-events** - This filter matches all non-INFO and non-DEBUG messages (EMERGENCY, ALERT, ERROR and NOTICE).

The system-defined event filters cannot be modified or deleted.

**Parameters**

```
[[-fields <fieldname>, ...]
    If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.
]

[[-instance]]
    If you specify the `-instance` parameter, the command displays detailed information about all fields.
```
[-filter-name <text>] - Filter Name
Selects the event filters that match this parameter value.

[-position <integer>] - Rule Position
Selects the event filters that match this parameter value.

[-type {include|exclude}] - Rule Type
Selects the event filters that match this parameter value. The rule types are as follows:
• include - Events matching this rule are included in the specified filter.
• exclude - Events matching this rule are excluded in the specified filter.

[-message-name <text>] - Message Name
Selects the event filters that match this parameter value.

[-severity <text>,...] - Severity
Selects the events that match this parameter value. Severity levels:
• EMERGENCY - Disruption.
• ALERT - Single point of failure.
• ERROR - Degradation.
• NOTICE - Information.
• INFORMATIONAL - Information.
• DEBUG - Debug information.
• * - Includes all severities.

[-snmp-trap-type <text>,...] - SNMP Trap Type
Selects the event filters that match this parameter value. The SNMP trap types are as follows:
• Standard - Traps defined in RFCs.
• Built-in - Enterprise traps specific to events.
• Severity-based - Traps specific to events that do not belong to the above two types.
• * - Includes all SNMP trap types.

Examples
The following example displays the event filters:

```
cluster1:/> event filter show
Filter Name  Rule     Rule Type Message Name          SNMP Trap Type  Severity
----------- ------- --------- ---------------------- --------------- --------
default-trap-events 1        include   *                      *               EMERGENCY, ALERT
   2        include   *                      Standard, Built-in
   3        exclude   *                      *               *
important-events    1        include   *                      *               EMERGENCY, ALERT
   2        exclude   *                      *               *
no-info-debug-events 100
```
The following example displays the event filters queried on the SNMP trap type value "Standard":

```
cluster1::> event filter show -snmp-trap-type Standard
Filter Name       Rule   Rule   Message Name              SNMP Trap Type  Severity
Position Type
----------- ------- --------- ---------------------- --------------- --------
default-trap-events 2    include  *                      Standard, Built-in
```

The following example displays the event filters with one or more rules that have no condition on the SNMP trap type. Note that the wildcard character has to be specified in double-quotes. Without double-quotes, output would be the same as not querying on the field.

```
cluster1::> event filter show -snmp-trap-type "*"
Filter Name       Rule   Rule   Message Name              SNMP Trap Type  Severity
Position Type
----------- ------- --------- ---------------------- --------------- --------
default-trap-events 1    include  *                      EMERGENCY, ALERT
                  3    exclude   *                      *
important-events 1    include  *                      EMERGENCY, ALERT
no-info-debug-events 2    exclude   *                      *
NOTICE             2    exclude   *                      *
```

**event filter test**

Test an event filter

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**

The event filter test command is used to test an event filter. When specified with a message name, the command displays whether the message name is included or excluded from the filter. When specified without a message name, the command displays the number of events from the catalog that match the filter. For more information, see the event filter create command.

**Parameters**

- `-filter-name <text>` - Filter Name
  
  Use this mandatory parameter to specify the name of the event filter to test.

- `[-message-name <Message Name>]` - Message Name
  
  Use this optional parameter to specify the message name of the event to test against the filter.

**Examples**

The following example tests an event filter named err-waf1-no-scan-but-clone:

event filter rule commands

Create and delete rules for a filter.

event filter rule add

Add a rule for an event filter

Availability: This command is available to *cluster* administrators at the *admin* privilege level.

Description

The *event filter rule add* command adds a new rule to an existing event filter. See *event filter create* for more information on event filters and how to create a new event filter.

Parameters

*--filter-name <text>* - Filter Name

Use this mandatory parameter to specify the name of the event filter to add the rule. Rules cannot be added to system-defined event filters.
[-position <integer>] - Rule Position
Use this optional parameter to specify the position of the rule in the event filter. It should be in the range (1..n-1), where 'n' is the position of the last rule, which is an implicit rule. Rules are checked in the order they are listed for a filter, until a match is found.

-type {include|exclude} - Rule Type
Use this mandatory parameter to specify the type of the rule which determines whether to include or exclude the events that match this rule.

[-message-name <text>] - Message Name
Use this parameter to specify the message name of the event to include or exclude from the filter.

[-severity <text>,...]- Severity
Use this parameter to specify the list of severity values to match against the events. Enter multiple severities separated by a comma. To enter all severities, the wild card (*) can be used. The wild card cannot be specified with other severities. The default value is *.

[-snmp-trap-type <text>,...] - SNMP Trap Type
Use this parameter to specify the list of the SNMP trap type values to match against the events. Enter multiple SNMP trap types separated by comma. To enter all SNMP trap types, the wild card (*) can be used. The wild card cannot be specified with other SNMP trap types. The default value is *.

Example
The following example adds a rule to an existing event filter "emer-and-wafl": All events with severity EMERGENCY and message name starting with "wafl.*" are included in the filter. Not specifying the SNMP trap type implies a default value of "*".

```
cluster1::> event filter rule add -filter-name emer-and-wafl -type include -message-name wafl.* -severity EMERGENCY
cluster1::> event filter show
Filter Name Rule     Rule      Message Name           SNMP Trap Type  Severity
----------- -------- --------- ---------------------- --------------- --------
default-trap-events
1        include   *                      *               EMERGENCY, ALERT
2        include   *                      Standard, Built-in
3        exclude   *                      *               *
emer-and-wafl
1        include   wafl.*                 *               EMERGENCY
2        exclude   *                      *               *
important-events
1        include   *                      *               EMERGENCY, ALERT
2        include   callhome.*             *               ERROR
3        exclude   *                      *               *
no-info-debug-events
1        include   *                      *               EMERGENCY, ALERT, ERROR,
NOTICE
2        exclude   *                      *               *
10 entries were displayed.
```

The following example adds a rule to the event filter "emer-and-wafl" at position 1: All events with severity ALERT and message name starting with "wafl.scan.*" are included in the filter.

```
cluster1::> event filter rule add -filter-name emer-and-wafl -type include -message-name wafl.scan.* -position 1 -severity ALERT
cluster1::> event filter show
Filter Name Rule     Rule      Message Name           SNMP Trap Type  Severity
----------- -------- --------- ---------------------- --------------- --------
default-trap-events
1        include   *                      *               EMERGENCY, ALERT
2        include   *                      Standard, Built-in
```
The following example adds a rule to the event filter "emer-and-waf1" to include all "Standard" SNMP trap type events:

```
cluster1::> event filter rule add -filter-name emer-and-waf1 -type include -snmp-trap-type Standard
```

The event filter rules are as follows:

<table>
<thead>
<tr>
<th>Filter Name</th>
<th>Rule</th>
<th>Message Name</th>
<th>SNMP Trap Type</th>
<th>Severity</th>
</tr>
</thead>
<tbody>
<tr>
<td>default-trap-events</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>emer-and-waf1</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>important-events</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>no-info-debug-events</td>

*event filter create* on page 95

**event filter rule delete**

Delete a rule for an event filter

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**

The *event filter rule delete* command deletes a rule from an event filter. The position of all the rules following the deleted rule is updated to maintain a contiguous sequence. Use *event filter show* command to view the filters and the rules associated with them.

**Parameters**

*--filter-name <text>* - Filter Name

Use this mandatory parameter to specify the name of the event filter from which you want to delete the rule. Rules cannot be deleted from system-defined filters.
-position <integer> - Rule Position

Use this mandatory parameter to specify the position of the rule to delete from the filter. It should be in the range (1..n-1), where ‘n’ is the position of the last rule, which is an implicit rule.

Examples

The following example deletes a rule at position 2 from an existing event filter "emer-and-waf1":

```
cluster1::> event filter show
Filter Name    Rule      Message Name           SNMP Trap Type  Severity
Position Type
----------- -------- ---------------------- --------------- -------
default-trap-events
1        include   *                      *               EMERGENCY, ALERT
2        include   *                      Standard, Built-in
3        exclude   *                      *               *
emer-and-waf1
1        include   waf1.scan.*            *               ALERT
2        include   waf1.*                 *               EMERGENCY
3        include   *                      Standard        *
4        exclude   *                      *               *
important-events
1        include   *                      *               EMERGENCY, ALERT
2        include   callhome.*             *               ERROR
3        exclude   *                      *               *
no-info-debug-events
1        include   *                      *               EMERGENCY, ALERT, ERROR,
NOTICE
2        exclude   *                      *               *
12 entries were displayed.

event filter rule reorder

Modify the index of a rule for an event filter

Availability: This command is available to cluster administrators at the admin privilege level.
Description
The event filter rule reorder command moves a rule to a new position in an existing event filter. Use event filter show command to display all the event filters and the rules associated with them.

Parameters
- **-filter-name <text>** - Filter Name
  Use this mandatory parameter to specify the name of the event filter from which you want to change the position of the rule. Rules from system-defined event filters cannot be modified.

- **-position <integer>** - Rule Position
  Use this mandatory parameter to specify the position of the rule you want to change. It should be in the range (1..n-1), where ‘n’ is the position of the last rule, which is an implicit rule.

- **-to-position <integer>** - New Rule Position
  Use this mandatory parameter to specify the new position to move the rule. It should be in the range (1..n-1), where ‘n’ is the position of the last rule, which is an implicit rule.

Examples
The following example changes the position of a rule from 1 to 2 from an existing event filter "emer-and-wafl":

```
cluster1::> event filter show
Filter Name Rule Position Type Message Name           SNMP Trap Type  Severity
----------- -------- --------- ---------------------- --------------- --------
default-trap-events 1        include   *                      *               EMERGENCY, ALERT
2        include   *                      Standard, Built-in
3        exclude   *                      *               *
emer-and-wafl 1        include   wafl.scan.*            *               ALERT
2        include   *                      Standard        *
3        exclude   *                      *               *
important-events 1        include   *                      *               EMERGENCY, ALERT
2        include   callhome.*             *               ERROR
3        exclude   *                      *               *
no-info-debug-events 1        include   *                      *               EMERGENCY, ALERT, ERROR,
2        exclude   *                      NOTICE
11 entries were displayed.
cluster1::> event filter rule reorder -filter-name emer-and-wafl -position 1 -to-position 2
cluster1::> event filter show
Filter Name Rule Position Type Message Name           SNMP Trap Type  Severity
----------- -------- --------- ---------------------- --------------- --------
default-trap-events 1        include   *                      *               EMERGENCY, ALERT
2        include   *                      Standard, Built-in
3        exclude   *                      *               *
emer-and-wafl 1        include   wafl.scan.*            *               ALERT
2        include   *                      Standard        *
3        exclude   *                      *               *
important-events 1        include   *                      *               EMERGENCY, ALERT
2        include   callhome.*             *               ERROR
3        exclude   *                      NOTICE
11 entries were displayed.

*event filter show* on page 99

**event config commands**

Configure the mail server settings used for notifications

**event config force-sync**

Synchronize a node's EMS configuration with the cluster wide EMS configuration

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

**Description**

The *event config force-sync* command forces a node's EMS configuration to be synchronized with the cluster wide EMS configuration. The configuration is automatically synchronized among all nodes in the cluster, but in rare cases a node may not be updated. This command simplifies the recovery from this issue.

The following example shows where this command is useful: An email destination is configured for all CRITICAL level event occurrences. When the event is generated, all nodes generate an email except one. This command forces that node to refresh a stale configuration.

**Parameters**

[-node {<nodename>|local}] - Node

The node parameter specifies which controller will be synchronized.

**event config modify**

Modify log configuration parameters

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**

Use the *event config modify* command to configure event notification and logging for the cluster.

**Parameters**

[-mail-from <mail address>] - Mail From

Use this parameter to configure the email address from which email notifications will be sent. You can configure the cluster to send email notifications when specific events occur. Use the *event route add-destinations* and *event destination create* commands to configure email destinations for events.

[-mail-server <text>] - Mail Server (SMTP)

Use this parameter to configure the name or IP address of the SMTP server used by the cluster when sending email notification of events.

[-suppression {on|off}] - Event Throttling/Suppression (privilege: advanced)

Use this parameter to configure whether event suppression algorithms are enabled ("on") or disabled ("off"). The event processing system implements several algorithms to throttle events. The documentation for *event show-suppression* command describes the suppression algorithms in detail.

**Note:** The suppression parameter can disable both autosuppression and duplicate suppression, but timer suppression cannot be disabled.
[console {on|off}] - Console Logging (privilege: advanced)

Use this parameter to configure whether events are displayed on the console port ("on") or not displayed("off").

[proxy-url <text>] - HTTP/HTTPS Proxy URL

If your organization uses a proxy, use this parameter to specify an HTTP or HTTPS proxy for rest-api type EMS notification destinations. The URL must start with an http:// prefix. HTTPS connections to a proxy are not supported. To specify a URL that contains a question mark, press ESC followed by the ".?".

[proxy-user <text>] - User Name for HTTP/HTTPS Proxy

If authentication is required, use this parameter to specify the user name for the HTTP or HTTPS proxy server specified by the -proxy-url parameter. Use the event config set-proxy-password command to set the password used for this user name.

Examples

The following command sets the "Mail From" address for event notifications to "admin@example.com" and the "Mail Server" to "mail.example.com":

```
cluster1::> event config modify -mailfrom admin@example.com -mailserver mail.example.com
```

The following command configures a proxy that requires authentication:

```
cluster1::> event config modify -proxy-url http://proxy.example.com:8080 -proxy-user-name admin
cluster1::> event config set-proxy-password
```

Enter the password:
Enter the password:

The following example turns on event suppression and console logging:

```
cluster1::> event config modify -suppression on -console on
```

- event destination create on page 110
- event log show on page 116
- event config set-proxy-password on page 108

event config set-proxy-password

Modify password for proxy server

Availability: This command is available to cluster administrators at the admin privilege level.

Description

Use the event config set-proxy-password command to set the password for authenticated access to an HTTP or HTTPS proxy being used for EMS notifications. This password is used with the user name you specify using the event config modify -proxy-user command to send EMS messages to REST API destinations via the proxy you specify using the event config modify -proxy-url command. If you enter the command without parameters, the command prompts you for a password and for a confirmation of that password. Enter the same password at both prompts. The password is not displayed.

Examples

The following example shows successful execution of this command:
event config show

Display log configuration parameters

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The event config show command displays information about the configuration of event notification and event logging for the cluster.

"Mail From" is the email address that the event notification system uses as the "From" address for email notifications.
"Mail Server" is the name or IP address of the SMTP server that the event notification system uses to send email notification of events.
"Proxy URL" is the HTTP or HTTPS proxy server URL used by rest-api type EMS notification destinations if your organization uses a proxy.
"Proxy User Name" is the user name for the HTTP or HTTPS proxy server if authentication is required.
"Suppression" indicates whether event suppression algorithms are enabled ("on") or disabled ("off"). The event processing system implements several algorithms to throttle events.

Note: The suppression parameter can disable both autosuppression and duplicate suppression, but not timer suppression.

"Console" indicates whether events are displayed on the console port ("on") or not displayed("off").

Examples
The following example displays the configuration of event notification for the cluster:

```
cluster1::> event config show
            Mail From:  admin@example.com
            Mail Server:  mail.example.com
            Proxy URL:  -
            Proxy User Name:  -
```

The following example displays the configuration of event notification with HTTP or HTTPS proxy:

```
cluster1::> event config show
            Mail From:  admin@example.com
            Mail Server:  mail.example.com
            Proxy URL:  http://proxy.example.com:3128
            Proxy User Name:  admin
```

At the diagnostic level, the output displays the following information:

```
cluster1::*> event config show
            Mail From:  admin@example.com
            Mail Server:  mail.example.com
            Suppression:  on
            Console:  on
            Max Target Log Size:  5242880
            Max Filter Count:  50
            Max Filter Rule Count:  128
            Max Destination Count:  20
```
event destination commands

(DEPRECATED)-Manage route destinations, for example e-mail or snmp

event destination create

(DEPRECATED)-Create an event destination

Availability: This command is available to cluster administrators at the admin privilege level.

Description

Note: This command has been deprecated. It may be removed from a future release of Data ONTAP. Instead, use the "event notification destination" command set.

The event destination create command creates a new event destination. An event destination is a list of addresses that receive event notifications. These addresses can be e-mail addresses, SNMP trap hosts, and syslog servers. Event destinations are used by event routes. Event routes describe which events generate notifications, and event destinations describe where to send those notifications.

When you create a destination, you can add e-mail addresses, SNMP trap hosts, and syslog hosts to the definition of the destination. Once the destination is fully defined, use the event route add-destinations command to associate the destination with event routes so that notifications of those events are sent to the recipients in the destination.

To see the current list of all destinations and their recipients, use the event destination show command.

There are several default destinations provided for your use.

- allevents - A useful destination for all system events, though no events are routed to this destination by default.
- asup - Events routed to this destination trigger AutoSupport(tm). Only use this destination to send notifications to technical support. See system node autosupport for more information.
- criticals - A useful destination for critical events though no events are routed to this destination by default.
- pager - A useful destination for all events that are urgent enough to page a system administrator, though no events are routed to this destination by default.
- traphost - The default destination for all SNMP traps. You can also use the system snmp traphost add command to add SNMP recipients to the traphost default destination.

To add recipients to the default destinations, use the event destination modify command.

You should not create a destination that sends events to more than one type of recipient. Use separate destinations for e-mail, SNMP, and syslog activity. Also, use the traphost default destination for all SNMP activity. You must not create any other destination that sends traps to SNMP trap hosts. The traphost default destination is not required to be added to any event route.

Parameters

-name <text> - Name

This mandatory parameter specifies name of the event destination to create.
[-mail <mail address>, ...] - Mail Destination

Use this parameter to specify one or more e-mail addresses to which event notifications will be sent. For events to properly generate e-mail notifications, the event system must also be configured with an address and mail server from which to send mail. See event config modify for more information.

[-snmp <Remote IP>, ...] - SNMP Destination

To send traps to SNMP trap hosts, use this parameter with the host names or IP addresses of those trap hosts.

[-syslog <Remote IP>, ...] - Syslog Destination

Use this parameter with the host names or IP addresses of any remote syslog daemons to which syslog entries will be sent.

[-syslog-facility <Syslog Facility>] - Syslog Facility

This parameter optionally specifies a syslog facility with which the syslog is sent. Possible values for this parameter are default, local0, local1, local2, local3, local4, local5, local6, and local7. If you specify the default syslog facility, syslogs are tagged LOG_KERN or LOG_USER.

[-snmp-community <text>] - SNMP Trap Community

To specify an SNMP trap community, use this parameter with that string.

[-hide-parameters (true|false)] - Hide Parameter Values?

Use this parameter with the value "true" to hide event parameters by removing them from event notifications. This is useful to prevent sensitive information from being sent over non-secure channels.

**Examples**

The following example creates an event destination named support.email that e-mails events to the addresses supportmgr@example.com, techsupport@example.com, and oncall@example.com.

```
cluster1::> event destination create -name support.email -mail supportmgr@example.com,techsupport@example.com,oncall@example.com
```

This example creates an event destination named support.bucket01 that sends the notifications to a syslog host.

```
cluster1::> event destination create -name support.bucket01 -syslog loghost.example.com
```

**event destination delete**

(DEPRECATED)-Delete an event destination

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**

**Note:** This command has been deprecated. It may be removed from a future release of Data ONTAP. Instead, use the "event notification destination" command set.
The `event destination delete` command removes a specified destination from the list of valid destinations. An event destination is a list of addresses that receive event notifications. These addresses can be e-mail addresses, SNMP trap hosts, and syslog servers. Event destinations are used by event routes. Event routes describe which events generate notifications, and event destinations describe where to send those notifications.

Once you delete a destination, you will not be able to add that destination to any event route.

You will not be able to delete a destination if it is in use by any event routes. To remove a destination from all event routes, so that you can delete it, use the `event route remove-destinations -messagename * -destination name` command.

There are several default destinations that cannot be deleted:

- **allevents** - A useful destination for all system events, though no events are routed to this destination by default.
- **asup** - Events routed to this destination trigger AutoSupport(tm). Only use this destination to send notifications to technical support. See `system node autosupport` for more information.
- **criticals** - A useful destination for critical events though no events are routed to this destination by default.
- **pager** - A useful destination for all events that are urgent enough to page a system administrator, though no events are routed to this destination by default.
- **traphost** - The default destination for all SNMP traps. You can also use the `system snmp traphost delete` command to delete SNMP recipients from the traphost default destination.

To see the current list of all destinations, use the `event destination show` command. To add a new destination to the list, use the `event destination create` command.

**Parameters**

- **-name <text>** - Name
  
  This mandatory parameter specifies the event destination to delete.

**Examples**

The following example deletes an event destination named manager.pager:

```
cluster1::> event destination delete -name manager.pager
```

**Related references**

- `event route remove-destinations` on page 133
- `system node autosupport` on page 1279
- `system snmp traphost delete` on page 1437
- `event destination show` on page 114
- `event destination create` on page 110

**event destination modify**

(DEPRECATED)-Modify an event destination

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**

- **Note:** This command has been deprecated. It may be removed from a future release of Data ONTAP. Instead, use the "event notification destination" command set.

The `event destination modify` command changes the definition of an existing event destination. An event destination is a list of addresses that receive event notifications. These addresses can be e-mail addresses, SNMP trap hosts, and syslog servers.
Event destinations are used by event routes. Event routes describe which events generate notifications, and event destinations describe where to send those notifications.

Modifying a parameter writes over the existing value of the parameter. To extend a parameter, make sure to include the current value of that parameter. For instance, to add an e-mail address to a destination, include all of the current e-mail addresses assigned to that destination along with the new address. To see the current definition of a destination, use the `event destination show -name name` command.

You must not create a destination that sends events to more than one type of recipient. Use separate destinations for e-mail, SNMP, and syslog activity. Also, use the traphost default destination for all SNMP activity. You should not create any other destination that sends to SNMP traphosts. The traphost default destination is not required to be added to any event route.

### Parameters

**-name <text>** - Name

This mandatory parameter specifies name of the event destination to modify.

**[-mail <mail address>,...]** - Mail Destination

Use this parameter to specify one or more e-mail addresses to which event notifications will be sent. For events to properly generate e-mail notifications, the event system must also be configured with an address and mail server from which to send mail. See `event config modify` for more information.

**[-snmp <Remote IP>,...]** - SNMP Destination

To send traps to SNMP trap hosts, use this parameter with the host names or IP addresses of those trap hosts.

**[-syslog <Remote IP>,...]** - Syslog Destination

Use this parameter with the host names or IP addresses of any remote syslog daemons to which syslog entries will be sent.

**[-syslog-facility <Syslog Facility>]** - Syslog Facility

This parameter optionally specifies a syslog facility with which the syslog is sent. Possible values for this parameter are default, local0, local1, local2, local3, local4, local5, local6, and local7. If you specify the default syslog facility, sylogs are tagged LOG_KERN or LOG_USER.

**[-snmp-community <text>]** - SNMP Trap Community

To specify an SNMP trap community, use this parameter with that string.

**[-hide-parameters {true|false}]** - Hide Parameter Values?

Enter this parameter with the value "true" to hide event parameters by removing them from event notifications. This is useful to prevent sensitive information from being sent over non-secure channels. Enter it with the value "false" to turn off parameter hiding.

### Examples

The following example modifies an event destination named snmp.hosts to send events to SNMP trap hosts named traphost1 and traphost2:

```
cluster1::> event destination modify -name snmp.hosts -snmp traphost1.example.com,traphost2.example.com
```

This example adds the e-mail address of a remote support facility to an existing list of e-mail recipients.

```
cluster1::> event destination show -name support

Name: support
  Mail Destination: support.hq@company.com
  SNMP Destination: -
  Syslog Destination: -
  Syslog Facility: -
  SNMP Trap Community: -
  Hide Parameter Values?: -
```

```
cluster1::> event destination modify -name support -mail
```
cluster1::> event destination show -name support

Name: support
Mail Destination: support.hq@company.com, support.remote@company.com
SNMP Destination: -
Syslog Destination: -
Syslog Facility: -
SNMP Trap Community: -
Hide Parameter Values?: -

event destination show

(DEPRECATED)-Display event destinations

Availability: This command is available to *cluster* administrators at the *admin* privilege level.

Description

*Note:* This command has been deprecated. It may be removed from a future release of Data ONTAP. Instead, use the "event notification destination" command set.

The *event destination show* command displays information about configured event destinations. An event destination is a list of addresses that receive event notifications. These addresses can be e-mail addresses, SNMP trap hosts, and syslog servers. Event destinations are used by event routes. Event routes describe which events generate notifications, and event destinations describe where to send those notifications.

Default destinations:

- **allevents** - A useful destination for all system events, though no events are routed to this destination by default.
- **asup** - Events routed to this destination trigger AutoSupport(tm). Only use this destination to send notifications to technical support. See *system node autosupport* for more information.
- **criticals** - A useful destination for critical events although no events are routed to this destination by default.
- **pager** - A useful destination for all events that are urgent enough to page a system administrator, though no events are routed to this destination by default.
- **traphost** - The default destination for all SNMP traps. You can also use the *system snmp traphost show* command to view SNMP recipients for the traphost default destination.

To add recipients to the default destination, use the *event destination modify* command.

*Note:* While you can use both host names and IP addresses with parameters, only IP addresses are stored. Unless all DNS and reverse-DNS operations complete successfully, IP addresses might appear in command output.

Parameters

{[-fields *fieldname*, ...]}

If you specify the -fields *fieldname*, ... parameter, the command output also includes the specified field or fields. You can use ‘-fields ?’ to display the fields to specify.

|[-facility]|

Displays only the syslog destinations and syslog facilities.
| [-instance ] |
| If you specify the `-instance` parameter, the command displays detailed information about all fields. |

| [-name <text>] - Name |
| Selects the destinations that match this parameter value. |

| [-name <mail address>,...] - Mail Destination |
| Selects the destinations that match this parameter value. |

| [-snmp <Remote IP>,...] - SNMP Destination |
| Selects the destinations that match this parameter value (SNMP trap hosts). |

| [-syslog <Remote IP>,...] - Syslog Destination |
| Selects the destinations that match this parameter value (syslog event notification daemons). |

| [-syslog-facility <Syslog Facility>] - Syslog Facility |
| Selects the destinations that match this parameter value. Valid values are: default, local0, local1, local2, local3, local4, local5, local6, and local7. |

| [-snmp-community <text>] - SNMP Trap Community |
| Selects the destinations that match this parameter value. |

| [-hide-parameters {true|false}] - Hide Parameter Values? |
| Selects the destinations that match this parameter value (true selects destinations that do not receive full event parameters, false selects destinations that receive full event parameters). Event parameters may be hidden to prevent sensitive information from being sent over non-secure channels. |

### Examples

The following example displays information about all event destinations:

```
cluster1::> event destination show

+----------+--------------------+--------------------+---------------------+-------+
| Name     | Mail Dest.          | SNMP Dest.         | Syslog Dest.        | Hide  |
|----------+--------------------+--------------------+---------------------+-------+
| allevents| -                  | -                  | logger.example.com  | -     |
| asup     | -                  | -                  | -                   | -     |
| criticals| oncall             | -                  | -                   | -     |
| pager    | pager@example.com  | -                  | -                   | -     |
| support.email | supportmgr | @example.com | techsupport | - |
|         | @example.com,      | -                  | -                   | -     |
|         | oncall             | @example.com      | -                   | -     |
| traphost | -                  | th0.example.com,   | -                   | -     |
|         |                    | th1.example.com    | -                   | -     |
+----------+--------------------+--------------------+---------------------+-------+
6 entries were displayed.
```

event log commands

Display the list of event occurrences

event log show

Display latest log events

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The event log show command displays the contents of the event log, which lists significant occurrences within the cluster. Use the event catalog show command to display information about events that can occur.

By default, the command displays EMERGENCY, ALERT and ERROR severity level events with the following information, with the most recent events listed first:

- The time at which the event occurred
- The node on which the event occurred
- The severity of the event
- The event's message

To display detailed information about events, use one or more of the optional parameters that affect how the command output is displayed and the amount of detail that is included. For example, to display all detailed event information, use the -detail parameter.

To display NOTICE, INFORMATIONAL or DEBUG severity level events, use the -severity parameter.

Parameters

[-fields <fieldname>, ...]
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

[[-detail]
Displays additional event information such as the sequence number of the event.

[[-detailltime]
Displays detailed event information in reverse chronological order.

[[-instance]]
If you specify the -instance parameter, the command displays detailed information about all fields.

[-node [<nodename> | local]] - Node
Displays a list of events for the node you specify. Use this parameter with the -seqnum parameter to display detailed information.

[-seqnum <Sequence Number>] - Sequence#
Selects the events that match this parameter value. Use with the -node parameter to display detailed information.

[-time <MM/DD/YYYY HH:MM:SS>] - Time
Selects the events that match this parameter value. Use the format: MM/DD/YYYY HH:MM:SS [-HH:MM]. You can specify a time range by using the ".." operator between two time statements.
show -time "08/13/2010 05:55:00".."08/13/2010 06:10:00"

Comparative time values are relative to "now". For example, to display only events that occurred within the last minute:

show -time >1m

[-severity (EMERGENCY|ALERT|ERROR|NOTICE|INFORMATIONAL|DEBUG)] - Severity

Selects the events that match this parameter value. Severity levels are as follows:

- EMERGENCY: Disruption.
- ALERT: Single point of failure.
- ERROR: Degradation.
- NOTICE: Information.
- INFORMATIONAL: Information.
- DEBUG: Debug information.

To display all events, including ones with severity levels of NOTICE, INFORMATIONAL and DEBUG, specify severity as follows:

show -severity <=DEBUG

[-ems-severity (NODE_FAULT|SVC_FAULT|NODE_ERROR|SVC_ERROR|WARNING|NOTICE|INFO|DEBUG|VAR)] - EMS Severity (privilege: advanced)

Selects the events that match this parameter value. Severity levels:

- NODE_FAULT: Data corruption has been detected or the node is unable to provide client service
- SVC_FAULT: A temporary loss of service, typically a transient software fault, has been detected
- NODE_ERROR: A hardware error that is not immediately fatal has been detected
- SVC_ERROR: A software error that is not immediately fatal has been detected
- WARNING: A high-priority message that does not indicate a fault
- NOTICE: A normal-priority message that does not indicate a fault
- INFO: A low-priority message that does not indicate a fault
- DEBUG: A debugging message
- VAR: A message with variable severity, selected at runtime.

[-source <text>] - Source

Selects the events that match this parameter value (typically a software module).

[-message-name <Message Name>] - Message Name

Selects the events that match this parameter value (string). Message names are descriptive, so filtering output by message name displays messages of a specific type.

[-event <text>] - Event

Selects the events that match this parameter value. The "event" field contains the full text of the event, including any parameters. For example, a wafl.vol.offline event will contain the name of the volume taken offline.
[-kernel-generation-num <integer>] - Kernel Generation Number (privilege: advanced)
Selects the events that match this parameter value. Only events that emanate from the kernel have kernel generation numbers.

[-kernel-sequence-num <integer>] - Kernel Sequence Number (privilege: advanced)
Selects the events that match this parameter value. Only events that emanate from the kernel have kernel sequence numbers.

[-action <text>] - Corrective Action
Selects the events that match this parameter value. The "action" field describes what steps, if any, you must take to remediate the situation.

[-description <text>] - Description
Selects the events that match this parameter value. The "description" field describes why the event was encountered and what it means.

[-filter-name <text>] - Filter Name
Selects the events that match this parameter value. Only events that were included by existing filters that match this value are displayed.

### Examples
Selects the events that match this parameter value. Use the format: MM/DD/YYYY HH:MM:SS [+- HH:MM]. You can specify a time range by using the ".." operator between two time statements.

```bash
show -time "08/13/2010 05:55:00".."08/13/2010 06:10:00"
```

Comparative time values are relative to "now". For example, to display only events that occurred within the last minute:

```bash
show -time >1m
```

Selects the events that match this parameter value. Severity levels are as follows:

- **EMERGENCY**: Disruption.
- **ALERT**: Single point of failure.
- **ERROR**: Degradation.
- **NOTICE**: Information.
- **INFORMATIONAL**: Information.
- **DEBUG**: Debug information.

To display all events, including ones with severity levels of NOTICE, INFORMATIONAL and DEBUG, specify severity as follows:

```bash
show -severity <=DEBUG
```

The following example displays the event log:

```
cluster1:/> event log show
            Time     Node        Severity      Event
            --------  -------------  ---------------
11/9/2015 13:54:19 node1 NOTICE        vifmgr.portup: A link up event was received on node node1, port e0a.
11/9/2015 13:54:19 node1 NOTICE        vifmgr.portup: A link up event was received on node node1, port e0d.
11/9/2015 13:54:19 node1 NOTICE        vifmgr.portup: A link up event was received on node node1, port e0a.
```

118 Commands: Manual Page Reference
This example demonstrates how to use a range with the `-time` parameter to display all events that occurred during an extended time period. It displays all events that occurred between 1:45pm and 1:50pm on November 9, 2010.

```
cluster1::> event log show -time "11/9/2015 13:45:00".."11/9/2015 13:50:00"
```

The `-time` parameter also accepts values that are relative to "now". The following example displays events that occurred more than one hour ago:

```
cluster1::event log> show -time <1h
```

Severity levels sort in the order opposite to what you might expect. The following example displays all events that have a severity level of ERROR or more severe:

```
cluster1::> event log show -severity <ERROR
```

### event mailhistory commands

(DEPRECATED)-Display the list of e-mailed events

### event mailhistory delete

(DEPRECATED)-Delete an e-mail history record

**Availability:** This command is available to cluster administrators at the `admin` privilege level.

**Description**

**Note:** This command has been deprecated. It may be removed from a future major release of Data ONTAP. Instead, use the "event notification history" command set.

The `event mailhistory delete` command deletes a record from the e-mail history.

To delete a record, you must know which node contains the record, and the record's sequence number. Use the `event mailhistory show` command to view this information.

**Parameters**

- `-node {<nodename> | local} - Node`
  
  Use this parameter to specify the name of the node that contains the e-mail history record to delete.

- `-seqnum <Sequence Number> - Sequence Number`
  
  Use this parameter to specify the sequence number of the e-mail history record to delete.
Examples

The following example deletes all mail-history records on node1:

```
cluster1::> event mailhistory delete -node node1 -seqnum *
```

`event mailhistory show` on page 120

### event mailhistory show

(DEPRECATED)-Display a list of e-mail history records

**Availability:** This command is available to cluster administrators at the `admin` privilege level.

**Description**

**Note:** This command has been deprecated. It may be removed from a future release of Data ONTAP. Instead, use the "event notification history" command set.

The `event mailhistory show` command displays a list of the event notifications that have been e-mailed. The command output depends on the parameters you specify with the command. By default, the command displays basic information about all notification e-mails that were sent.

To display detailed information about a specific mail-history record, run the command with the `-seqnum` parameter.

**Parameters**

```
[-fields <fieldname>, ...]
```

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

```
[-instance]
```

If you specify the `-instance` parameter, the command displays detailed information about all fields.

```
[-node <nodename> | local] - Node
```

Selects the mail-history records that match this parameter value.

```
[-seqnum <Sequence Number>] - Sequence Number
```

Selects the mail-history records that match this parameter value.

```
[-message-name <Message Name>] - Message Name
```

Selects the mail-history records that match this parameter value.

```
[-address <mail address>, ...] - Mail Address
```

Selects the mail-history records that match this parameter value.

```
[-time <MM/DD/YYYY HH:MM:SS>] - Transmission Time
```

Selects the mail-history records that match this parameter value.

```
[-message <text>] - Alert Message
```

Selects the mail-history records that match this parameter value (text pattern).

```
[-previous-time <MM/DD/YYYY HH:MM:SS>] - Previous Transmission Time
```

Selects the mail-history records that match this parameter value.

```
[-num-drops-since-previous <integer>] - Number of Drops Since Previous Transmission
```

Selects the mail-history records that match this parameter value (number of event drops since last transmission).
Examples
The following example displays detailed information about the mail-history record with the sequence number 20520:

```
cluster1::> event mailhistory show -seqnum 20520
Sequence Number: 20520
  Message Name:  wafl.vol.full
  Address: admin@example.com
  Time: 10/1/2008 14:06:24
  Node: node3
  Previous Time: 5/31/2007 00:33:22
  # Drops Since Prev: 0
  Mail Message:  wafl.vol.full: file system on volume vol0@vserver:28558fe3-2462-11da-85ab
               -000423bacd20 is full
```

event notification commands
Create, modify, delete and view event notifications.

event notification create
Create an event notification

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The event notification create command is used to create a new notification of a set of events defined by an event filter to one or more notification destinations.

Parameters
- filter-name <text> - Filter Name
  Use this mandatory parameter to specify the name of the event filter. Events that are included in the event filter are forwarded to the destinations specified in the destinations parameter.

  The filter name passed to this command must be an existing filter. For more information, see the event filter create command.

- destinations <text>, ... - List of Event Notification Destinations
  Use this mandatory parameter to specify the list of destinations to which the notification should be forwarded. Enter multiple destinations separated by a comma.

  The destination passed to this command must be an existing destination. For more information, see the event destination create command.

Examples
The following example creates an event notification for filter name "filter1" to destinations "email_dest, snmp-traphost and syslog_dest":

```
cluster1::> event notification destination show
Name            Type        Params   Destination
--------------  ----------  ------   ---------------------
email_dest      email       false    test@example.com
snmp-traphost   snmp        true     10.27.12.1 (from "system snmp traphost")
syslog_dest     syslog      false    10.23.12.1
3 entries were displayed.
cluster1::> event filter show -filter-name filter1
```

```
cluster1::> event notification destination show
Name            Type        Params   Destination
--------------  ----------  ------   ---------------------
email_dest      email       false    test@example.com
snmp-traphost   snmp        true     10.27.12.1 (from "system snmp traphost")
syslog_dest     syslog      false    10.23.12.1
3 entries were displayed.
cluster1::> event filter show -filter-name filter1
```

```
cluster1::> event notification destination show
Name            Type        Params   Destination
--------------  ----------  ------   ---------------------
email_dest      email       false    test@example.com
snmp-traphost   snmp        true     10.27.12.1 (from "system snmp traphost")
syslog_dest     syslog      false    10.23.12.1
3 entries were displayed.
cluster1::> event filter show -filter-name filter1
```
Filter Name | Rule | Message Name          | SNMP Trap Type | Severity |
------------|------|-----------------------|----------------|---------|
            |      |                       |                |         |
filter1     | 1    | exclude callhome.bad.ram | *              |         |
            | 2    | include callhome.*     | *              | ALERT, ERROR |
            | 3    | exclude *              | *              |         |

3 entries were displayed.

cluster1::> event notification create -filter-name filter1 -destinations email_dest, syslog_dest, snmp-traphost

cluster1::> event notification show

ID | Filter Name | Destinations
---|-------------|--------------
1  | filter1     | email_dest, syslog_dest, snmp-traphost

event notification delete

Delete event notifications

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The event notification delete command deletes an existing event notification.

Parameters

- \(-ID <integer>\) - Event Notification ID

  Use this parameter to specify the ID of the notification to be deleted.

Examples

The following example shows the deletion of event notification with ID 1:

cluster1::> event notification show

ID | Filter Name | Destinations
---|-------------|--------------
1  | filter1     | email_dest, syslog_dest, snmp-traphost

cluster1::> event notification delete -ID 1

cluster1::> event notification show

This table is currently empty.

event notification modify

Modify event notifications

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The event notification modify command is used to modify an existing notification.
Parameters

- **ID <integer>** - Event Notification ID
  
  Use this mandatory parameter to specify the ID of the notification to be modified.

- **[ -filter-name <text> ]** - Event Filter Name
  
  Use this parameter to specify the filter name to be modified.

- **[ -destinations <text>, ... ]** - List of Event Notification Destinations
  
  Use this parameter to specify the destinations to be modified. Enter multiple destinations separated by a comma.

  Provide the complete set of destinations to be modified. Individual destination cannot be added or removed.

Examples

The following example shows the modification of event notification with ID 1:

```
cluster1::> event notification show
ID     Filter Name       Destinations
-----  ----------------  -----------------
1      filter1           email_dest, syslog_dest, snmp-traphost
cluster1::> event notification modify -ID 1 -destinations email_dest, syslog_dest
cluster1::>  event notification show
ID     Filter Name       Destinations
-----  ----------------  -----------------
1      filter1           email_dest, syslog_dest
```

**event notification show**

Display event notifications

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**

The event notification show command is used to display the list of existing event notifications.

**Parameters**

```
{ [[ -fields <fieldname>, ... ]]
  If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

  [ [ -instance ]]
  If you specify the -instance parameter, the command displays detailed information about all fields.

  [-ID <integer>] - Event Notification ID
  Use this parameter to display the detailed information about the notification ID you specify.

  [-filter-name <text>] - Event Filter Name
  Use this parameter to display event notifications that use the filter-name you specify.

  [-destinations <text>, ...] - List of Event Notification Destinations
  Use this parameter to display event notifications that use the destinations you specify.
```

**Examples**

The following example displays the event notification:
event notification destination commands

Create, modify, delete and view event notification destinations.

event notification destination create

Create an event notification destination

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The event notification destination create command creates a new event notification destination of either email or syslog type.

The following system-defined notification destination is configured for your use:

• snmp-traphost - This destination reflects the configuration in "system snmp traphost".

Parameters

- **-name <text>** - Destination Name
  
  Use this mandatory parameter to specify the name of the notification destination that is to be created. An event notification destination name must be 2 to 64 characters long. Valid characters are the following ASCII characters: A-Z, a-z, 0-9, ",", and ".". The name must start and end with: A-Z, a-z, or 0-9.

- **-email <mail address>** - Email Destination
  
  Use this parameter to specify the email address to which event notifications will be sent. For events to properly generate email notifications, the event system must also be configured with an address and mail server from which the mail will be sent. See event config modify command for more information.

- **-syslog <text>** - Syslog Destination
  
  Use this parameter to specify syslog server host name or IP address to which syslog entries will be sent.

- **-rest-api-url <text>** - REST API Server URL
  
  Use this parameter to specify REST API server URL to which event notifications will be sent. Enter the full URL, which must start either with an http:// or https:// prefix. To specify a URL that contains a question mark, press ESC followed by the "?".
  
  If an https:// URL is specified, then Data ONTAP verifies the identity of the destination host by validating its certificate. If the Online Certificate Status Protocol (OCSP) is enabled for EMS, then Data ONTAP uses that protocol to determine the certificate's revocation status. Use the security config oscp show -application ems command to determine if the OCSP-based certificate revocation status check is enabled for EMS.

- **[-certificate-authority <text>]** - Client Certificate Issuing CA
  
  Use this parameter to specify the name of the certificate authority (CA) that signed the client certificate that will be sent in case mutual authentication with the REST API server is required. There can be multiple client certificates installed for the admin vserver in the cluster, and this parameter, along with the certificate-serial parameter, uniquely identifies which one.
  
  Use the security certificate show command to see the list of certificates installed in the cluster.
[-certificate-serial <text>] - Client Certificate Serial Number

Use this parameter to specify the serial number of the client certificate that will be sent in case mutual authentication with the REST API server is required.

Examples
The following example shows the creation of a new event notification destination of type email called "StorageAdminEmail":

```
cluster1::> event notification destination create -name StorageAdminEmail -email StorageAdmin@example.com
cluster1::> event notification destination show
```

```
Name            Type        Destination
--------------  ----------  ---------------------
StorageAdminEmail  email       StorageAdmin@example.com
snmp-traphost    snmp        10.30.40.10 (from "system snmp traphost")
```

2 entries were displayed.

The following example shows the creation of a new event notification destination of type rest-api called "RestApi":

```
cluster1::> event notification destination create -name RestApi -rest-api-url https://rest.example.com/rest
-cluster1-root-ca -certificate-serial 052213E60B7088

cluster1::> event notification destination show -name RestApi -instance
```

```
Destination Name: RestApi
Type of Destination: rest-api
Destination Values: https://rest.example.com/rest
Client Certificate Issuing CA: cluster1-root-ca
Client Certificate Serial Number: 052213E60B7088
```

**event notification destination delete**

Delete existing event destinations

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**
The event notification destination delete command deletes an event notification destination.

The following system-defined notification destination is configured for your use:

- snmp-traphost - This destination reflects the configuration in "system snmp traphost". To remove snmp-traphost addresses, use the system snmp traphost command.

**Parameters**
- **-name <text> - Destination Name**

  Use this mandatory parameter to specify the name of an event destination to be removed.

**Examples**
The following shows the examples of deleting event notification destinations:
cluster1::> event notification destination show

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Destination</th>
</tr>
</thead>
<tbody>
<tr>
<td>StorageAdminEmail</td>
<td>email</td>
<td><a href="mailto:StorageAdmin@example.com">StorageAdmin@example.com</a></td>
</tr>
<tr>
<td>StorageAdminSyslog</td>
<td>syslog</td>
<td>example.com</td>
</tr>
<tr>
<td>snmp-traphost</td>
<td>snmp</td>
<td>10.30.40.10 (from &quot;system snmp traphost&quot;)</td>
</tr>
</tbody>
</table>

3 entries were displayed.

ccluster1::> event notification destination delete -name StorageAdminEmail

ccluster1::> event notification destination show

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Destination</th>
</tr>
</thead>
<tbody>
<tr>
<td>StorageAdminSyslog</td>
<td>syslog</td>
<td>example.com</td>
</tr>
<tr>
<td>snmp-traphost</td>
<td>snmp</td>
<td>10.30.40.10 (from &quot;system snmp traphost&quot;)</td>
</tr>
</tbody>
</table>

2 entries were displayed.

ccluster1::> event notification destination delete -name Storage*

ccluster1::> event notification destination show

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Destination</th>
</tr>
</thead>
<tbody>
<tr>
<td>snmp-traphost</td>
<td>snmp</td>
<td>10.30.40.10 (from &quot;system snmp traphost&quot;)</td>
</tr>
</tbody>
</table>

1 entries were displayed.

*system snmp traphost* on page 1436

event notification destination modify

Modify an event notification destination

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**
The *event notification destination modify* command modifies event notification destination.

The following system-defined notification destination is configured for your use:

- snmp-traphost - This destination reflects the configuration in "system snmp traphost". To modify traphost addresses, use the *system snmp traphost* command.

**Parameters**

- **-name <text> - Destination Name**
  
  Use this mandatory parameter to specify the name of an event notification destination to be modified. The name of the destination must already exist.

- **[-email <mail address>] - Email Destination**
  
  Use this parameter to specify a new value of email address to replace the current address in the event notification destination. The parameter is specified only when the event notification destination type is already "email". It is not allowed to specify the parameter for a destination that already has another type of destination address.

- **[-syslog <text>] - Syslog Destination**
  
  Use this parameter to specify a new syslog server host name or IP address to replace the current address of the event notification destination. The parameter is specified only when the event notification destination type is
already "syslog". It is not allowed to specify the parameter for a destination that already has another type of destination address.

```
[-rest-api-url <text>] - REST API Server URL
```

Use this parameter to specify a new REST API server URL to replace the current address of the event notification destination. Enter the full URL, which must start either with an http:// or https:// prefix. To specify a URL that contains a question mark, press ESC followed by the "?". If an https:// URL is specified, then Data ONTAP verifies the identity of the destination host by validating its certificate. If the Online Certificate Status Protocol (OCSP) is enabled for EMS, then Data ONTAP uses that protocol to determine the certificate's revocation status. Use the `security config oscp show -application ems` command to determine if the OCSP-based certificate revocation status check is enabled for EMS. The parameter is specified only when the event notification destination type is already "rest-api". It is not allowed to specify the parameter for a destination that already has another type of destination address.

```
[-certificate-authority <text>] - Client Certificate Issuing CA
```

Use this parameter to specify a new value of the certificate authority (CA) to replace the current value in the event notification destination. There can be multiple client certificates installed for the admin vserver in the cluster, and this parameter, along with the `certificate-serial` parameter, uniquely identifies which one. Use the `security certificate show` command to see the list of certificates installed in the cluster.

```
[-certificate-serial <text>] - Client Certificate Serial Number
```

Use this parameter to specify a new serial number of the client certificate to replace the current value in the event notification destination.

### Examples

The following example shows the modification of event notification destinations:

```
cluster1::> event notification destination show
Name            Type        Destination
--------------  ----------  ---------------------
StorageAdminEmail email  Storage@example.com
StorageAdminSyslog syslog  example.com
snmp-traphost snmp  10.30.40.10 (from "system snmp traphost")
3 entries were displayed.

cluster1::> event notification destination modify -name StorageAdminEmail -email StorageAdmin@example.com

cluster1::> event notification destination show
Name            Type        Destination
--------------  ----------  ---------------------
StorageAdminEmail email  StorageAdmin@example.com
StorageAdminSyslog syslog  example.com
snmp-traphost snmp  10.30.40.10 (from "system snmp traphost")
3 entries were displayed.
```

The following example shows how to clear the client certificate configuration when mutual authentication with the REST API server is no longer required:

```
cluster1::> event notification destination show -name RestApi -instance Destination Name: RestApi
Type of Destination: rest-api
Destination Values: https://rest.example.com/rest
Client Certificate Issuing CA: cluster1-root-ca
Client Certificate Serial Number: 052213E60B7088

cluster-1::> event notification destination modify -name RestApi -certificate-authority - -certificate-serial -
```

event notification destination show

Display event notification destinations

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The event notification destination show command displays event notification destinations. Note: In the case of a rest-api destination type, OCSP information is not included. It's available in security config ocsp show -app ems command.

Parameters

\{-fields <fieldname>, ...\}
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use `-fields ?' to display the fields to specify.

\{-instance\}
If you specify the -instance parameter, the command displays detailed information about all fields.

\{-name <text>\} - Destination Name
Use this optional parameter to display information of an event notification destination that has the specified name.

\{-type snmp|email|syslog|rest-api\} - Type of Destination
Use this optional parameter to display information of event notification destinations that have the specified destination type.

\{-destination <text>, ...\} - Destination
Use this optional parameter to display information of event notification destinations that have the specified destination address. Enter multiple addresses separated by a comma.

\{-server-ca-present true|false\} - Server CA Certificates Present?
Use this optional parameter to display information of event notification destinations that have the specified server-ca-present value. This field indicates whether there are certificates of the server-ca type exist in the system. If not, event messages will not be sent to a rest-api type destination having an HTTPS URL.

\{-certificate-authority <text>\} - Client Certificate Issuing CA
Use this optional parameter to display information of event notification destinations that have the specified certificate authority name.

\{-certificate-serial <text>\} - Client Certificate Serial Number
Use this optional parameter to display information of event notification destinations that have the specified certificate serial number.
[-certificate-valid {true|false}] - Client Certificate Valid?

Use this optional parameter to display information of event notification destinations that have the specified certificate-valid value. This field indicates whether the client certificate specified by the certificate-authority and certificate-serial fields is valid. If not, and if the REST API server requires client authentication, event messages will not be sent to the server.

Examples

The following shows examples of "event notification destination show":

```
cluster1::> event notification destination show
Name            Type        Destination
--------------  ----------  ---------------------
StorageAdminEmail  email       StorageAdmin@example.com
StorageAdminSyslog  syslog      example.com
snmp-traphost       snmp        10.30.40.10 (from "system snmp traphost")
RestApi             rest-api    https://rest.example.com/rest
4 entries were displayed.
```

```
cluster1::> event notification destination show -type snmp -instance
  Destination Name: snmp-traphost
  Type of Destination: snmp
  Destination values: 10.30.40.10 (from "system snmp traphost")
```

event notification history commands

The history directory

event notification history show

Display latest events sent to destination

**Availability**: This command is available to *cluster* administrators at the *admin* privilege level.

**Description**

The *event notification history show* command displays a list of event messages that have been sent to a notification destination. Information displayed by the command for each event is identical to that of the *event log show* command. This command displays events sent to a notification destination while the *event log show* command displays all events that have been logged.

**Parameters**

```
[-fields <fieldname>,...]
```

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

```
[-instance ]
```

If you specify the `-instance` parameter, the command displays detailed information about all fields.

**-destination <text>** - Destination

Specifies the destination to which event messages have been sent to be displayed.

**-node {<nodename>|local}}** - Node

 Displays a list of events for the node you specify. Use this parameter with the `-seqnum` parameter to display detailed information.
-[segnum <Sequence Number>] - Sequence#
Selects the events that match this parameter value. Use with the -node parameter to display detailed information.

-[time <MM/DD/YYYY HH:MM:SS>] - Time
Selects the events that match this parameter value. Use the format: MM/DD/YYYY HH:MM:SS [+- HH:MM]. You can specify a time range by using the ".." operator between two time statements.

-[severity (EMERGENCY|ALERT|ERROR|NOTICE|INFORMATIONAL|DEBUG)] - Severity
Selects the events that match this parameter value. Severity levels are as follows:
- EMERGENCY - Disruption.
- ALERT - Single point of failure.
- ERROR - Degradation.
- NOTICE - Information.
- INFORMATIONAL - Information.
- DEBUG - Debug information.

-[message-name <Message Name>] - Message Name
Selects the events that match this parameter value (string). Message names are descriptive, so filtering output by message name displays messages of a specific type.

-[event <text>] - Event
Selects the events that match this parameter value. This parameter is useful when entered with wildcards. The "event" field contains the full text of the event, including any parameters. For example, the wafl.vol.offline event displays the name of the volume that is taken offline.

**Examples**

The following example displays all the events which match "important-events" filter and forwarded to the "snmp-traphost" destination:

```
cluster1::> event filter show
Filter Name Rule Position Type Message Name SNMP Trap Type Severity
---------- -------- --------- ---------------------- --------------- ------
default-trap-events
1 include *      * EMERGENCY, ALERT
2 include *      Standard, Built-in
3 exclude *      *
important-events
1 include *      * EMERGENCY, ALERT
2 include callhome.*   * ERROR
3 exclude *      *
no-info-debug-events
1 include *      * EMERGENCY, ALERT, ERROR
NOTICE
2 exclude *      *
8 entries were displayed.

cluster1::> event notification destination show
Name Type Destination
---------- ---------- ------------
snmp-traphost snmp 192.168.10.40 (from "system snmp traphost")

cluster1::> event notification show
ID Filter Name Destinations
------ ----------------- -----------------
1 important-events snmp-traphost

cluster1::>event notification history show -destination snmp-traphost
```

130 Commands: Manual Page Reference
Time                Node             Severity      Event
------------------- ---------------- ------------- -----------------------------

2 entries were displayed.

**event route commands**

(DEPRECATED)–Manage the mapping between events and destinations

**event route add-destinations**

(DEPRECATED)-Add destination(s) to an event definition

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**

**Note:** This command has been deprecated. It may be removed from a future release of Data ONTAP. Instead, use the "event notification" command set.

The event route add-destinations command adds destinations to an event route. Any existing destinations assigned to the route are not removed.

The destinations you add must already exist. See the documentation for the event destination create command for information about creating destinations. To show all existing destinations and their attributes, use the event destination show command. To remove destinations from an event route, use the event route remove-destinations command.

You can use extended queries with such parameters as -severity and -snmp-support to specify multiple events that meet certain criteria. See examples below that show how to use extended queries.

**Parameters**

- `-message-name <Message Name>` - Message Name
  Specify the message name of the event you are modifying. You can use wildcards to specify a family of events or type of event.

- `[ -severity {EMERGENCY|ALERT|ERROR|NOTICE|INFORMATIONAL|DEBUG} ]` - Severity
  Use this optional parameter to specify a set of events that match this parameter value. You must use the -message-name parameter with wildcards to specify the family of events or type of events.

- `-destinations <Event Destination>, ...` - Destinations
  Specify a comma-separated list of destinations to which notifications for the named event are sent. These destinations will be added to any existing destinations assigned to this event route.

**Examples**

The following example specifies that all RAID events go to the destinations named support.email, mgr.email, and sreng.pager:

```
cluster1:/> event route add-destinations -message-name raid* -destinations support.email,mgr.email,sreng.pager
```

The following example specifies that all alert, and emergency events go to the destination named test_dest:
The following example specifies that all alert events that support a SNMP trap go to the destination named traphost. In this example, because the -snmp-support parameter is specified as part of extended queries, the -severity parameter must also be specified in the extended queries:

```
cluster1::> event route add-destinations {-snmp-support true -severity ALERT} -destinations traphost
```

- event route remove-destinations on page 133

### event route modify

(DEPRECATED)-Modify an event's destination, reporting threshold, or both

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**

**Note:** This command has been deprecated. It may be removed from a future release of Data ONTAP. Instead, use the "event notification" command set.

Use the event route modify command to modify an event's destination, frequency threshold, and time threshold. The event's destination must already exist; see the documentation for the event destination create command for information about creating destinations. The frequency threshold and time threshold prevent multiple event notifications in a brief period of time.

You can use extended queries with such parameters as -severity and -snmp-support to specify multiple events that meet certain criteria. See examples provided in the event route add-destinations command manpage that show how to use extended queries.

The frequency threshold specifies the number of times an event occurs before a repeat notification of the event is sent; for instance, a frequency threshold of 5 indicates that a notification is sent every fifth time an event occurs. The time threshold specifies the number of seconds between notifications for an event; for instance, a time threshold of 120 indicates that a notification is sent only if it has been two minutes or more since the last notification for that event was sent.

If both the frequency threshold and time threshold are set, a notification is sent if either threshold is met. For instance, if the frequency threshold is set to 5 and the time threshold is set to 120, and the event occurs more than five times within two minutes, a notification is sent. If both thresholds are set to 0 (zero) or empty ("-" or "'"), there is no suppression of multiple event notifications.

**Parameters**

- **-message-name <Message Name> - Message Name**
  Specify the message name of the event you are modifying. You can use wildcards to specify a family of events or type of event.

- **[-severity {EMERGENCY|ALERT|ERROR|NOTICE|INFORMATIONAL|DEBUG}] - Severity**
  Use this optional parameter to specify a set of events that match this parameter value. You must use the -message name parameter with wildcards to specify the family of events or type of events.

- **[-destinations <Event Destination>, ...] - Destinations**
  Use this optional parameter to specify a comma-separated list of destinations to which notifications for the named event are sent. Using this parameter replaces the current list of destinations with the list of destinations
you specify. To add or remove individual destinations from the current list, use `event route add-destinations` or `event route remove-destinations`.

`[-frequencythreshold <integer>]` - Number of Drops Between Transmissions

Specifies the number of event notifications that must occur within the `timethreshold` period before a repeat notification is sent.

`[-timethreshold <integer>]` - Dropping Interval (Seconds) Between Transmissions

If multiple notifications of an event occur within this many seconds, only the first notification is sent. Multiple notifications will be sent during this time period only if the `frequencythreshold` quantity is exceeded.

---

**Examples**

The following example modifies all RAID events to send messages to a destination named "support.email", and specify that multiple messages should only be sent if and event occurs more than five times within 60 seconds.

```bash
cluster1::> event route modify -messagename raid* -destinations support.email -frequencythreshold 5 -timethreshold 60
```

---

**event route remove-destinations**

(DEPRECATED)-Remove destination(s) from an event definition

**Availability:** This command is available to cluster administrators at the `admin` privilege level.

**Description**

**Note:** This command has been deprecated. It may be removed from a future release of Data ONTAP. Instead, use the "event notification" command set.

The `event route remove-destinations` command can be used to remove existing destinations from an event route. This command removes only the specified destinations from the route, leaving any other destinations assigned to that route.

The named destinations are not deleted, just removed from the specified event route. To delete a destination entirely, use the `event destination delete` command. To show all existing destinations and their attributes, use the `event destination show` command.

You can use extended queries with such parameters as `-severity` and `-snmp-support` to specify multiple events that meet certain criteria. See examples provided in the `event route add-destinations` command manpage that show how to use extended queries.

**Parameters**

- `-message-name <Message Name>` - Message Name
  
  Specify the message name of the event you are modifying. You can use wildcards to specify a family of events or type of event.

- `[-severity {EMERGENCY|ALERT|ERROR|NOTICE|INFORMATIONAL|DEBUG}]` - Severity
  
  Use this optional parameter to specify a set of events that match this parameter value. You must use the `-message-name` parameter with wildcards to specify the family of events or type of events.

- `-destinations <Event Destination>, ...` - Destinations
  
  Specify a comma-separated list of destinations to remove from the event's list of destinations.
Examples

The following example specifies that the destination named "mgr.email" should no longer receive notifications of RAID events.

```
cluster1::> event route remove-destinations -message-name raid* -destinations mgr.email
```

Related references

- `event destination delete` on page 111
- `event destination show` on page 114
- `event route add-destinations` on page 131

---

**event route show**

(DEPRECATED)-Display event routes

**Availability:** This command is available to `cluster` administrators at the `admin` privilege level.

**Description**

**Note:** This command has been deprecated. It may be removed from a future release of Data ONTAP. Instead, use the "event catalog" command set.

This command displays information about event routes. Event routes describe which events generate notifications. A route specifies what to watch for, whom to notify, and what to do should a particular event occur. By default, the command displays the following information:

- Message name of the event
- Severity of the event
- Destinations for event notifications
- Frequency threshold for event notifications
- Time threshold for event notifications

To display detailed information about a specific event route, run the command with the `-message-name` parameter, and specify the name of the message. The detailed view adds the following information:

- Full description of the event
- Action to be taken to address the event

You can specify additional parameters to limit output to the information that matches those parameters. For example, to display information only about events with a message name that begins with "raid", run the command with the `-message-name raid*` parameter. You can enter either a specific text string or a wildcard pattern.

**Parameters**

```
[-fields <fieldname>, ...]
```

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

```
[-instance]
```

If you specify the `-instance` parameter, the command displays detailed information about all fields.

```
[-message-name <Message Name>] - Message Name
```

Selects the event routes that match this parameter value.
[-severity {EMERGENCY|ALERT|ERROR|NOTICE|INFORMATIONAL|DEBUG}] - Severity

Selects the event routes that match this parameter value. Valid values:

- EMERGENCY - Disruption
- ALERT - Single point of failure
- ERROR - Degradation
- NOTICE - Information
- INFORMATIONAL - Information
- DEBUG - Debug information

[-action <text>] - Corrective Action

Selects the events that match this parameter value. This parameter is most useful when entered with wildcards. The "action" field describes what steps, if any, you must take to remedy the situation.

[-description <text>] - Description

Selects the events that match this parameter value. This parameter is most useful when entered with wildcards. The "description" field describes why the event was encountered and what it means.

[-snmp-support {true|false}] - Supports SNMP trap

Selects the event routes that match this parameter value.

[-destinations <Event Destination>,...] - Destinations

Selects the event routes that match this parameter value. A destination is a list of email addresses, SNMP clients, and sylogs.

[-frequencythreshold <integer>] - Number of Drops Between Transmissions

Selects the event routes that match this parameter value (number of events since previous notification).

[-timethreshold <integer>] - Dropping Interval (Seconds) Between Transmissions

Selects the event routes that match this parameter value.

Examples

The following example displays information about all event routes:

<table>
<thead>
<tr>
<th>Message</th>
<th>Severity</th>
<th>Destinations</th>
<th>Freq</th>
<th>Time</th>
</tr>
</thead>

</tbody>
</table>

...
event snmphistory commands

(DEPRECATED)-Display the list of SNMP-trap events

event snmphistory delete

(DEPRECATED)-Delete an SNMP trap history record

Availability: This command is available to cluster administrators at the admin privilege level.

Description

Note: This command has been deprecated. It may be removed from a future release of Data ONTAP. Instead, use the "event notification history" command set.

The event snmphistory delete command deletes an SNMP trap-history record. To delete a record, you will need to know which node generated the event, and you will need to know the sequence number of that event in the trap-history.

Use the event snmphistory show command to display a list of trap-history records and their sequence numbers.

Parameters

-node {<nodename>|local} - Node

Use this parameter to specify the name of the node that contains the snmp history record to delete.

-seqnum <Sequence Number> - Sequence Number

Use this parameter to specify the sequence number of the SNMP trap-history record to delete.

Examples

The following example deletes all SNMP trap-history records on node1:

```
cluster1::> event snmphistory delete -node node1 -seqnum *
```

Related references

event snmphistory show on page 136

event snmphistory show

(DEPRECATED)-Display a list of SNMP trap history records

Availability: This command is available to cluster administrators at the admin privilege level.

Description

Note: This command has been deprecated. It may be removed from a future release of Data ONTAP. Instead, use the "event notification history" command set.

The event snmphistory show command displays a list of event notifications that have been sent to SNMP traps. The command output depends on the parameters specified with the command. By default, the command displays general information about all trap-history records.

To display detailed information about a specific trap-history record, run the command with the -seqnum parameter.
Parameters

`[-fields <fieldname>, ...]`

If you specify the `[-fields <fieldname>, ...]` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

`[-instance]`

If you specify the `[-instance]` parameter, the command displays detailed information about all fields.

`[-node (<nodename>|local)] - Node`

Selects the trap-history records that match this parameter value (text pattern).

`[-seqnum <Sequence Number>] - Sequence Number`

Selects the trap-history records that match this parameter value (sequence number).

`[-message-name <Message Name>] - Message Name`

Selects the trap-history records that match this parameter value.

`[-address <text>, ...] - SNMP Client Address`

Selects the trap-history records that match this parameter value (IP address).

`[-time <MM/DD/YYYY HH:MM:SS>] - Transmission Time`

Selects the trap-history records that match this parameter value.

`[-message <text>] - Alert Message`

Selects the trap-history records that match this parameter value (text pattern).

`[-previous-time <MM/DD/YYYY HH:MM:SS>] - Previous Transmission Time`

Selects the trap-history records that match this parameter value.

`[-num-drops-since-previous <integer>] - Number of Drops Since Previous Transmission`

Selects the trap-history records that match this parameter value (number of event drops since last transmission).

Examples

The following example displays information about all SNMP trap-history records:

```
cluster1::> event snmphistory show
Seq # Message Name          Address   Node  Time
----- --------------------- --------- ----- ------------------
12481 raid.mirror.restrict  10.0.2.20 node0 4/14/2008 15:11:04
12482 aggrcopy.dst.noMemory 10.0.2.20 node0 4/14/2008 14:52:54
12483 raid.mirror.restrict  10.0.2.21 node1 4/14/2008 14:41:04
```

**event status commands**

Display the status of events, including occurrences and drops

**event status show**

Display event status

**Availability:** This command is available to cluster administrators at the `admin` privilege level.

**Description**

The `event status show` command summarizes information about occurrences of events. For detailed information about specific occurrences of events, use the `event log show` command.
Parameters
{[-fields <fieldname>, ...]

If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use -fields ? to display the fields to specify.

[-instance ]

If you specify the -instance parameter, the command displays detailed information about all fields.

[-node {<nodename> | local}] - Node

Selects the event records that match this parameter value. Events are tracked on a node-by-node basis, rather than being rolled up cluster-wide.

[-message-name <Message Name>] - Message Name

Selects the event records that match this parameter value. The message name is a short descriptive string. Filtering output by message name displays messages of a specific type.

[-indications <integer>] - Number of Indications

Selects the event records that match this parameter value. This parameter is most useful when used with a range, such as using the range ">20" to display only events that have been posted more than 20 times.

[-drops <integer>] - Number of Drops

Selects the event records that match this parameter value.

[-last-time-occurred <MM/DD/YYYY HH:MM:SS>] - Last Indication Time

Selects the event records that match this parameter value.

[-last-time-dropped <MM/DD/YYYY HH:MM:SS>] - Last Suppressed Indication Time

Selects the event records that match this parameter value.

[-last-time-processed <MM/DD/YYYY HH:MM:SS>] - Last Processed Indication Time

Selects the event records that match this parameter value.

Selects the event records that match this parameter value.

[-last-hour-histogram <integer>, ...] - 60-minute Histogram (privilege: advanced)

Use this parameter with the -fields parameter to display the "last hour" histogram for each event type. The last hour histogram records the number of times each event occurred in the last hour. The histogram is divided into sixty buckets, and each bucket collects one minute's events. The buckets display with the most recent event first.

[-last-day-histogram <integer>, ...] - 24-hour Histogram (privilege: advanced)

Use this parameter with the -fields parameter to display the "last day" histogram for each event type. The last day histogram records the number of times each event occurred in the last day. The histogram is divided into 24 buckets, and each bucket collects one hour's events. The buckets display with the most recent event first.

[-last-week-histogram <integer>, ...] - 7-day Histogram (privilege: advanced)

Use this parameter with the -fields parameter to display the "last week" histogram for each event type. The last week histogram records the number of times each event occurred in the last week. The histogram is divided into 7 buckets, and each bucket collects one day's events. The buckets display with the most recent event first.

[-severity {NODE_FAULT|SVC_FAULT|NODE_ERROR|SVC_ERROR|WARNING|NOTICE|INFO|DEBUG|VAR}] - Severity

Selects events that have the event severity you specify. Severity levels sort with the most severe levels first. Severity levels:

• NODE_FAULT - The node has detected data corruption, or is unable to provide client service.
- **SVC_FAULT** - The node has detected a temporary loss of service. Typically, this is caused by a transient software fault.
- **NODE_ERROR** - The node has detected a hardware error that is not immediately fatal.
- **SVC_ERROR** - The node has detected a software error that is not immediately fatal.
- **WARNING** - A high-priority message that does not indicate a fault.
- **NOTICE** - A normal-priority message that does not indicate a fault.
- **INFO** - A low-priority message that does not indicate a fault.
- **DEBUG** - A debugging message. These messages are typically suppressed.
- **VAR** - These messages have variable severity. Severity level for these messages is selected at runtime.

The examples below illustrate how to query on severity.

### Examples

The following example displays recent event-occurrence status for node1:

```
cluster1::> event status show -node node1
Node Message                      Occurs Drops Last Time
----------------- ---------------------------- ------ ----- -------------------
node1 raid.spares.media_scrub.start 6      0     3/11/2010 15:59:00
node1 raid.uninitialized.parity.vol 3      0     3/11/2010 15:58:28
node1 raid.vol.state.online         3      0     3/11/2010 15:58:29
node1 reg.defaultCommit.set.timeTaken 1      0     3/11/2010 15:58:28
node1 sscsitgt.ha.state.changed     2      0     3/11/2010 15:58:28
node1 ses.multipath.notSupported    2      0     3/11/2010 15:58:43
node1 sk.hog.runtime                1      0     3/11/2010 15:58:28
node1 snmp.agent.msg.access.denied  1      0     3/11/2010 15:58:28
node1 snmp.link.up                  6      0     3/11/2010 15:58:28
node1 tar.csum.mismatch             2      0     3/11/2010 15:58:28
node1 tar.extract.success           2      0     3/11/2010 15:58:28
node1 vifmgr.lifsuccessfullymoved   3      0     3/11/2010 15:58:46
node1 vifmgr.portdown               1      0     3/11/2010 15:58:48
node1 vifmgr.portup                 5      0     3/11/2010 15:58:48
node1 vifmgr.startedsuccessfully    1      0     3/11/2010 15:58:43
```

The following example displays a summary of events which are warnings or more severe:

```
cluster1::> event status show -node node1 -severity <=warning -fields indications,drops,severity
node message-name indications drops severity
------- ------------------------ ----------- ----- --------
node1 api.output.invalidSchema      5463        840   WARNING
node1 callhome.dsk.config          1           0     WARNING
node1 callhome.sys.config          1           0     WARNING
node1 callhome.sys.config          1           0     SVC_ERROR
node1 cecce_log.dropped            145         0     WARNING
node1 cecce_log.entry              5           0     WARNING
node1 cecce_log.entry_no_syslog    4540        218   WARNING
node1 cecce_log.summary            5           0     WARNING
node1 cf.fm.noPartnerVariable      5469        839   WARNING
node1 cf.fm.notkoveBadMbox          1           0     WARNING
node1 cf.fm.notkoveClusterDisable  1           0     WARNING
node1 cf.fm.backupsMessboxError     1           0     WARNING
node1 cf.takeover.disabled          23          0     WARNING
node1 cmsds.sysconf.logErr            1          0     NODE_ERROR
node1 config.noPartnerDisks         1           0     NODE_ERROR
node1 fc1.initiation.failed         2           0     NODE_ERROR
node1 fcp.service.adapter            1          0     WARNING
node1 ffmpeg.BlobNotFound            1          0     WARNING
node1 ha.takeoverImpNotDef           1          0     WARNING
node1 httpd.config.mime.missing     2           0     WARNING
node1 mgr.opsmgr.autoreg.norec      1           0     WARNING
node1 monitor.globalStatus.critical 1           0     NODE_ERROR
```

---

**event status commands**
The example below demonstrates using the `probability` parameter and `fields` parameter together to display a list of events that might be suppressed.

```
cluster1::event*> status show -node node1 -probability > 9 -fields probability

node        message-name probability ------------- ----------
node1       app.log.crit 11%
node1       kern.syslog.msg 99%
node1       raid.spares.media_scrub.start 84%
node1       raid.spares.media_scrub.suspend 86%
```

4 entries were displayed.

**Job Commands**

Manage jobs and job schedules

The job commands enable you to manage jobs and schedules. A job is defined as any asynchronous operation.

**job delete**

Delete a job

**Availability:** This command is available to cluster and Vserver administrators at the admin privilege level.

**Description**

The job delete command deletes a job. Use the `job show` command to view a list of running jobs that can be deleted.

**Parameters**

- `-id <integer>` - Job ID
  
  The numeric ID of the job you want to delete. A job ID is a positive integer.

- `[-vserver <vserver name>]` - Owning Vserver
  
  Use this parameter to specify the name of the Vserver that owns the job.

**Examples**

The following example deletes the job that has ID 99:

```
cluster1::> job delete -id 99
```

job show on page 142

job pause

Pause a job

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description

The job pause command pauses a job. Use the job resume command to resume a paused job. Use the job show command to view a list of running jobs that can be paused.

Parameters

- id <integer> - Job ID
  
The numeric ID of the job you want to pause. A job ID is a positive integer.

[-vserver <vserver name>] - Owning Vserver

Use this parameter to specify the name of the Vserver that owns the job.

Examples

The following example pauses the job that has ID 183:

cluster1::> job pause -id 183

Related references

job resume on page 141

job show on page 142

job resume

Resume a job

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description

The job resume command resumes a job that was previously paused by using the job pause command. Use the job show command to view a list of paused jobs that can be resumed.

Parameters

- id <integer> - Job ID
  
The numeric ID of the paused job to be resumed. A job ID is a positive integer.

[-vserver <vserver name>] - Owning Vserver

Use this parameter to specify the name of the Vserver that owns the job.

Examples

The following example resumes the paused job that has ID 183:
job show

Display a list of jobs

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The job show command displays information about jobs. By default, the command displays information about all current jobs.

To display detailed information about a specific job, run the command with the -id parameter.

You can specify additional parameters to select information that matches the values you specify for those parameters. For example, to display information only about jobs running on a specific node, run the command with the -node parameter.

Parameters
[-fields <fieldname>, ...]
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

| [-inprogress ]
Display the job ID, the job name, the owning Vserver, and the progress of the job.

| [-jobstate ]
Displays information about each job's state, including the queue state, whether the job was restarted, and when the job has completely timed out.

| [-sched ]
Displays the job ID, the job name, the owning Vserver, and the schedule on which the job runs.

| [-times ]
Displays the job ID, the job name, the owning Vserver, the time when the job was last queued, the time when the job was last started, and the time when the job most recently ended.

| [-type ]
Displays the job ID, the job name, the job type, and the job category.

| [-jobuuid ] (privilege: advanced)
Displays the job ID, the job name, the owning Vserver, and the job UUID.

| [-instance ]
If you specify the -instance parameter, the command displays detailed information about all fields.

[-id <integer>] - Job ID
Selects the jobs that match the ID or range of IDs that you specify.

[-vserver <vserver name>] - Owning Vserver
Selects jobs that are owned by the specified Vserver.
[-name <text>] - Name
Selects the jobs that match this parameter value.

[-description <text>] - Description
Selects the jobs that match this parameter value.

[-priority {Low|Medium|High|Exclusive}] - Priority
Selects the jobs that match this parameter value.

[-node <nodename>] - Node
Selects the jobs that match this parameter value.

[-affinity {Cluster|Node}] - Affinity
Selects the jobs that match this parameter value.

[-schedule <job_schedule>] - Schedule
Selects the jobs that match this parameter value.

[-queuetime <MM/DD HH:MM:SS>] - Queue Time
Selects the jobs that match this parameter value.

[-starttime <MM/DD HH:MM:SS>] - Start Time
Selects the jobs that match this parameter value.

[-endtime <MM/DD HH:MM:SS>] - End Time
Selects the jobs that match this parameter value.

[-dropdeadtime <MM/DD HH:MM:SS>] - Drop-dead Time
Selects the jobs that match this parameter value.

[-restarted {true|false}] - Restarted?
Selects the jobs that match this parameter value.

[-state {Initial|Queued|Running|Waiting|Pausing|Paused|Quitting|Success|Failure|Reschedule|Error|Quit|Dead|Unknown|Restart|Dormant}] - State
Selects the jobs that match this parameter value.

[-code <integer>] - Status Code
Selects the jobs that match this parameter value.

[-completion <text>] - Completion String
Selects the jobs that match this parameter value.

[-jobtype <text>] - Job Type
Selects the jobs that match this parameter value.

[-category <text>] - Job Category
Selects the jobs that match this parameter value.

[-uuid <UUID>] - UUID (privilege: advanced)
Selects the jobs that match this parameter value.

[-progress <text>] - Execution Progress
Selects the jobs that match this parameter value.

[-username <text>] - User Name
Selects the jobs that match this parameter value.

[-restart-is-delayed-by-module <text>] - Restart Is Delayed by Module
Selects jobs which are or were delayed by the specified module during the restart. For example:
MCC_SWITCHBACK
The following example displays information about all jobs on the node named node1:

```
cluster1::> job show -node node1

Owning Job ID Name             Vserver   Node         State
------ ---------------- --------- ------------ ----------
308114 mirror-daily-3587206 node-vserver node1        Running
            Descr:Auto-replicate to 1 mirror(s)
308115 mirror-daily-3618985 node-vserver node1        Running
            Descr:Auto-replicate to 1 mirror(s)
308116 mirror-daily-3619010 node-vserver node1        Queued
            Descr:Auto-replicate to 1 mirror(s)
308117 mirror-daily-3749547 node-vserver node1        Queued
            Descr:Auto-replicate to 1 mirror(s)
4 entries were displayed.
```

---

**job show-bynode**

Display a list of jobs by node

**Availability:** This command is available to cluster and Vserver administrators at the `admin` privilege level.

**Description**

The `job show-bynode` command displays information about jobs on a per-node basis. The command output depends on the parameters specified with the command. If no parameters are specified, the command displays information about all jobs in the cluster that are currently owned by a node.

To display detailed information about a specific job, run the command with the `-id` parameter. The detailed view includes all of the default information plus additional items.

You can specify additional parameters to display only information that matches the values you specify for those parameters. For example, to display information only about jobs running on a specific node, run the command with the `-node` parameter.

**Parameters**

```
[-fields <fieldname>, ...]
```

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use ‘-fields ?’ to display the fields to specify.

```
[-instance ]
```

If you specify the `-instance` parameter, the command displays detailed information about all fields.

```
[-node <nodename> | local] - Node
```

Use this parameter to display information only about the jobs that are associated with the node you specify.

```
[-id <integer>] - Job ID
```

Use this parameter to display information only about the jobs that match the ID or range of IDs you specify.

```
[-vserver <vserver name>] - Owning Vserver
```

Use this parameter with the name of a Vserver to display only jobs that are owned by that Vserver.
[\[-name <text>] - Name
  Use this parameter to display information only about the jobs that match the job name you specify.

[\[-description <text>] - Description
  Use this parameter to display information only about the jobs that match the description you specify.

[\[-affinity {Cluster|Node}] - Affinity
  Use this parameter with an affinity value to display only jobs that match the affinity you specify.

[\[-username <text>] - User Name
  Use this parameter with a username to display only jobs that are associated with that user.

Examples
The following example displays information about all jobs on a per-node basis:

<table>
<thead>
<tr>
<th>Node</th>
<th>Job ID</th>
<th>Name</th>
<th>Vserver</th>
<th>Affinity</th>
</tr>
</thead>
<tbody>
<tr>
<td>node0</td>
<td>1501</td>
<td>log-rotation</td>
<td>node-vserver</td>
<td>Cluster</td>
</tr>
<tr>
<td>node1</td>
<td>1498</td>
<td>log-rotation</td>
<td>node-vserver</td>
<td>Cluster</td>
</tr>
<tr>
<td>node2</td>
<td>1499</td>
<td>log-rotation</td>
<td>node-vserver</td>
<td>Cluster</td>
</tr>
<tr>
<td>node3</td>
<td>1500</td>
<td>log-rotation</td>
<td>node-vserver</td>
<td>Cluster</td>
</tr>
</tbody>
</table>

\*job show-cluster*

Display a list of cluster jobs

**Availability:** This command is available to cluster and Vserver administrators at the admin privilege level.

**Description**

The job show-cluster command displays information about cluster-affiliated jobs. The command output depends on the parameters specified with the command. If no parameters are specified, the command displays information about all cluster-affiliated jobs.

To display detailed information about a specific job, run the command with the \-id parameter. The detailed view includes all of the default information plus additional items.

You can specify additional parameters to display only information that matches the values you specify for those parameters. For example, to display information only about jobs running on a specific node, run the command with the \-node parameter.

**Parameters**

\{\[-fields <fieldname>, ...\]
  If you specify the \-fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use \-fields ? to display the fields to specify.

\{|\[-instance\]}
  If you specify the \-instance parameter, the command displays detailed information about all fields.

[\[-id <integer>] - Job ID
  Use this parameter to display information only about the jobs that match the ID or range of IDs you specify.
[-vserver <vserver name>] - Owning Vserver
Use this parameter with the name of a Vserver to display only jobs that are owned by that Vserver.

[-name <text>] - Name
Use this parameter to display information only about the jobs that match the job name you specify.

[-description <text>] - Description
Use this parameter to display information only about the jobs that match the description you specify.

[-priority {Low|Medium|High|Exclusive}] - Priority
Use this parameter to display information only about the jobs that match the priority you specify.

[-node <nodename>] - Node
Use this parameter to display information only about the jobs that are associated with the node you specify.

[-affinity {Cluster|Node}] - Affinity
Use this parameter with an affinity value to display only jobs that match the affinity you specify.

[-schedule <job_schedule>] - Schedule
Use this parameter to display information only about the jobs that run on the schedule you specify.

[-queuetime <MM/DD HH:MM:SS>] - Queue Time
Use this parameter to display information only about the jobs that match the queue time you specify.

[-starttime <MM/DD HH:MM:SS>] - Start Time
Use this parameter to display information only about the jobs that match the start time you specify.

[-endtime <MM/DD HH:MM:SS>] - End Time
Use this parameter to display information only about the jobs that match the end time you specify.

[-dropdeadtime <MM/DD HH:MM:SS>] - Drop-dead Time
Use this parameter to display information only about the jobs that match the final timeout time you specify.

[-restarted {true|false}] - Restarted?
Use this parameter to display information only about the jobs that match the restart value you specify.

[-state {Initial|Queued|Running|Waiting|Pausing|Paused|Quitting|Success|Failure|Reschedule|Error|Quit|Dead|Unknown|Restart|Dormant}] - State
Use this parameter to display information only about the jobs that match the job state you specify.

[-code <integer>] - Status Code
Use this parameter to display information only about the jobs that match the status code you specify.

[-completion <text>] - Completion String
Use this parameter to display information only about the jobs that match the completion text you specify.

[-jobtype <text>] - Job Type
Use this parameter to display information only about the jobs that match the job type you specify.

[-category <text>] - Job Category
Use this parameter to display information only about the jobs that match the job category you specify.

[-uuid <UUID>] - UUID
Use this parameter to display information only about the jobs that match the UUID you specify.

[-username <text>] - User Name
Use this parameter with a username to display only jobs that are associated with the user you specify.

Examples
The following example displays information about all cluster-affiliated jobs:

---

RAW_TEXT_END
job show-completed

Display a list of completed jobs

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The job show-completed command displays information about completed jobs. The command output depends on the parameters you specify with the command. If you do not use any parameters, the command displays information about all completed jobs.

To display detailed information about a specific job, run the command with the -id parameter. The detailed view includes all of the default information plus additional items.

You can specify additional parameters to display only information that matches those parameters. For instance, to display information only about jobs running on a specific node, run the command with the -node parameter.

Parameters
{-fields <fieldname>,...}
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use -fields ? to display the fields to specify.

{-instance }
If you specify the -instance parameter, the command displays detailed information about all fields.

-id <integer> - Job ID
Use this parameter to display information only about the jobs that match the ID or range of IDs you specify.

-vserver <vserver name> - Owning Vserver
Use this parameter with the name of a Vserver to display only jobs that are owned by that Vserver.

-name <text> - Name
Use this parameter to display information only about the jobs that match the name you specify.

-description <text> - Description
Use this parameter to display information only about the jobs that match the description you specify.

-priority {Low|Medium|High|Exclusive} - Priority
Use this parameter to display information only about the jobs that match the priority you specify.
Use this parameter to display information only about the jobs that are associated with the node you specify.

Use this parameter with an affinity value to display only jobs that match the affinity you specify.

If you use this parameter, the command displays information only about the jobs that have the schedule you specify.

If you use this parameter, the command displays information only about the jobs that have the queue time you specify.

If you use this parameter, the command displays information only about the jobs that have the start time you specify.

Use this parameter to display information only about the jobs that have the end time you specify.

Use this parameter to display information only about the jobs that time out at the time you specify.

Use this parameter to display information only about the jobs that match the restart value you specify.

Use this parameter to display information only about the jobs that match the job state you specify.

Use this parameter to display information only about the jobs that match the status code you specify.

Use this parameter to display information only about the jobs that match the completion text you specify.

Use this parameter to display information only about the jobs that match the job type you specify.

Use this parameter to display information only about the jobs that match the job category you specify.

Use this parameter to display information only about the jobs that match the UUID you specify.

Use this parameter with a username to display only jobs that are associated with that user.

Examples
The following example displays information about all completed jobs:

```
node::> job show-completed
Owning Job ID Name            Vserver  End Time       Code       Completion String
------ --------------- -------- -------------- ---------- --------------------
305     Auto_Mirror    node-vserver 10/10 08:07:05 0  Succeeded
6202    mirror-03_10   node-vserver 10/10 11:10:07 0
6203    mirror-04_10   node-vserver 10/10 12:10:09 0
6204    mirror-01_10   node-vserver
```

Commands: Manual Page Reference
job stop

Stop a job

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The job stop command stops a running job. A stopped job cannot be resumed. Use the job pause command to pause a job so that you can later resume it. Use the job show command to view a list of running jobs.

Parameters
-id <integer> - Job ID
   The numeric ID of the job to stop. A job ID is a positive integer.

[-vserver <vserver name>] - Owning Vserver
   Use this parameter to specify the name of the Vserver that owns the job.

Examples
The following example stops the job that has ID 101:

   cluster1::> job stop -id 101

Related references
   job pause on page 141
   job show on page 142

job unclaim

Unclaim a cluster job

Availability: This command is available to cluster and Vserver administrators at the advanced privilege level.

Description
The job unclaim command causes a cluster-affiliated job that is owned by an unavailable node to be unclaimed by that node. Another node in the cluster can then take ownership of the job. Use the job show-cluster command to obtain a list of cluster-affiliated jobs.

Parameters
-id <integer> - Job ID
   Use this parameter to specify the ID number of the job to unclaim.

[-vserver <vserver name>] - Owning Vserver
   Use this parameter to specify the name of the Vserver that owns the job.
Examples
The following example shows how to unclaim the cluster-affiliated job with the ID 27 that is owned by the Vserver vs1:

```
cluster1::*> job unclaim -vserver vs1 -id 27
```

Related references

job show-cluster on page 145

job watch-progress

Watch the progress of a job

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The job watch-progress command displays the progress of a job, and periodically updates that display. You can specify the frequency of the updates.

Parameters
- **-id <integer>** - Job ID
  
  Use this parameter to specify the numeric ID of the job to monitor.

- **[-vserver <vserver name>]** - Owning Vserver
  
  Use this parameter to specify the name of the Vserver that owns the job.

- **[-interval <integer>]** - Refresh Interval (seconds)
  
  Use this parameter to specify the number of seconds between updates.

Examples
The following example show how to monitor the progress of the job that has ID 222 on Vserver vs0. The progress display updates every 3 seconds.

```
cluster1::> job watch-progress -vserver vs0 -id 222 -interval 3
```

job history commands

The history directory

job history show

Display a history of jobs

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The job history show command displays a history of completed jobs with newer entries displayed first. You can specify optional parameters to select information about job history items that match only those parameters. For example, to display information about jobs that were completed on February 27 at noon, run the command with -endtime "02/27 12:00:00".

Parameters

\{[-\textcolor{red}{\textit{fields}} <\textcolor{red}{\texttt{fieldname}}>, ...]

If you specify the \texttt{-fields <fieldname>}, ... parameter, the command output also includes the specified field or fields. You can use `-'-fields` to display the fields to specify.

\{[-\textcolor{red}{\textit{instance}} ]

If you specify the \texttt{-instance} parameter, the command displays detailed information about all fields.

\texttt{-node (<nodename>|local)} - Node

Selects the completed jobs that match this parameter value.

\texttt{-record <Sequence Number>} - Record ID

Selects the completed jobs that match the record ID or range of record IDs you specify. Note that record IDs are unique for each node, not for the cluster as a whole. As a result, there can be two records with the same record ID within the cluster.

\texttt{-vserver <vserver name>} - Owning Vserver

Selects the completed jobs that are owned by the Vserver you specify.

\texttt{-id <integer>} - Job ID

Selects the completed jobs that match this parameter value.

\texttt{-endtime <MM/DD HH:MM:SS>} - End Time

Selects jobs that completed at the time you specify. This parameter is most useful when used with a range of times.

\texttt{-starttime <MM/DD HH:MM:SS>} - Start Time

Selects completed jobs that were started at the time you specify. This parameter is most useful when used with a range of times.

\texttt{-name <text>} - Name

Selects the completed jobs that match this parameter value.

\texttt{-description <text>} - Description

Selects the completed jobs that match this parameter value.

\texttt{-code <integer>} - Status Code

Selects the completed jobs that match this parameter value. Each job defines its own status codes. The completion text is more informative, but support technicians may request this numeric code.

\texttt{-progress <text>} - Progress String

Selects the completed jobs that match this parameter value.

\texttt{-completion <text>} - Completion String

Selects the completed jobs that match this parameter value.

\texttt{-jobuuid <UUID>} - Job UUID (privilege: advanced)

Selects the completed jobs that match this parameter value.

\texttt{-event-type \{Idle|Running|Succeeded|Failed|Paused|Stopped|Deleted|Error\}} - Event Type

Selects the completed jobs that match this parameter value.

\texttt{-event-time <MM/DD HH:MM:SS>} - Event Time

Selects the completed jobs that match this parameter value. This parameter is most useful when used with a range of times.

\texttt{-error-code <integer>} - Job Manager Error Code

Selects the completed jobs that match this parameter value.
[-error-text <text>] - Job Manager Error Text
Selects the completed jobs that match this parameter value.

[-username <text>] - User Name
Selects the completed jobs that match this parameter value.

### Examples

The following example displays information about all completed jobs:

```
cluster1::> job history show
```

<table>
<thead>
<tr>
<th>Time</th>
<th>Node</th>
<th>Vserver</th>
<th>Name</th>
<th>Event</th>
<th>Job ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>08/23 08:58:24</td>
<td>node1</td>
<td>node1-vs</td>
<td>Vol Create</td>
<td>Succeeded</td>
<td>76</td>
</tr>
<tr>
<td>08/23 08:58:22</td>
<td>node1</td>
<td>node1-vs</td>
<td>Vol Create</td>
<td>Running</td>
<td>76</td>
</tr>
<tr>
<td>08/22 08:16:36</td>
<td>node1</td>
<td>node1-vs</td>
<td>CLUSTER BACKUP AUTO weekly</td>
<td>Succeeded</td>
<td>4</td>
</tr>
<tr>
<td>08/22 08:15:49</td>
<td>node1</td>
<td>node1-vs</td>
<td>CLUSTER BACKUP AUTO weekly</td>
<td>Running</td>
<td>4</td>
</tr>
<tr>
<td>08/22 08:15:03</td>
<td>node1</td>
<td>node1-vs</td>
<td>CLUSTER BACKUP AUTO weekly</td>
<td>Running</td>
<td>4</td>
</tr>
</tbody>
</table>

6 entries were displayed.

The following example shows how to use a range with the "endtime" parameter to select only the events that ended between 8:15 and 8:16 on August 22nd.

```
cluster1::> job history show -endtime "08/22 08:15:00".."08/22 08:16:00"
```

<table>
<thead>
<tr>
<th>Time</th>
<th>Node</th>
<th>Vserver</th>
<th>Name</th>
<th>Event</th>
<th>Job ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>08/22 08:15:49</td>
<td>node1</td>
<td>node1-vs</td>
<td>CLUSTER BACKUP AUTO weekly</td>
<td>Running</td>
<td>4</td>
</tr>
<tr>
<td>08/22 08:15:03</td>
<td>node1</td>
<td>node1-vs</td>
<td>CLUSTER BACKUP AUTO weekly</td>
<td>Running</td>
<td>4</td>
</tr>
</tbody>
</table>

3 entries were displayed.

### job initstate commands

Display the initialization state of job managers

### job initstate show

Display init state for job managers

**Availability:** This command is available to cluster administrators at the advanced privilege level.

**Description**

The job initstate show command displays information about the initialization states of job-manager processes.
Parameters
{ [-fields <fieldname>, ...] }  
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use -fields '?' to display the fields to specify.

[ -instance ]
If you specify the -instance parameter, the command displays detailed information about all fields.

[-node <nodename>|local] - Node
Selects the nodes that match this parameter value.

[-process <process_name>] - Process Name
Selects the nodes that match this parameter value.

[-initialized {true|false}] - Initialized?
Selects the nodes that match this parameter value (true means initialized; false means not initialized).

[-cache-root <text>] - Cache Root
Selects the nodes that match this parameter value.

[-siteid <UUID>] - Site ID
Selects the nodes that match this parameter value.

[-hp-threads <integer>] - High Priority Threads
Selects the nodes that have the number of high-priority threads you specify.

[-mp-threads <integer>] - Medium Priority Threads
Selects the nodes that have the number of medium-priority threads you specify.

[-lp-threads <integer>] - Low Priority Threads
Selects the nodes that have the number of low-priority threads you specify.

[-tx-interval <integer>] - Transaction Interval
Selects the nodes that have the number of seconds you specify as their transaction interval.

[-initmsg <text>] - Initialization Message
Selects the nodes that match this parameter value.

[-thread-initmsg <text>] - Thread Initialization Message
Selects the nodes that match this parameter value. The thread initialization message contains information about thread status. If there is no information to communicate, this message is empty.

[-recovery-enabled {true|false}] - Job Failover Enabled?
Selects the nodes that match this parameter value (true means enabled, false means not enabled).

[-ex-threads <integer>] - Exclusive Priority Threads
Selects the nodes that match this parameter value.

Examples
The following example shows how to display general job-manager initialization-state information for a cluster.

```
cluster1::*> job initstate show
<table>
<thead>
<tr>
<th>Node</th>
<th>Process</th>
<th>Init?</th>
<th>HP Thr</th>
<th>MP Thr</th>
<th>LP Thr</th>
<th>EX Thr</th>
<th>TX Int</th>
<th>Failover?</th>
</tr>
</thead>
<tbody>
<tr>
<td>node1</td>
<td>mgwd</td>
<td>true</td>
<td>2</td>
<td>3</td>
<td>5</td>
<td>8</td>
<td>300</td>
<td>true</td>
</tr>
<tr>
<td>node2</td>
<td>mgwd</td>
<td>true</td>
<td>2</td>
<td>3</td>
<td>5</td>
<td>8</td>
<td>300</td>
<td>true</td>
</tr>
</tbody>
</table>
2 entries were displayed.
```

job initstate commands 153
The following example shows how to display detailed job-manager initialization-state information for a node named node0.

```
cluster1::*> job initstate show -instance -node node0
  Node: node0
  Process Name: mgwd
  Initialized?: true
  Cache Root: /mroot/jm_cache
  Site ID: 824e8f7d-f49-1d9-84af-00423b7352
  High Priority Threads: 2
  Medium Priority Threads: 3
  Low Priority Threads: 5
  Transaction Interval: 300
  Initialization Message: Initialized
  Are Threads Running?: -
  Job Failover Enabled?: true
  Exclusive Priority Threads: 8
```

### job private commands

Manage private jobs

#### job private delete

Delete a job

**Availability:** This command is available to cluster and Vserver administrators at the advanced privilege level.

**Description**

The job private delete command deletes a private job. Private jobs are affiliated with a specific node and do not use any cluster facilities, such as the replicated database.

If you use this command on a job that does not support the delete operation, the command returns an error message.

Use the job private show command to view a list of private jobs that can be deleted.

**Parameters**

- **-node** `<nodename>|local>` - Node
  
  Use this parameter to specify the node with which the private job is associated.

- **-id** `<integer>` - Job ID
  
  Use this parameter to specify the numeric ID of the private job to be deleted. A job ID is a positive integer.

- **[ -vserver `<vserver name>` ]** - Owning Vserver
  
  Use this parameter to specify the name of the Vserver that owns the job.

**Examples**

The following example shows how to delete the job that has ID 273 from the node named node2:

```
cluster1::*> job private delete -node node2 -id 273
```

**Related references**

*job private show* on page 156
**job private pause**

Pause a job

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *advanced* privilege level.

**Description**
The `job private pause` command pauses a private job. Private jobs are affiliated with a specific node and do not use any cluster facilities, such as the replicated database.

If you use this command to pause a job that does not support it, the command returns an error message.

Use the `job private resume` command to resume a paused private job.

Use the `job private show` command to view a list of private jobs.

**Parameters**
- `-node` `<nodename>|local` - *Node*
  
  Use this parameter to specify the node with which the private job is associated.

- `-id` `<integer>` - *Job ID*
  
  Use this parameter to specify the numeric ID of the paused private job to be paused. A job ID is a positive integer.

- `[-vserver `<vserver name>`]` - *Owning Vserver*
  
  Use this parameter to specify the name of the Vserver that owns the job.

**Examples**
The following example pauses the private job that has ID **99** on the node **node1**:  

```bash
cluster1::*> jobs private pause -node node1 -id 99
```

**Related references**
- `job private resume` on page 155
- `job private show` on page 156

---

**job private resume**

Resume a job

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *advanced* privilege level.

**Description**
The `job private resume` command resumes a private job that was paused by using the `job private pause` command. Private jobs are affiliated with a specific node and do not use any cluster facilities, such as the replicated database.

Use the `job private show` command to view a list of paused private jobs that can be resumed.

**Parameters**
- `-node` `<nodename>|local` - *Node*
  
  Use this parameter to specify the node with which the paused private job is associated.

- `-id` `<integer>` - *Job ID*
  
  Use this parameter to specify the numeric ID of the paused private job to be resumed. A job ID is a positive integer.
[-vserver <vserver name>] - Owning Vserver

Use this parameter to specify the name of the Vserver that owns the job.

Examples

The following example resumes the paused private job that has ID 99 on a node named node2:

cluster1::*> job private resume -node node2 -id 99

Related references

job private pause on page 155
job private show on page 156

job private show

Display a list of jobs

Availability: This command is available to cluster and Vserver administrators at the advanced privilege level.

Description

The job private show command displays information about private jobs. Private jobs are affiliated with a specific node and do not use any cluster facilities, such as the replicated database.

Parameters

{ [...] }  
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

[-inprogress ]  
Displays the job ID, name, owning Vserver, and progress of each private job.

[-jobstate ]  
Displays information about each private job's state, including the queue state, whether the job was restarted, and when the job has timed out.

[-jobuuid ]  
Displays the ID, name, owning Vserver, and UUID of each private job.

[-sched ]  
Displays the job ID, name, owning Vserver, and run schedule of each private job.

[-times ]  
Displays the queue time, start time, and end time of each private job.

[-type ]  
Displays the type and category of each private job.

[-instance ]]  
If you specify the -instance parameter, the command displays detailed information about all fields.

[-node {<nodename> | local}] - Node

Selects the private jobs that match this parameter value.

[-id <integer>] - Job ID

Selects the private jobs that match the ID or range of IDs that you specify.
[-vserver <vserver name>] - Owning Vserver
   Selects the private jobs that match this parameter value.
[-name <text>] - Name
   Selects the private jobs that match this parameter value.
[-description <text>] - Description
   Selects the private jobs that match this parameter value.
[-priority {Low|Medium|High|Exclusive}] - Priority
   Selects the private jobs that match this parameter value.
[-schedule <job_schedule>] - Schedule
   Selects the private jobs that match this parameter value.
[-queuetime <MM/DD HH:MM:SS>] - Queue Time
   Selects the private jobs that match this parameter value.
[-starttime <MM/DD HH:MM:SS>] - Start Time
   Selects the private jobs that match this parameter value.
[-endtime <MM/DD HH:MM:SS>] - End Time
   Selects the private jobs that match this parameter value.
[-dropdeadtime <MM/DD HH:MM:SS>] - Drop-dead Time
   Selects the private jobs that match this parameter value.
[-restarted {true|false}] - Restarted?
   Selects the private jobs that match this parameter value.
[-state {Initial|Queued|Running|Waiting|Pausing|Paused|Quitting|Success|Failure|Reschedule|Error|Quit|Dead|Unknown|Restart|Dormant}] - State
   Selects the private jobs that match this parameter value.
[-code <integer>] - Status Code
   Selects the private jobs that match this parameter value.
[-completion <text>] - Completion String
   Selects the private jobs that match this parameter value.
[-jobtype <text>] - Job Type
   Selects the private jobs that match this parameter value.
[-category <text>] - Job Category
   Selects the private jobs that match this parameter value.
[-uuid <UUID>] - UUID
   Selects the private jobs that match this parameter value.
[-progress <text>] - Execution Progress
   Selects the private jobs that match this parameter value.
[-username <text>] - User Name
   Selects the private jobs that match this parameter value.

Examples
   The following example displays information about all private jobs on the local node:
job private show-completed

Display a list of completed jobs

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *advanced* privilege level.

**Description**
The `job private show-completed` command displays information about completed private jobs. Private jobs are affiliated with a specific node and do not use any cluster facilities, such as the replicated database.

**Parameters**

```
[-fields <fieldname>, ...]  # If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

[-instance]]  # If you specify the -instance parameter, the command displays detailed information about all fields.

[-node {<nodename>|local}]- Node  # Use this parameter to display information only about completed jobs that are associated with the node you specify.

[-id <integer>]- Job ID  # Use this parameter to display information only about completed jobs that have the ID you specify.

[-vserver <vserver name>]- Owning Vserver  # Use this parameter to display only completed jobs that are owned by the Vserver you specify.

[-name <text>]- Name  # Use this parameter to display information only about completed jobs that have the name you specify.

[-description <text>]- Description  # Use this parameter to display information only about completed jobs that have the description you specify.

[-priority {Low|Medium|High|Exclusive}]- Priority  # Use this parameter to display information only about completed jobs that have the priority you specify.

[-schedule <job_schedule>]- Schedule  # Use this parameter to display information only about completed jobs that have the schedule you specify.

[-queuetime <MM/DD HH:MM:SS>]- Queue Time  # Use this parameter to display information only about completed jobs that have the queue time you specify.
```
[-starttime &lt;MM/DD HH:MM:SS&gt;] - Start Time
Use this parameter to display information only about completed jobs that have the start time you specify.

[-endtime &lt;MM/DD HH:MM:SS&gt;] - End Time
Use this parameter to display information only about completed jobs that have the end time you specify.

[-dropdeadtime &lt;MM/DD HH:MM:SS&gt;] - Drop-dead Time
Use this parameter to display information only about completed jobs that have the final timeout time you specify.

[-restarted {true|false}] - Restarted?
Use this parameter to display information only about completed jobs that have the restart value you specify.

[-state {Initial|Queued|Running|Waiting|Pausing|Paused|Quitting|Success|Failure|Reschedule|Error|Quit|Dead|Unknown|Restart|Dormant}] - State
Use this parameter to display information only about completed jobs that have the job state you specify.

[-code &lt;integer&gt;] - Status Code
Use this parameter to display information only about completed jobs that have the status code you specify.

[-completion &lt;text&gt;] - Completion String
Use this parameter to display information only about completed jobs that have the completion text you specify.

[-jobtype &lt;text&gt;] - Job Type
Use this parameter to display information only about completed jobs that have the job type you specify.

[-category &lt;text&gt;] - Job Category
Use this parameter to display information only about completed jobs that have the job category you specify.

[-uuid &lt;UUID&gt;] - UUID
Use this parameter to display information only about completed jobs that have the UUID you specify.

[-username &lt;text&gt;] - User Name
Use this parameter to display information only about completed jobs that are associated with the user you specify.

Examples
The following example shows how to display information about all completed private jobs on the node named node1:

```
cluster1::* job private show-completed -node node1
Node: node1

Owning Job ID Name     Vserver   End Time     Code      Completion String
------ -------------- --------- -------------- ------- ---------------------
1       sync task     node1      02/17 15:03:23 0     DONE_VIF_STATS
2       load_balancing node1      02/17 16:29:28 0     DONE_VIF_STATS
3       snap-hourly   node1      02/17 16:05:00 0
4       snap-daily    node1      02/17 00:10:00 0
5       snap-weekly   node1      02/13 00:15:00 0
6       Cross-Cluster Manager node1 02/17 16:27:27 0     complete
7       reconcile service policy node1 02/17 15:03:12 0
7 entries were displayed.
```

job private stop
Stop a job

Availability: This command is available to cluster and Vserver administrators at the advanced privilege level.
Description
The `job private stop` command stops a running private job. A private job is a job that is associated with a specific node and does not use cluster facilities. A stopped job cannot be restarted.

Parameters

- `-node <nodename> | local` - Node
  This specifies the node on which the job is running.

- `-id <integer>` - Job ID
  This specifies the numeric ID of the job that is to be stopped.

- `[-vserver <vserver name>]` - Owning Vserver
  Use this parameter to specify the name of the Vserver that owns the job.

Examples

The following example stops a private job with the ID 416 on a node named node0:

```
class1:*> job private stop -node node0 -id 416
```

**job private watch-progress**

Watch the progress of a job

**Availability:** This command is available to `cluster` and `Vserver` administrators at the `advanced` privilege level.

Description

The `job private watch-progress` command displays and periodically updates the progress of a private job. A private job is a job that is associated with a specific node and does not use cluster facilities. You can specify the frequency of the progress updates.

Parameters

- `-node <nodename> | local` - Node
  This specifies the node on which the job is running.

- `-id <integer>` - Job ID
  This specifies the numeric ID of the job whose progress is to be monitored.

- `[-vserver <vserver name>]` - Owning Vserver
  Use this parameter to specify the Vserver with which the paused private job is associated. Use this parameter to specify the name of the Vserver that owns the job.

- `[-interval <integer>]` - Refresh Interval (seconds)
  This optionally specifies, in seconds, the frequency of the updates.

Examples

The following example monitors the progress of the private job that has ID 127 on a node named node1. The progress is updated every 2 seconds.

```
class1:*> job private watch-progress -node node1 -id 127 -interval 2
```

Queued
job schedule commands

Manage job schedules

job schedule delete

Delete a schedule

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The job schedule delete command deletes a schedule. Use the job schedule show command to display all current schedules.

You cannot delete any schedules that are in use by jobs. Use the job schedule show-jobs command to display jobs by schedule.

You cannot delete any schedules that are referenced by:

- Volume Snapshot copy policy entries
- SnapMirror entries
- SIS policy entries
- configuration backup settings

You must remove all references to a schedule before you can delete it. If you attempt to delete a schedule that is referenced, an error message will list which entries reference the schedule you want to delete. Use the show command for each of the items listed by the error message to display which entries reference the schedule. You may need to use the -instance parameter to display more detail.

Parameters

[-cluster <Cluster name>] - Cluster
This parameter specifies the name of the cluster on which you want to delete a schedule. By default, the schedule is deleted from the local cluster. In a MetroCluster configuration, the partner cluster can be specified if the local cluster is in switchover state.

-name <text> - Schedule Name
Use this parameter with the name of an existing schedule to specify the schedule you want to delete.

Examples

The following example deletes a schedule named overnightbackup:

```
cluster1::> job schedule delete -name overnightbackup
```

Related references

- job schedule show on page 162
- job schedule show-jobs on page 162
**job schedule show**

Display a list of available schedules

**Availability:** This command is available to _cluster_ and _Vserver_ administrators at the _admin_ privilege level.

**Description**
The `job schedule show` command displays information about schedules.

**Parameters**

{ [-fields <fieldname>, ...]
  If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

[-instance ]
  If you specify the `-instance` parameter, the command displays detailed information about all fields.

[-cluster <Cluster name>] - Cluster
  Selects the schedules that match this parameter value.

[-name <text>] - Schedule Name
  Selects the schedules that match this parameter value.

[-type {cron|interval|builtin}] - Schedule Type
  Selects the schedules that match this parameter value.

[-description <text>] - Description
  Selects the schedules that match this parameter value.

**Examples**
The following example displays information about all schedules:

```
cluster1::> job schedule show
Cluster       Name         Type     Description
------------- ----------- --------- -------------------------------------------
cluster1       5min        cron      0:00,:05,:10,:15,:20,:25,:30,:35,:40,:45,:50,:55
cluster1       daily       cron      00:10
cluster1       hourly      cron      0:05
cluster1       monthly    cron      1@0:20
cluster1       weekly     cron      Sun@0:15
```

**job schedule show-jobs**

Display the list of jobs by schedule

**Availability:** This command is available to _cluster_ administrators at the _admin_ privilege level.

**Description**
The `job schedule show-jobs` command displays information about jobs that are associated with schedules.

**Parameters**

{ [-fields <fieldname>, ...]
  If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.
If you specify the \texttt{-instance} parameter, the command displays detailed information about all fields.

\textbf{\texttt{-name <text>}} - Schedule Name

Use this parameter to display information only about the jobs that are associated with the schedule you specify.

\textbf{\texttt{-affinity \{Cluster|Node\} }} - Cluster / Node

Use this parameter to display information only about the jobs that match the affinity value you specify.

\textbf{\texttt{-owner <text>}} - Owner

Use this parameter to display information only about the jobs that are owned by the nodes you specify.

\textbf{\texttt{-jobid <integer>}} - ID

Use this parameter to display information only about the jobs that match the ID or range of IDs that you specify.

\textbf{\texttt{-jobname <text>}} - Job Name

Use this parameter to display information only about the jobs that match the name you specify.

\textbf{Examples}

The following example shows information about schedules that are associated with jobs:

```
cluster1::> job schedule show-jobs
Name          Type      Owner                  Job ID     Job Name
------------  --------- ---------------------  ---------- --------------------
hourly        Cluster   -                      98644      mirror-hourly
weeklylog     Node      node0                  1501       log-rotation
weeklylog     Node      node1                  1498       log-rotation
weeklylog     Node      node2                  1499       log-rotation
weeklylog     Node      node3                  1500       log-rotation
```

\textbf{5 entries were displayed.}

\textbf{job schedule cron commands}

Manage cron-type job schedules

\textbf{job schedule cron create}

Create a cron schedule

\textbf{Availability:} This command is available to \textit{cluster} and \textit{Vserver} administrators at the \textit{admin} privilege level.

\textbf{Description}

The \textit{job schedule cron create} command creates a cron schedule. A cron schedule, like a UNIX cron job, runs at a specified time. You can also specify months, days of the month, or days of the week on which the schedule will run.

If you specify values for both days of the month and days of the week, they are considered independently. For example, a cron schedule with the day specification Friday, 13 runs every Friday and on the 13th day of each month, not just on every Friday the 13th.

\textbf{Parameters}

\textbf{\texttt{[-cluster <Cluster name>]} - Cluster}

This parameter specifies the name of the cluster on which you want to create a cron schedule. By default, the schedule is created on the local cluster. In a MetroCluster configuration, the partner cluster can be specified if the local cluster is in switchover state.
- **Name**: Use this parameter to specify the name of the cron schedule that you want to create.

- **Month**: Use this parameter to specify months in which the schedule runs. Valid values are January, February, March, April, May, June, July, August, September, October, November, December, and all. Specify "all" to run the schedule every month.

- **Day of Week**: Use this parameter to specify days of the week on which the schedule runs. Valid values are Sunday, Monday, Tuesday, Thursday, Friday, and Saturday, and all. Specify "all" to run the schedule every day.

- **Day**: Use this parameter to specify days of the month on which the schedule runs. Valid values range from 1 to 31.

- **Hour**: Use this parameter to specify the hours value of the time of day at which the schedule runs. Valid values range from 0 (midnight) to 23 (11:00 p.m.). Specify "all" to run the schedule every hour.

- **Minute**: Use this parameter to specify the minutes portion of the time of day at which the schedule runs. Valid values range from 0 to 59.

**Examples**

The following example creates a cron schedule named weekendcron that runs on weekend days (Saturday and Sunday) at 3:00 a.m.

```
cluster1::> job schedule cron create -name weekendcron -dayofweek "Saturday, Sunday" -hour 3 -minute 0
```

**job schedule cron delete**

Delete a cron schedule

**Availability**: This command is available to cluster and Vserver administrators at the admin privilege level.

**Description**

The job schedule cron delete command deletes a cron schedule. Use the job schedule cron show command to display all current cron schedules.

You cannot delete any cron schedules that are associated with jobs. Use the job schedule show-jobs command to display jobs by schedule.

**Parameters**

- **Cluster**: This parameter specifies the name of the cluster on which you want to delete a cron schedule. By default, the schedule is deleted from the local cluster. In a MetroCluster configuration, the partner cluster can be specified if the local cluster is in switchover state.

- **Name**: Use this parameter with the name of an existing cron schedule to specify the cron schedule that you want to delete.

**Examples**

The following example deletes a cron schedule named midnightcron:

```
cluster1::> job schedule cron delete -name midnightcron
```
The `job schedule cron modify` command modifies a cron schedule. A cron schedule, like a UNIX cron job, runs at a specified time. You can also specify months, days of the month, or days of the week on which the schedule runs. Use the `job schedule cron show` command to display all current cron schedules. See the documentation for `job schedule cron show` for more information about how cron schedules work.

Modifying one parameter of a cron schedule does not affect the other parameters. For example, if cron schedule is set to run at 3:15 AM, and you modify the "hour" parameter to 4, the schedule's new time will be 4:15am. To clear a parameter of the schedule's interval, you must explicitly set that portion to "0" or "." Some parameters can also be set to "all".

**Parameters**

[-cluster <Cluster name>] - Cluster

Use this parameter to specify the cluster of an existing cron schedule you want to modify. The local cluster is provided as the default value. In a MetroCluster configuration, the partner cluster can be specified if the local cluster is in switchover state.

-name <text> - Name

Use this parameter with the name of an existing cron schedule to specify the cron schedule you want to modify.

[-month <cron_month>, ...] - Month

Use this parameter to specify a new "month" value for the cron schedule. Valid values are January, February, March, April, May, June, July, August, September, October, November, December, or all. Specify "all" to run the schedule every month.

[-dayofweek <cron_dayofweek>, ...] - Day of Week

Use this parameter to specify a new "day of week" value for the cron schedule. Valid values include Sunday, Monday, Tuesday, Thursday, Friday, Saturday, or all. Specify "all" to run the schedule every day.

[-day <cron_dayofmonth>, ...] - Day

Use this parameter to specify a new "day of month" value for the cron schedule. Valid values range from 1 to 31.

[-hour <cron_hour>, ...] - Hour

Use this parameter to specify a new "hour of the day" value for the cron schedule. Valid values range from 0 (midnight) to 23 (11:00 p.m.), Specify "all" to run the schedule every hour.

[-minute <cron_minute>, ...] - Minute

Use this parameter to specify a new "minute of the hour" value for the cron schedule. Valid values range from 0 to 59.

**Examples**

The following example modifies a cron schedule named weekendcron so that it runs at 3:15 a.m.:
Related references

`job schedule cron show` on page 166

**job schedule cron show**

Show cron schedules

**Availability:** This command is available to `cluster` and `Vserver` administrators at the `admin` privilege level.

**Description**

The `job schedule cron show` command displays information about cron schedules. A cron schedule runs a job at a specified time on specified days.

**Parameters**

`[ [-fields <fieldname>, ...]`

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

`| [-instance ]]`

If you specify the `-instance` parameter, the command displays detailed information about all fields.

`[-cluster <Cluster name>] - Cluster`

Selects the cron schedules that match this parameter value.

`[-name <text>] - Name`

Selects the cron schedules that match this parameter value.

`[-month <cron_month>, ...] - Month`

Selects the cron schedules that match this parameter value. Valid values are `January`, `February`, `March`, `April`, `May`, `June`, `July`, `August`, `September`, `October`, `November`, `December`, or `all`.

`[-dayofweek <cron_dayofweek>, ...] - Day of Week`

Selects the cron schedules that match this parameter value. Valid values include `Sunday`, `Monday`, `Tuesday`, `Wednesday`, `Thursday`, `Friday`, `Saturday`, or `all`.

`[-day <cron_dayofmonth>, ...] - Day`

Selects the cron schedules that match this parameter value. Valid values range from `1` to `31`.

`[-hour <cron_hour>, ...] - Hour`

Selects the cron schedules that match this parameter value.

`[-minute <cron_minute>, ...] - Minute`

Selects the cron schedules that match the minute or range of minutes that you specify.

`[-description <text>] - Description`

Selects the cron schedules that match this parameter value.

**Examples**

The following example displays information about all current cron schedules:
### job schedule interval commands

Manage interval-based job schedules

#### job schedule interval create

Create a schedule that runs on an interval

**Availability:** This command is available to cluster and Vserver administrators at the admin privilege level.

**Description**

The `job schedule interval create` creates an interval schedule. An interval schedule runs jobs at specified intervals after the previous job finishes. For instance, if a job uses an interval schedule of 12 hours and takes 30 minutes to complete, the job runs at the following times:

- Day one at 8:00 a.m. (the job's initial run)
- Day one at 8:30 p.m.
- Day two at 9:00 a.m.
- Day two at 9:30 p.m.

Each of the numerical parameters of the interval must be a whole number. These parameters can be used individually, or combined to define complex time values. For example, use a value of 1 day, 12 hours to create an interval of 1.5 days.

Large parameter values are converted into larger units. For example, if you create a schedule with an interval of 36 hours, the `job schedule interval show` command will display it with an interval of 1 day 12 hours.

**Parameters**

- `-cluster <Cluster name>` - Cluster
  
  This parameter specifies the name of the cluster on which you want to create an interval schedule. By default, the schedule is created on the local cluster. In a MetroCluster configuration, the partner cluster can be specified if the local cluster is in switchover state.

- `-name <text>` - Name
  
  Use this parameter to specify the name of the interval schedule you want to create.

- `-days <integer>` - Days
  
  Use this parameter to specify the "days" portion of the schedule's interval. A day is one calendar day.
[-hours <integer>] - Hours
Use this parameter to specify the "hours" portion of the schedule's interval.

[-minutes <integer>] - Minutes
Use this parameter to specify the "minutes" portion of the schedule's interval.

[-seconds <integer>] - Seconds
Use this parameter to specify the "seconds" portion of the schedule's interval.

Examples
The following example creates an interval schedule named rollingdaily that runs six hours after the completion of the previous occurrence of the job:

```
cluster1::> job schedule interval create -name rollingdaily -hours 6
```

Related references
job schedule interval show on page 169

job schedule interval delete
Delete an interval schedule

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The job schedule interval delete command deletes an interval schedule. Use the job schedule interval show command to display all current interval schedules.

You cannot delete interval schedules that are currently being run. Use the job schedule show-jobs command to display jobs by schedule.

Parameters
[-cluster <Cluster name>] - Cluster
This parameter specifies the name of the cluster on which you want to delete an interval schedule. By default, the schedule is deleted from the local cluster. In a MetroCluster configuration, the partner cluster can be specified if the local cluster is in switchover state.

-name <text> - Name
Use this parameter with the name of an existing interval schedule to specify the interval schedule you want to delete.

Examples
The following example deletes an interval schedule named rollingdaily:

```
cluster1::> job schedule interval delete -name rollingdaily
```

Related references
job schedule interval show on page 169
job schedule show-jobs on page 162
job schedule interval modify

Modify an interval schedule

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The job schedule interval modify command modifies an interval schedule. An interval schedule runs jobs at a specified interval after the previous job finishes. Use the job schedule interval show command to display all current interval schedules. See the documentation of job schedule interval show for more information on how interval schedules work.

Modifying one parameter of a schedule’s interval does not affect the other parameters. For example, if a schedule's interval is 1 day 12 hours, and you modify the "hours" parameter to 16, the schedule's new interval is 1 day 16 hours. To clear a parameter of the schedule's interval, you must explicitly set that parameter to "0" or "-".

Parameters

[-cluster <Cluster name>] - Cluster
Use this parameter to specify the cluster of an existing interval schedule you want to modify. The local cluster is provided as the default value. In a MetroCluster configuration, the partner cluster can be specified if the local cluster is in switchover state.

-name <text> - Name
Use this parameter with the name of an existing interval schedule to specify the interval schedule you want to modify.

[-days <integer>] - Days
Use this parameter to specify a different "days" value for the schedule's interval.

[-hours <integer>] - Hours
Use this parameter to specify a different "hours" value for the schedule's interval.

[-minutes <integer>] - Minutes
Use this parameter to specify a different "minutes" value for the schedule's interval.

[-seconds <integer>] - Seconds
Use this parameter to specify a different "seconds" value for the schedule's interval.

Examples
The following example sets the schedule named rollingdaily to run every eight hours:

cluster1:~> job schedule interval modify -name rollingdaily -hours 8

Related references
job schedule interval show on page 169

job schedule interval show
Show interval schedules

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The job schedule interval show command displays information about interval schedules.
Parameters

\{-fields <fieldname>, ...\}

If you specify the \{-fields <fieldname>, ...\} parameter, the command output also includes the specified field or fields. You can use \{-fields ?\} to display the fields to specify.

\{-instance\}

If you specify the \{-instance\} parameter, the command displays detailed information about all fields.

\{-cluster <Cluster name>\} - Cluster

Selects the interval schedules that match this parameter value.

\{-name <text>\} - Name

Selects the interval schedules that match this parameter value.

\{-days <integer>\} - Days

Selects the interval schedules that match the day value or range of values you specify.

\{-hours <integer>\} - Hours

Selects the interval schedules that match the hour value or range of values you specify.

\{-minutes <integer>\} - Minutes

Selects the interval schedules that match the minute value or range of values you specify.

\{-seconds <integer>\} - Seconds

Selects the interval schedules that match the second value or range of values you specify.

\{-description <text>\} - Description

Selects the interval schedules that match the description you specify.

Examples

The following example displays information about all interval schedules:

```
cluster1::> job schedule interval show
Cluster       Name        Description
------------- ----------- ---------------------------------------------------------------------
ccluster1     rollingdaily Every 8h
```

lun commands

Manage LUNs

lun create

Create a new LUN

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description

This command creates a new LUN of a specific size. You cannot create a LUN at a path that already exists. You must create LUNs at the root of a volume or qtree. You cannot create LUNs in the Vserver root volume.
You might find it useful to provide a meaningful path name for the LUN and containing volume. For example, you might choose a name that describes how the LUN is used, such as the name of the application, the type of data that it stores, or the user accessing the data. Examples are /vol/database/lun0, /vol/finance/lun1, and /vol/bill/lun2.

It is recommended that you distribute LUNs across the cluster.

When you can create a LUN, the size of the LUN could be larger than what you specified. The system generates a message if the size of the LUN is different from what you specified.

By default, when you create a LUN, it is online and it is space-reserved. Use the `lun offline` command to take a LUN offline. When you set space reserved to false, the LUN is non-space reserved.

**Note:** For non-space reserved LUNs, write operations to that LUN might fail due to insufficient disk space. As a result, the host application or operating system might crash.

**Note:** When you create a LUN from a file, that file cannot be deleted without deleting the LUN itself.

**Parameters**

- `-vserver <Vserver Name>` - Vserver Name
  Specifies the Vserver.

- `{ -path <path> }` - LUN Path
  Specifies the path of the new LUN. The LUN path cannot contain any files. Examples of correct LUN paths are `/vol/vol1/lun1` and `/vol/vol1/qtree1/lun1`.

- `| -volume <volume name>` - Volume Name
  Specifies the volume that contains the new LUN.

- `[-qtree <qtree name>]` - Qtree Name
  Specifies the qtree that contains the new LUN.

- `-lun <text>` - LUN Name
  Specifies the new LUN name. A LUN name is a case-sensitive name and has the following requirements:
  - Must contain one to 255 characters. Spaces are not allowed.
  - Can contain the letters A-Z, a-z, numbers 0-9, ",", ",", ",", ",", ",", and ",, and ",,.

- `{ -size | -s <size> }` - LUN Size
  Specifies the size of the LUN in bytes. You can specify a one-character multiplier suffix:
  - c (1 byte)
  - w (2 bytes)
  - B (512 bytes)
  - k (1024 bytes)
  - M (k*k bytes)
  - G (k*m bytes)
  - T (m*m bytes)

- `[-use-exact-size [true]]` - Use Exact Size (privilege: advanced)
  Create the LUN using the exact value specified by the `-size` parameter instead of rounding the size to best fit the LUN geometry. Size of the LUN must be a multiple of 512 bytes.

- `|-file-path | -f <text>` - File Path
  Creates a LUN using the file path as the source.
-foreign-disk - Foreign Disk Serial number (privilege: advanced)

LUN is created with the same attributes (size, alignment, bytes per sector and so on) as the specified foreign disk.

-prefix-size -P <size> - Prefix Size (privilege: advanced)

Specifies the size of the prefix stream for the new LUN.

-ostype -t {vmware|hyper_v|windows_2008|windows_gpt|windows|linux|xen|solaris|solaris_efi|hpux|aix|netware|openvms} - OS Type

Specifies the OS type for the new LUN. The OS types are:

- aix - the LUN stores AIX data.
- hpux - the LUN stores HP-UX data.
- hyper_v - the LUN stores Windows Server 2008 or Windows Server 2012 Hyper-V data
- linux - the LUN stores a Linux raw disk without a partition table.
- netware - the LUN stores NetWare data.
- openvms - the LUN stores Open-VMS data
- solaris - the LUN stores Solaris raw disk in a single-slice partition.
- solaris_efi - the LUN stores Solaris_EFI data.
- vmware - the LUN stores VMware data
- windows - the LUN stores a raw disk type in a single-partition Windows disk using the Master Boot Record (MBR) partitioning style.
- windows_gpt - the LUN stores Windows data using the GUID Partition Type (GPT) partitioning style.
- windows_2008 - the LUN stores Windows data for Windows 2008 or later systems.
- xen - the LUN stores Xen data

-space-reserve {enabled|disabled} - Space Reservation

Specifies whether the space reservation setting is enabled or disabled for the new LUN. If you set the parameter to enabled, the LUN is space-reserved. If you set the parameter to disabled, the LUN is non-space reserved. The default is enabled.

-comment <text> - Comment

A description for the LUN you want to create. If the comment string contains white space, you must enclose the comment string in double quotes. The limit is 254 characters.

-space-allocation {enabled|disabled} - Space Allocation

Specifies the value for the space allocation attribute of the LUN. The space allocation attribute determines if the LUN supports the SCSI Thin Provisioning features defined in the Logical Block Provisioning section of the SCSI SBC-3 standard.

Specifying enabled for this parameter enables support for the SCSI Thin Provisioning features.
Specifying disabled for this parameter disables support for the SCSI Thin Provisioning features.
Hosts and file systems that do not support SCSI Thin Provisioning should not enable space allocation.
The default is disabled.

-class {regular|protocol-endpoint|vvol} - Class

Specifies the class of the new LUN. The class types are:
• regular - the LUN is for normal blocks protocol access. This is the default value.
• protocol-endpoint - the LUN is a vvol protocol endpoint.
• vvol - the LUN is a vvol data LUN.

{ [-qos-policy-group <text>] - QoS Policy Group
  This optionally specifies which QoS policy group to apply to the LUN. This policy group defines measurable
  service level objectives (SLOs) that apply to the storage objects with which the policy group is associated. If
  you do not assign a policy group to a LUN, the system will not monitor and control the traffic to it.
  
  Note: If you specify this parameter for a LUN that you want to create from a file and that file belongs to a
  QoS policy group, Data ONTAP adds the LUN to the specified policy group and removes the file from its
  policy group. Both the file and the LUN that you created from the file cannot belong to QoS policy groups.

[[-qos-adaptive-policy-group <text>]] - QoS Adaptive Policy Group
  This optionally specifies which QoS adaptive policy group to apply to the LUN. This policy group defines
  measurable service level objectives (SLOs) and service level agreements (SLAs) that adjust based on the
  LUN's allocated space or used space.

[-caching-policy <text>] - Caching Policy Name
  This optionally specifies the caching policy to apply to the LUN. A caching policy defines how the system
  caches this volume's data in Flash Cache modules. If a caching policy is not assigned to this LUN, the system
  uses the caching policy that is assigned to the containing volume or Vserver. If a caching policy is not assigned
  to the containing volume or Vserver, the system uses the default cluster-wide policy. The available caching
  policies are:
  • none - Does not cache any user data or metadata blocks.
  • auto - Read caches all metadata and randomly read user data blocks, and write caches all randomly
    overwritten user data blocks.
  • meta - Read caches only metadata blocks.
  • random_read - Read caches all metadata and randomly read user data blocks.
  • random_read_write - Read caches all metadata, randomly read and randomly written user data blocks.
  • all_read - Read caches all metadata, randomly read and sequentially read user data blocks.
  • all_read_random_write - Read caches all metadata, randomly read, sequentially read, and randomly written
    user data.
  • all - Read caches all data blocks read and written. It does not do any write caching.
  
  Default caching-policy is auto.

Examples

cluster1::> lun create -vserver vs1 -path /vol/vol1/lun1 -size 100M -ostype linux

lun delete

Delete the LUN

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.
Description
This command deletes a LUN from a specified Vserver and volume. If the LUN is mapped and online, the force option is
required to delete it.

If a LUN is mapped to an initiator group, you can unmap it by using the `lun unmap` command. If a LUN is online, you take it
offline by using the `lun offline` command.

Note: If you create a LUN from a file, you cannot remove the file while the LUN is linked to it. If you want to remove the
file, you must first delete the LUN.

Parameters
- `vserver <Vserver Name>` - Vserver Name
  Specifies the Vserver.

  \{ -path `<path>` - LUN Path
  Specifies the path of the LUN you want to delete. Examples of correct LUN paths are `/vol/vol1/lun1`
  and `/vol/vol1/qtree1/lun1`.

  | -volume `<volume name>` - Volume Name
  Specifies the volume that contains the LUN you want to delete.

  | -qtree `<qtree name>` - Qtree Name
  Specifies the qtree that contains the LUN you want to delete.

  | -lun `<text>` - LUN Name
  Specifies the LUN that you want to delete.

  | -force | -f [true] - Force Deletion of an Online and Mapped LUN
  Force deletion of an online LUN that is mapped to an initiator group.

  | -force-fenced [true] - Force Deletion of a Fenced LUN
  Force deletion of a LUN that is currently fenced.

Examples
```
cluster1::> lun delete -vserver vs1 -path /vol/vol1/lun1
```

Related references
`lun mapping delete` on page 212

lun maxsize
Display the maximum possible size of a LUN on a given volume or qtree.

Availability: This command is available to `cluster` and `Vserver` administrators at the `admin` privilege level.

Description
This command returns the maximum size of LUNs for different OS types in a volume or qtree. The command also includes
possible maximum size for LUNs with Snapshots or without Snapshots. You can specify the path of the volume or qtree to
determine the maximum size of a LUN that you want to create within that volume or qtree.

If you do not specify a path, the command returns the maximum LUN size for each OS type for all volumes and qtrees in a
cluster.

The available space in a volume can change over time which means that the size reported by `lun maxsize` can change as well.
In addition, the maximum LUN size allowed in a `lun resize` command may be less than the size reported by `lun maxsize`.
Parameters

```{-fields <fieldname>, ...}
If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.
```

```{-instance}
If you specify the `-instance` parameter, the command displays detailed information about all fields.
```

```{-vserver <Vserver Name>}] - Vserver Name
Specifies the Vserver.
```

```{-path <qtree path>}] - Volume or Qtree Path
Specifies the path of the root volume or qtree. Examples of correct LUN paths are `/vol/vol1/lun1` and `/vol/vol1/qtree1/lun1.
```

```{-volume <volume name>}] - Volume Name
Specifies the volume that contains the LUN you want to get the maximum size for.
```

```{-qtree <qtree name>}] - Qtree Name
Specifies the qtree that contains the LUN you want to get the maximum size for.
```

```{-ostype | -t {vmware|hyper_v|windows_2008|windows_gpt|windows|linux|xen|solaris|solaris_efi|hpux|aix|netware|openvms}] - OS Type
Specifies OS type of the LUN. The OS types are:
• aix - the LUN stores AIX data.
• hpux - the LUN stores HP-UX data.
• hyper_v - the LUN stores Windows Server 2008 or Windows Server 2012 Hyper-V data
• linux - the LUN stores a Linux raw disk without a partition table.
• netware - the LUN stores NetWare data.
• openvms - the LUN stores Open-VMS data
• solaris - the LUN stores Solaris raw disk in a single-slice partition.
• solaris_efi - the LUN stores Solaris_EFI data.
• vmware - the LUN stores VMware data
• windows - the LUN stores a raw disk type in a single-partition Windows disk using the Master Boot Record (MBR) partitioning style.
• windows_gpt - the LUN stores Windows data using the GUID Partition Type (GPT) partitioning style.
• windows_2008 - the LUN stores Windows data for Windows 2008 or later systems.
• xen - the LUN stores Xen data
```

```{-complete-ss-reserve <size>}] - With Complete Snapshot Reserve
Shows the maximum size possible of a LUN if you have the complete Snapshot reserve enabled.
```

```{-ss-reserve <size>}] - With Snapshot Reserve
Shows the maximum size possible of a LUN if you have the Snapshot reserve enabled.
```

```{-without-ss-reserve <size>}] - Without Snapshot Reserve
Shows the maximum size possible of a LUN if you have no Snapshot reserve enabled.
```
Examples

```
cluster1::> lun maxsize -volume vol0 -ostype netware

<table>
<thead>
<tr>
<th>Virtual Server</th>
<th>Volume</th>
<th>Qtree</th>
<th>OS Type</th>
<th>Without SS Reserve</th>
<th>With SS Reserve</th>

`lun resize` on page 180

**lun modify**

Modify a LUN

**Availability:** This command is available to `cluster` and `Vserver` administrators at the `admin` privilege level.

**Description**

This command modifies LUN attributes. Because LUN modifications can result in data corruption or other problems, we recommend that you call technical support if you are unsure of the possible consequences of modifying a LUN.

**Parameters**

- `vserver <Vserver Name>` - Vserver Name
  
  Specifies the Vserver.

- `{ -path <path> }` - LUN Path

  Specifies the path for the LUN you want to modify. Examples of correct LUN paths are `/vol/vol1/lun1` and `/vol/vol1/qtree1/lun1`.

- `| -volume <volume name>` - Volume Name

  Specifies the volume for the LUN you want to modify.

- `| -qtree <qtree name>` - Qtree Name

  Specifies the qtree for the LUN you want to modify.

- `| -lun <text>}` - LUN Name

  Specifies the name for the LUN you want to modify. A LUN name is a case-sensitive name and has the following requirements:
Must contain one to 255 characters. Spaces are not allowed.

Can contain the letters A through Z, a through z, numbers 0 through 9, hyphen (-), underscore (_), right bracket (}), left bracket (() and period (.).

Must start with a letter or number.

[-space-reserve {enabled|disabled}] - Space Reservation

Specifies whether the space reservation setting is enabled or disabled for a LUN. If you set the parameter to enabled, the LUN is space-reserved. If you set the parameter to disabled, the LUN is non-space reserved. The default is enabled.

{ [-serial <text>] - Serial Number

Specifies the serial number for the LUN you want to modify.

The LUN serial number is a twelve-character alphanumeric string containing one or more of the following:

- upper- and lower-case letters
- numbers
- the characters: &<>, /, =, @, [ ] , ^, ~

Some of the characters that are valid in a LUN serial number also have special meaning to the cluster shell command line:

- The question mark (?) activates the command line active help. In order to type a question mark as part of a LUN's serial number, it is necessary to disable active help with the command set -active-help false. Active help can later be re-enabled with the command set -active-help true.

- The number sign (#) indicates the beginning of a comment to the command line and will cause the remainder of the line to be ignored. To avoid this, enclose the serial number in double quotes (").

Alternatively, the -serial-hex parameter can be used to set the LUN serial number specifying the serial number encoded in hexadecimal form.

[ [-serial-hex <Hex String>] - Serial Number (Hex)

Specifies the serial number, encoded in hexadecimal form, for the LUN you want to modify. See the description of the -serial parameter for additional details.

[-comment <text>] - Comment

Specifies the comment for the LUN you want to modify.

[-space-allocation {enabled|disabled}] - Space Allocation

Specifies the new value for the space allocation attribute of the LUN. The space allocation attribute determines if the LUN supports the SCSI Thin Provisioning features defined in the Logical Block Provisioning section of the SCSI SBC-3 standard.

Specifying enabled for this parameter enables support for the SCSI Thin Provisioning features.

Specifying disabled for this parameter disables support for the SCSI Thin Provisioning features.

Hosts and file systems that do not support SCSI Thin Provisioning should not enable space allocation.

[-state {online|offline|nvfail|space-error|foreign-lun-error}] - State

Specifies the administrative state of a LUN. The options are:

- online
- offline
[-device-legacy-id <integer>] - Device Legacy ID
  Specifies the device legacy ID for the LUN you want to modify.

[-device-binary-id <text>] - Device Binary ID
  Specifies the device binary ID for the LUN you want to modify.

[-clear-binary-id [true]] - Clear Device Binary ID
  Clears the binary format of the optional device ID.

[-device-text-id <text>] - Device Text ID
  Specifies the device text ID for the LUN you want to modify.

[-clear-text-id [true]] - Clear Device Text ID
  Clears the text format of the optional device ID.

[-qos-policy-group <text>] - QoS Policy Group
  This optionally specifies which QoS policy group to apply to the lun. This policy group defines measurable service level objectives (SLOs) that apply to the storage objects with which the policy group is associated. If you do not assign a policy group to a lun, the system will not monitor and control the traffic to it. To remove this lun from a policy group, enter the reserved keyword "none".

[-qos-adaptive-policy-group <text>] - QoS Adaptive Policy Group
  This optional parameter specifies which QoS adaptive policy group to apply to the LUN. This policy group defines measurable service level objectives (SLOs) and Service Level Agreements (SLAs) that adjust based on the LUN's allocated space or used space. To remove this LUN from an adaptive policy group, enter the reserved keyword "none".

[-caching-policy <text>] - Caching Policy Name
  This optionally specifies the caching policy to apply to the LUN. A caching policy defines how the system caches this volume's data in Flash Cache modules. If a caching policy is not assigned to this LUN, the system uses the caching policy that is assigned to the containing volume or Vserver. If a caching policy is not assigned to the containing volume or Vserver, the system uses the default cluster-wide policy. The available caching policies are:
  • none - Does not cache any user data or metadata blocks.
  • auto - Read caches all metadata and randomly read user data blocks, and write caches all randomly overwritten user data blocks.
  • meta - Read caches only metadata blocks.
  • random_read - Read caches all metadata and randomly read user data blocks.
  • random_read_write - Read caches all metadata, randomly read and randomly written user data blocks.
  • all_read - Read caches all metadata, randomly read and sequentially read user data blocks.
  • all_read_random_write - Read caches all metadata, randomly read, sequentially read, and randomly written user data.
  • all - Read caches all data blocks read and written. It does not do any write caching.

Default caching-policy is auto.

**Examples**

```
cluster1::> lun modify -path /vol/vol1/lun1 -space-reserve disable
```

Disables the space reserve attribute for LUN /vol/vol1/lun1.
lun move-in-volume

Move a LUN within a volume

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

**Description**
This command moves a LUN to a new path in the same volume or renames a LUN. If you are organizing LUNs in a qtree, the command moves a LUN from one qtree to another. You can perform a LUN move while the LUN is online and serving data. The process is non-disruptive. Use the `lun move start` command to move a LUN to a different volume within the same *Vserver*.

**Parameters**
- `vserver <Vserver Name>` - Vserver Name
  Specifies the *Vserver*.

  { -path <path> - LUN Path
    Specifies the path of the LUN you want to move. Examples of correct LUN paths are `/vol/vol1/lun1` and `/vol/vol1/qtree1/lun1`.

  | -volume <volume name> - Volume Name
    Specifies the volume of the LUN you want to move.

  | -qtree <qtree name> - Qtree Name
    Specifies the qtree of the LUN you want to move.

  -lun <text> - LUN Name
    Specifies the name of the LUN that you want to move.

  { -new-path <path> - New LUN Path
    Specifies the new path of the LUN. Examples of correct LUN paths are `/vol/vol1/lun1` and `/vol/vol1/qtree1/lun1`.

  | [-new-qtree <qtree name>] - New Qtree Name
    Specifies the new qtree name that you want to move the LUN to.

  -new-lun <text> - New LUN Name
    Specifies the new name of the LUN.

**Examples**

```
cluster1::> lun move-in-volume -vserver vs1 -volume voll -lun lun1 -new-lun newlun1
```

Renames *lun1* to *newlun1* on *Vserver* *vs1* and volume *voll*.

lun move start on page 220

lun resize

Changes the size of the LUN to the input value size.

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
This command resizes a LUN. You can resize a LUN that is mapped and online. However, to prevent any potential problems, take the LUN offline before resizing it.

When you reduce the size of the LUN, the data in the LUN could be truncated. You will receive an error message if you reduce the size of the LUN. To avoid this error message, use the force parameter.

When you increase the size of a LUN, the maximum resize size is based on the initial geometry of the LUN and the currently available space in the volume. You will receive an error message if you exceed this limit. The lun show -instance command reports the “Maximum Resize Size” for a LUN based on the initial geometry. The lun maxsize command reports the maximum LUN size based on the available space. The maximum size of the LUN is the smaller of the two limits issued by the lun show -instance command or the lun maxsize command.

Parameters
- `vserver <Vserver Name>` - Vserver Name
  Specifies the Vserver.

  `{ -path <path> }` - LUN Path
  Specifies the path of the LUN that you want to resize. Examples of correct LUN paths are /vol/vol1/lun1 and /vol/vol1/qtree1/lun1.

  `| -volume <volume name>` - Volume Name
  Specifies the volume that contains the LUN that you want to resize.

  [ -qtree <qtree name> ]` - Qtree Name
  Specifies the qtree that contains the LUN that you want to resize.

  `-lun <text>` - LUN Name
  Specifies the LUN name that you want to resize.

  Overrides any warnings if you are reducing the size of the LUN. If you use this parameter without a value, it is set to true, and the command does not prompt you when reducing the size of a LUN would produce warnings. If you do not use this parameter, the command displays an error if reducing the size of a LUN would create a problem.

  `-size <size>` - New Size
  Specifies the new size of the LUN.
  • c (1 byte)
- w (2 bytes)
- B (512 bytes)
- k (1024 bytes)
- M (k*k bytes)
- G (k*m bytes)
- T (m*m bytes)

### Examples

```
cluster1::> lun resize -vserver vs1 -path /vol/vol1/lun1 -size 500M -force
```

Resizes LUN /vol/vol1/lun1 on Vserver vs1 to 500M, overriding all warnings.

```
cluster1::> lun resize -vserver vs1 -path /vol/vol1/lun1 -size +5m
```

```
Vserver Path State Mapped Type Size
--------- -------------------- ------- -------- -------- --------
vs1 /vol/vol1/lun1 online mapped linux 15MB
```

Adds 5M of space to LUN /vol/vol1/lun1 for a total of 15MB.

```
cluster1::> lun resize -vserver vs1 -path /vol/vol1/lun1 -size -10m
```

Error: command failed: Reducing LUN size without coordination with the host system may cause permanent data loss or corruption. Use the force flag to allow LUN size reduction.

```
cluster1::> lun resize -path /vol/vol1/lun1 -size -5m -f
```

```
Vserver Path State Mapped Type Size
--------- -------------------- ------- -------- -------- --------
vs1 /vol/vol1/lun1 online mapped linux 10MB
```

## lun show

Display a list of LUNs

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

**Description**
The command displays information for LUNs. Use the **instance** parameter to display additional LUN details, such as serial number and space-reservation settings.
Parameters

{[-fields <fieldname>, ...]

If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

[-instance ]

If you specify the -instance parameter, the command displays detailed information about all fields.

[-vserver <Vserver Name>] - Vserver Name

Selects the LUNs that match this parameter value.

{ [-path <path>] - LUN Path

Selects the LUNs that match this parameter value. Examples of correct LUN paths are /vol/vol1/lun1 and /vol/vol1/qtree1/lun1

[-volume <volume name>] - Volume Name

Selects the LUNs that match this parameter value.

[-qtree <qtree name>] - Qtree Name

Selects the LUNs that match this parameter value.

[-lun <text>] - LUN Name

Selects the LUNs that match this parameter value.

[-size | -s <size>] - LUN Size

Selects the LUNs that match this parameter value.

[-prefix-size | -P <size>] - Prefix Size (privilege: advanced)

Selects the LUNs that match the prefix stream size that you specify.

[-ostype | -t {vmware|hyper_v|windows_2008|windows_gpt|windows|linux|xen|solaris|solaris_efi|hpux|aix|netware|openvms}] - OS Type

Selects the LUNs that match this parameter value. The operating system types are:

- **aix** - the LUN stores AIX data.
- **hpux** - the LUN stores HP-UX data.
- **hyper_v** - the LUN stores Windows Server 2008 or Windows Server 2012 Hyper-V data
- **linux** - the LUN stores a Linux raw disk without a partition table.
- **netware** - the LUN stores NetWare data.
- **openvms** - the LUN stores Open-VMS data
- **solaris** - the LUN stores Solaris raw disk in a single-slice partition.
- **solaris_efi** - the LUN stores Solaris_EFI data.
- **vmware** - the LUN stores VMware data
- **windows** - the LUN stores a raw disk type in a single-partition Windows disk using the Master Boot Record (MBR) partitioning style.
- **windows_gpt** - the LUN stores Windows data using the GUID Partition Type (GPT) partitioning style.
- **windows_2008** - the LUN stores Windows data for Windows 2008 or later systems.
- **xen** - the LUN stores Xen data
[-space-reserve {enabled|disabled}] - Space Reservation

Selects the LUNs that match this parameter value. A value of enabled selects LUN that are space-reserved. A value of disabled select LUNs that are non-space reserved.

[-serial <text>] - Serial Number

Selects the LUNs that match this parameter value.

The LUN serial number is a twelve-character alphanumeric string containing one or more of the following:

- upper- and lower-case letters
- numbers
- the characters: &<, >, /, -, #, $, %, *, +, =, ?, @, [, ], ^, ~

Some of the characters that are valid in a LUN serial number also have special meaning to the cluster shell command:

- The question mark (?) activates the command line active help. In order to type a question mark as part of a LUN's serial number, it is necessary to disable active help with the command set -active-help false. Active help can later be re-enabled with the command set -active-help true.
- The number sign (#) indicates the beginning of a comment to the command line and will cause the remainder of the line to be ignored. To avoid this, enclose the serial number in double quotes ("").
- The less than (<), greater than (>), asterisk (*), and exclamation point (!) influence the query behavior of the command. To use these as characters in a LUN's serial query, you must first press escape (ESC). To use these characters to influence the query, enclose the serial number, or partial serial number, in double quotes ("") and apply <, >, *, or !, outside of the double quotes.

Alternatively, the -serial-hex parameter can be used to select LUNs using the serial number encoded in hexadecimal form.

[-serial-hex <Hex String>] - Serial Number (Hex)

Selects the LUNs that match this parameter value. This parameter applies to the LUN serial number encoded in hexadecimal form. See the description of the -serial parameter for additional details.

[-comment <text>] - Comment

Selects the LUNs that match this parameter value.

[-space-reserve-honored {true|false}] - Space Reservations Honored

Selects the LUNs that match this parameter value. A value of true select LUNs that have their space reservation honored by the container volume. A value of false displays the LUNs that are non-space reserved.

[-space-allocation {enabled|disabled}] - Space Allocation

Selects the LUNs that match this parameter value. The space allocation attribute determines if the LUN supports the SCSI Thin Provisioning features defined in the Logical Block Provisioning section of the SCSI SBC-3 standard.

Specifying enabled for this parameter selects LUNs with support enabled for the SCSI Thin Provisioning features.

Specifying disabled for this parameter selects LUNs with support disabled for the SCSI Thin Provisioning features.

Hosts and file systems that do not support SCSI Thin Provisioning should not enable space allocation.

[-container-state {online|aggregate-offline|volume-offline|error}] - LUN Container State

Selects the LUNs that match this parameter value. The container states are:
• **online** - The LUN's aggregate and volume are online.
• **aggregate-offline** - The LUN's aggregate is offline.
• **volume-offline** - The LUN's volume is offline.
• **error** - An error occurred accessing the LUN's volume.

```
[-state {online|offline|nvfail|space-error|foreign-lun-error}] - State
```
Selects the LUNs that match this parameter value. The states are:

• **online** - The LUN is online.
• **offline** - The LUN is administratively offline, or a more detailed offline reason is not available.
• **foreign-lun-error** - The LUN has been automatically taken offline due to a media error on the associated foreign LUN.
• **nvfail** - The LUN has been automatically taken offline due to an NVRAM failure.
• **space-error** - The LUN has been automatically taken offline due to insufficient space.

```
[-uuid <UUID>] - LUN UUID
```
Selects the LUNs that match this parameter value.

```
[-mapped {mapped|unmapped}] - Mapped
```
Selects the LUNs that match this parameter value. A value of mapped selects the LUNs that are mapped to an initiator group.

```
[-block-size {512|4KB}] - Physical Size of Logical Block
```
Selects the LUNs that match this parameter value.

```
[-device-legacy-id <integer>] - Device Legacy ID
```
Selects the LUNs that match this parameter value.

```
[-device-binary-id <text>] - Device Binary ID
```
Selects the LUNs that match this parameter value.

```
[-device-text-id <text>] - Device Text ID
```
Selects the LUNs that match this parameter value.

```
[-read-only {true|false}] - Read Only
```
Selects the LUNs that match this parameter value.

```
[-restore-inaccessible {true|false}] - Fenced Due to Restore
```
Selects the LUNs that match the state you specify. A value of true means that a LUN is fenced for I/O and management due to a restore operation.

```
[-size-used <size>] - Used Size
```
Selects the LUNs that match this parameter value.

```
[-max-resize-size <size>] - Maximum Resize Size
```
Selects the LUNs that match this parameter value.

```
[-creation-timestamp <MM/DD/YYYY HH:MM:SS>] - Creation Time
```
Selects the LUNs that match this parameter value.

```
[-class {regular|protocol-endpoint|vvol}] - Class
```
Selects the LUNs that match this parameter value.

```
[-node <nodename>] - Node Hosting the LUN
```
Selects the LUNs that match this parameter value.
[-qos-policy-group <text>] - QoS Policy Group
Selects the LUNs that match this parameter value.
A policy group defines measurable service level objectives (SLOs) that apply to the storage objects with which the policy group is associated. If you do not assign a policy group to a LUN, the system will not monitor and control the traffic to it.

[-qos-adaptive-policy-group <text>] - QoS Adaptive Policy Group
Selects the LUNs that match this parameter value.
An adaptive policy group defines measurable service level objectives (SLOs) that apply to the storage objects with which the adaptive policy group is associated.

[-caching-policy <text>] - Caching Policy Name
Display the LUNs that match the specified cache.
A caching policy defines the caching behavior of this LUN at the Flash Cache level. If a caching policy is not assigned to this LUN, the system uses the caching policy that is assigned to the containing volume or Vserver. If a caching policy is not assigned to the containing volume or Vserver, the system uses the default cluster-wide policy. The available caching policies are:

- none - Does not cache any user data or metadata blocks.
- auto - Read caches all metadata and randomly read user data blocks, and write caches all randomly overwritten user data blocks.
- meta - Read caches only metadata blocks.
- random_read - Read caches all metadata and randomly read user data blocks.
- random_read_write - Read caches all metadata, randomly read and randomly written user data blocks.
- all_read - Read caches all metadata, randomly read and sequentially read user data blocks.
- all_read_random_write - Read caches all metadata, randomly read, sequentially read, and randomly written user data.
- all - Read caches all data blocks read and written. It does not do any write caching.

Default caching-policy is auto.

[-is-clone {true|false}] - Clone
Selects the LUNs that match this parameter value.

[-is-clone-autodelete-enabled {true|false}] - Clone Autodelete Enabled
Selects the LUNs that match this parameter value.

[-inconsistent-import {true|false}] - Inconsistent Import
Selects the LUNs that match this parameter value. A value of true means that the import of this LUN is incomplete.

[-serial-7-mode <text>] - 7-mode Serial Number (privilege: advanced)
Selects the LUNs that match this parameter value.
LUNs transitioned from Data ONTAP 7-Mode are assigned new serial numbers for use with Clustered Data ONTAP. The original 7-Mode serial number is displayed in this field for reference.

[-application <text>] - Application
Selects the LUNs that are part of an application that matches the parameter value.
[-include-offline-containers [true]] - Include LUNs on Offline Volumes and Aggregates (privilege: advanced)

If true, include available information for LUNs in offline aggregates and offline volumes in the output. By default, LUNs in offline aggregates and offline volumes are excluded from the output.

Examples

The following example displays details of the LUN at path /vol/vol1/lun1 in Vserver vs1.

```
cluster1::> lun show -vserver vs1 -path /vol/vol1/lun1 -instance
Vserver Name: vs1
LUN Path: /vol/vol1/lun1
Volume Name: vol1
Qtree Name: 
LUN Name: lun1
LUN Size: 10MB
OS Type: linux
Space Reservation: disabled
Serial Number: wCVt1jIlvQWv
Serial Number (Hex): 77435674315d496c76515776
Comment: new comment
Space Reservations Honored: false
Space Allocation: disabled
State: offline
LUN UUID: 76d2eba4-dd3f-494c-ad63-1995c1574753
Mapped: mapped
Block Size: 512
Device Legacy ID: -
Device Binary ID: -
Device Text ID: -
Read Only: false
Fenced Due to Restore: false
Used Size: 5MB
Maximum Resize Size: 64.00GB
Creation Time: 9/14/2016 13:55:09
Class: regular
Node Hosting the LUN: node1
QoS Policy Group: -
Caching Policy Name: -
Clone: false
Clone Autodelete Enabled: false
Inconsistent Import: false
Application: -
```

The following example displays information for the LUN with serial number 1r/wc+9Cpbls:

```
cluster1::> lun show -serial 1r/wc+9Cpbls
Vserver   Path                            State   Mapped   Type        Size
--------- ------------------------------- ------- -------- -------- --------
vs1       /vol/vol2/lun1                  online  mapped   linux        10MB
```

The following example displays all the LUNs on Vserver vs1 and volume vol1:

```
cluster1::> lun show -vserver vs1 -volume vol1
Vserver   Path                            State   Mapped   Type        Size
--------- ------------------------------- ------- -------- -------- --------
vs1       /vol/vol1/lun1                  offline mapped linux  10MB
vs1       /vol/vol1/lun2                  online  mapped windows 47.07MB
2 entries were displayed.
```

lun bind commands

The bind directory
**lun bind create**

Bind a VVol LUN to a protocol endpoint

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *advanced* privilege level.

**Description**

This command creates a new binding between a protocol endpoint and a vvol LUN. If a binding between the specified endpoint and vvol already exists, the reference count for the binding is incremented by one.

**Note:** For optimal results, the protocol endpoint and vvol must be hosted by the same node in the cluster.

**Parameters**

- `vserver <Vserver Name>` - *Vserver name*
  
  Specifies the name of the Vserver.

- `protocol-endpoint-path <path>` - *Protocol Endpoint*
  
  Specifies the path to the protocol endpoint. The specified LUN must already exist and be of class "protocol-endpoint". Examples of correct LUN paths are `/vol/vol1/lun1` and `/vol/vol1/qtrees/lun1`.

- `vvol-path <path>` - *VVol Path*
  
  Specifies the path to the vvol. The specified LUN must already exist and be of the class "vvol". Examples of correct LUN paths are `/vol/vol1/lun1` and `/vol/vol1/qtrees/lun1`.

**Examples**

```
cluster1:*> lun bind create -vserver vs1 -protocol-endpoint-path /vol/VV1/PE1 -vvol-path /vol/VV3/234ace
```

**lun bind destroy**

Unbind a VVol LUN from a protocol endpoint

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *advanced* privilege level.

**Description**

Decrement the reference count of the binding between a protocol endpoint and vvol LUN. If the resulting reference count is zero, the binding is removed.

**Parameters**

- `vserver <Vserver Name>` - *Vserver name*
  
  Specifies the Vserver.

- `protocol-endpoint-path <path>` - *Protocol Endpoint*
  
  Specifies the path of the protocol endpoint LUN. Examples of correct LUN paths are `/vol/vol1/lun1` and `/vol/vol1/qtrees/lun1`.

- `vvol-path <path>` - *VVol Path*
  
  Specifies the path of the vvol LUN. Examples of correct LUN paths are `/vol/vol1/lun1` and `/vol/vol1/qtrees/lun1`.

  **[-force [true]]** - If true, unbind the Vvol completely even if the current reference count is greater than 1. The default is false.

  Completely remove the specified binding, regardless of the current reference count.
### lun bind show

Show list of Vvol bindings

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *advanced* privilege level.

**Description**

Shows the configured VVol to protocol endpoint bindings.

**Parameters**

{[-fields <fieldname>, ...]
   If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

[-instance]
   If you specify the `-instance` parameter, the command displays detailed information about all fields.

[-vserver <Vserver Name>] - Vserver Name
   Selects the bindings that match this parameter value.

[-protocol-endpoint-msid <integer>] - PE MSID
   Selects the bindings that match this parameter value.

[-protocol-endpoint-vdisk-id <text>] - PE Vdisk ID
   Selects the bindings that match this parameter value.

[-vvol-msid <integer>] - VVol MSID
   Selects the bindings that match this parameter value.

[-vvol-vdisk-id <text>] - VVol Vdisk ID
   Selects the bindings that match this parameter value.

[-vserver-uuid <UUID>] - Vserver UUID
   Selects the bindings that match this parameter value.

[-protocol-endpoint-path <path>] - Protocol Endpoint
   Selects the bindings that match this parameter value. Examples of correct LUN paths are `/vol/vol1/lun1` and `/vol/vol1/qtree1/lun1.`

[-protocol-endpoint-node <nodename>] - PE Node
   Selects the bindings that match this parameter value.

[-vvol-path <path>] - VVol
   Selects the bindings that match this parameter value. Examples of correct LUN paths are `/vol/vol1/lun1` and `/vol/vol1/qtree1/lun1.`

[-vvol-node <nodename>] - VVol Node
   Selects the bindings that match this parameter value.

[-secondary-lun <Hex 64bit Integer>] - Secondary LUN
   Selects the bindings that match this parameter value.
[-is-optimal (true|false)] - Optimal binding
Selects the bindings that match this parameter value.

[-reference-count <integer>] - Reference Count
Selects the bindings that match this parameter value.

Examples

```
cluster1:*> lun bind show -vserver vs1
Vserver   Protocol Endpoint      Vvol LUN  Node     Secondary LUN  Optimal?
---------- ------------------------ ---------- --------- -------------- --------
vs1       /vol/VV1/PE1           d20000010000 false
          /vol/VV2/30dfab         d20000020000 true
          /vol/VV3/234ace        d20000030000 true
          /vol/VV2/PE2           cluster-node2
          /vol/VV2/30dfab         d20000010000 true
4 entries were displayed.
```

Manage Lun Copy Operations

Manage LUN copy operations

lun copy cancel

Cancel a LUN copy operation before the new LUN has been created

Availability: This command is available to cluster and Vserver administrators at the advanced privilege level.

Description
The lun copy cancel command cancels an ongoing LUN copy operation prior to creation of the new LUN. The command fails if the LUN already exists at the destination path; in that case, use the lun delete command to delete the LUN at the destination path.

All data transfers will be halted.

Note: This is an advanced command because the preferred way to cancel a LUN copy operation is to wait until the new LUN becomes visible, and then use the lun delete command to delete the LUN.

Parameters

- [-vserver <Vserver Name>] - Vserver Name
  Specifies the name of the Vserver that will host the destination LUN.

- [-destination-path <path>] - Destination Path
  Specifies the full path to the new LUN, in the format /vol/<volume>/<qtree>/<lun>.

Examples

```
cluster1:*> lun copy cancel -vserver vs1 -destination-path /vol/vol2/lun2
```

Related references

lun delete on page 173
**lun copy modify**

Modify an ongoing LUN copy operation

*Availability:* This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

**Description**

The `lun copy modify` command modifies the maximum throughput of an ongoing copy operation.

**Parameters**

- `-vserver <Vserver Name>` - *Vserver Name*
  
  Specifies the name of the Vserver that will host the destination LUN.

- `-destination-path <path>` - *Destination Path*
  
  Specifies the full path to the new LUN, in the format `/vol/<volume>[/<qtree>]/<lun>`.

- `-max-throughput <integer>{KB|MB|GB|TB|PB}` - *Maximum Transfer Rate (per sec)*
  
  Specifies the maximum amount of data, in bytes, that can be transferred per second in support of this operation. This mechanism can be used to throttle a transfer, to reduce its impact on the performance of the source and destination nodes.

  **Note:** The specified value will be rounded up to the nearest megabyte.

**Examples**

```
cluster1::> lun copy modify -vserver vs1 -destination-path /vol/vol2/lun2 -max-throughput 25MB
```

**lun copy pause**

Pause an ongoing LUN copy operation

*Availability:* This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

**Description**

The `lun copy pause` command pauses an ongoing copy operation. Use the `lun copy resume` command to resume the copy operation.

**Parameters**

- `-vserver <Vserver Name>` - *Vserver Name*
  
  Specifies the name of the Vserver that will host the destination LUN.

- `-destination-path <path>` - *Destination Path*
  
  Specifies the full path to the new LUN, in the format `/vol/<volume>[/<qtree>]/<lun>`.

**Examples**

```
cluster1::> lun copy pause -vserver vs1 -destination-path /vol/vol2/lun2
```

**Related references**

`lun copy resume` on page 191
lun copy resume

Resume a paused LUN copy operation

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The lun copy resume command resumes a paused copy operation.

Parameters

{-vserver <Vserver Name> - Vserver Name
   Specifies the name of the Vserver that will host the destination LUN.

-destination-path <path> - Destination Path
   Specifies the full path to the new LUN, in the format /vol/<volume>[/<qtree>]/<lun>.

Examples

cluster1::> lun copy resume -vserver vs1 -destination-path /vol/vol2/lun2

Related references
lun copy pause on page 190

lun copy show

Display a list of LUNs currently being copied

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The lun copy show command shows information about LUNs currently being copied in the cluster.

Parameters

[{[-fields <fieldname>, ...]
   If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use `-fields ?' to display the fields to specify.

[-instance ]
   If you specify the -instance parameter, the command displays detailed information about all fields.

[-vserver <Vserver Name>] - Destination Vserver Name
   Selects LUN copy operations that match this parameter value.

[-destination-path <path>] - Destination Path
   Selects LUN copy operations that match this parameter value.

[-source-vserver <vserver name>] - Source Vserver Name
   Selects LUN copy operations that match this parameter value.

[-source-path <path>] - Source Path
   Selects LUN copy operations that match this parameter value.

[-source-snapshot <snapshot name>] - Source Snapshot Name
   Selects LUN copy operations that match this parameter value.
[-is-promoted-early {true|false}] - Is Destination Promoted Early
Selects LUN copy operations that match this parameter value.

[-max-throughput {<integer>[KB|MB|GB|TB|PB]}] - Maximum Transfer Rate (per sec)
Selects LUN copy operations that match this parameter value.

[-job-status {Preparing|Allocation-Map|Data|Destroying|Paused-Admin|Paused-Error|Complete|Destroyed}] - LUN Copy Status
Selects LUN copy operations that match this parameter value. The possible values are:

- **Preparing** - the LUN copy job is in Preparing status.
- **Allocation-Map** - the LUN copy job is in Allocating status.
- **Data** - the LUN copy job is in Moving Data status.
- **Destroying** - the LUN copy job is in Destroying status.
- **Paused-Admin** - the LUN copy job is in Paused By Admin status.
- **Paused-Error** - the LUN copy job is in Paused By Error status.
- **Complete** - the LUN copy job is in Complete status.
- **Destroyed** - the LUN copy job is in Destroyed status.

[-progress-percent <percent>] - LUN Copy Progress (%)
Selects LUN copy operations that match this parameter value.

[-elapsed-time <time_interval>] - Elapsed Time
Selects LUN copy operations that match this parameter value.

[-cutover-time <time_interval>] - Cutover Time
Selects LUN copy operations that match this parameter value.

[-is-snapshot-fenced {true|false}] - Is Snapshot Fenced
Selects LUN copy operations that match this parameter value.

[-is-destination-ready {true|false}] - Is Destination Ready
Selects LUN copy operations that match this parameter value.

[-last-failure-reason <text>] - Last Failure Reason
Selects LUN copy operations that match this parameter value.

### Examples

```
cluster1::> lun copy show
Vserver       Destination Path  Status       Progress
------------- ------------------ ------------------------
vs1           /vol/vol2/lun1    Data          35%
vs1           /vol/vol2/lun2    Complete     100%
2 entries were displayed.
```

The example above displays information about all the LUN copy operations in the cluster.

```
cluster1::> lun copy show -vserver vs1 -destination-path /vol/vol2/lun1 -instance

Destination Vserver Name: vs1
Destination Path: /vol/vol2/lun1
Source Vserver Name: vs1
Source Path: /vol/vol1/lun1
Source Snapshot Name: -
Is Destination Promoted Early: false
```
lun copy start

Start copying a LUN from one volume to another within a cluster

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The lun copy start command initiates copying of a LUN from one volume to another. The destination volume can be located in the same Vserver as the source volume (intra-Vserver copy) or in a different Vserver (inter-Vserver).

Note: A cluster administrator must first create a Vserver peering relationship using vserver peer create before initiating an inter-Vserver LUN copy operation.

Parameters
-vserver <Vserver Name> - Destination Vserver Name
   Specifies the name of the Vserver that will host the new LUN.

|destination-path <path> - Destination Path
   Specifies the full path to the new LUN, in the format /vol/<volume>[/<qtree>]/<lun>.

-source-path <path> - Source Path
   Specifies the full path to the source LUN, in the format /vol/<volume>[/<qtree>]/<lun>.

[source-vserver <vserver name>] - Source Vserver Name
   Optionally specifies the name of the Vserver hosting the LUN to be copied.
   If this parameter is not specified, it is assumed that an intra-Vserver copy operation is being initiated. The source volume is expected to be in the same Vserver as the destination volume.

[promote-early [true]] - Promote Early
   Optionally specifies that the destination LUN needs to be promoted early.
   If the destination is promoted early, the new LUN will be visible immediately. However, Snapshot copies of the volume containing the new LUN cannot be taken until the LUN copy operation reaches 'Moving Data' status.
   If the destination is promoted late, the new LUN will be visible only after it has been fully framed. However, the LUN copy job will not block the creation of Snapshot copies of the volume containing the new LUN.
   If this parameter is not specified, the destination LUN will be promoted late.

-max-throughput (<integer> [KB | MB | GB | TB | PB]) - Maximum Transfer Rate (per sec)
   Optionally specifies the maximum amount of data, in bytes, that can be transferred per second in support of this operation. This mechanism can be used to throttle a transfer, to reduce its impact on the performance of the source and destination nodes.
   If this parameter is not specified, throttling is not applied to the data transfer.

Note: The specified value will be rounded up to the nearest megabyte.
### Examples

```
cluster1::> lun copy start -vserver vs2 -destination-path /vol/vol2/lun2 -source-vserver vs1 -source-path /vol/vol1/lun1
```

Starts an inter-Vserver copy of LUN `lun1` from volume `vol1` in Vserver `vs1` to `lun2` on volume `vol2` in Vserver `vs2`.

```
cluster1::> lun copy start -vserver vs1 -destination-path /vol/vol2/lun2 -source-path /vol/vol1/lun1
```

Starts an intra-Vserver copy of LUN `lun1` from volume `vol1` in Vserver `vs1` to `lun2` on volume `vol2` in Vserver `vs1`.

```
cluster1::> lun copy start -vserver vs1 -destination-path /vol/vol2/lun2 -source-path /vol/vol1/snapshot/snap1/lun1
```

### lun igroup commands

Manage initiator groups

#### lun igroup add

Add initiators to an initiator group

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

**Description**

This command adds initiators to an existing initiator group (igroup). You can add an initiator to an initiator group only if there are no LUN mapping conflicts. Mapping conflicts occur when an initiator is already paired with a LUN. If you attempt to run this command and there are LUN mapping conflicts, the command returns an error.

An initiator cannot be a member of two igroups of different OS types. For example, if you have an initiator that belongs to a Solaris igroup, the command does not allow you to add this initiator to an AIX igroup.

When you add FCP initiators, you can specify an alias instead of the initiator’s World Wide Port Name (WWPN) or the iSCSI Qualified name (IQN).

**Parameters**

- `-vserver <Vserver Name>` - Vserver Name
  
  Specifies the Vserver.

- `-igroup <text>` - Igroup Name
  
  Specifies the initiator group to which you want to add a new initiator.

- `-initiator <text>, ...` - Initiators
  
  Specifies the initiator that you want to add. You can specify the WWPN, IQN, or alias of the initiator.
lun igroup bind

Bind an existing initiator group to a given portset

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

**Description**
This command binds an initiator group to a port set so the host knows which LIFs or TPGs to access. When you bind a port set to an igroup, the host knows which iSCSI or FCP LIF to access. If you do not bind an igroup to a port set, and you map a LUN to the igroup, then the initiators in the igroup can access the LUN on any port on the Vserver.

The initiator group cannot be bound to another port set when you use this command. If you attempt to bind a port set to an initiator group that is already bound to an existing port set, the command returns an error. You can only bind an initiator group to one port set at a time.

If the initiator group is bound, use the `lun igroup unbind` command to unbind the initiator group from the port set. After the initiator group is unbound, you can bind it to another port set.

You can only bind an initiator group to a non-empty port set.

**Parameters**
- `--vserver <Vserver Name>` - Vserver Name
  Specifies the Vserver.
- `--igroup <text>` - Igroup Name
  Specifies the initiator group that you want to bind a port set to.
- `--portset <text>` - Portset Binding Igroup
  Specifies the port set name that you want to bind an initiator group to.

**Examples**

```
cluster1::> lun igroup bind --vserver vs1 --igroup ig1 --portset-name ps1
```

**Related references**
- `lun igroup unbind` on page 201

lun igroup create

Create a new initiator group

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

**Description**
This command creates a new initiator group (igroup). Use igroups to control which hosts have access to specific LUNs. When you bind an igroup to a port set, a host in the igroup can access the LUNs only by connecting to the target ports in the port set.

When you create an igroup, you can add multiple existing initiators by specifying them in a list, separating them with commas. Later, you can add or remove initiators from the initiator group. Use the `lun igroup add` command to add initiators. Use the `lun igroup remove` command to remove an initiator. Unless the `--initiator` option is supplied, no initiators are added to a new igroup.
You can also bind a port set to an initiator when you create an initiator group. You can modify the port set binding of an initiator group by using the `lun igroup bind` command or the `lun igroup unbind` command.

The name you assign to an igroup is independent of the name of the host that is used by the host operating system, host files, or Domain Name Service (DNS). If you name an igroup aix1, for example, it is not mapped to the actual IP host name (DNS name) of the host.

**Parameters**

`-vserver <Vserver Name>` - Vserver Name

Specifies the Vserver.

`-igroup <text>` - Igroup Name

Specifies the name of the new initiator group. An initiator group name is a case-sensitive name that must contain one to 96 characters. Spaces are not allowed.

**Note:** It might be useful to provide meaningful names for igroups, ones that describe the hosts that can access the LUNs mapped to them.

{ [...protocol <protocol_enum>] - Protocol

Specifies if the initiator group protocol is `fcp`, `iscsi`, or `mixed`.

 | [-fcp | -f {true}] - FCP

Specifies FCP as the protocol type of the new igroup.

 | [-iscsi | -i {true}] - iSCSI

Specifies iSCSI as the protocol type of the new igroup.

`-ostype | -t {solaris|windows|hpux|aix|linux|netware|vmware|openvms|xen|hyper_v} - OS Type`

Specifies the operating system type for the new initiator group. The operating system type indicates the type of host operating system used by all of the initiators in the igroup. All initiators in an igroup must be of the same operating system type. The operating system types of initiators are:

- solaris
- windows
- hpux
- aix
- linux
- netware
- vmware
- openvms
- xen
- hyper_v

`[-portset | -a <text>] - Portset Binding Igroup`

Specifies that a port set is bound to the initiator.

`-initiator <text>, ... - Initiators`

Specifies the initiators that are attached to the new initiator group. By default, no initiators are added to the new igroup.
Examples

cluster1::> lun igroup create -vserver vs1 -igroup ig1 -protocol mixed -ostype linux -initiator 
  iqn.2001-04.com.example:abc123

lun igroup delete

Delete an initiator group

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
This command deletes an existing initiator group. By default, you cannot delete an initiator group if LUN maps for that initiator group exist. You need to unmap all the LUNs that are associated with that initiator group before you can delete the initiator group. Use the lun unmap command to remove LUNS from an initiator group.

You can specify the force option to delete an initiator group and remove existing LUN maps defined for that initiator group.

Parameters
-vserver <Vserver Name> - Vserver Name
  Specifies the Vserver.
-igroup <text> - Igroup Name
  Specifies the initiator group that you want to delete.
[-force | -f [true]] - Force
  Deletes an initiator group and all associated LUN maps.

Examples

cluster1::> lun igroup delete -vserver vs1 -igroup ig1

Related references

lun mapping delete on page 212

lun igroup disable-aix-support

Disables SAN AIX support on the cluster

Availability: This command is available to cluster and Vserver administrators at the advanced privilege level.

Description
This command disables the SAN AIX support across the cluster (all Vservers and all AIX initiator groups). However, before you can disable SAN AIX support, you must remove all SAN AIX related objects from the cluster. You need to unmap all the LUNs that are associated with the AIX initiator groups. Then you need to delete all of the AIX initiator groups. Use the lun unmap command to remove LUNS from an initiator group. Use the igroup delete command to delete an initiator group.
**Note:** This command is not intended to be used in normal operation. Use only when you are downgrading to a release that does not support SAN AIX operation.

### Examples

```
cluster1:~> lun igroup disable-aix-support
```

### Related references

- [lun mapping delete](#) on page 212

### lun igroup modify

Modify an existing initiator group

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

**Description**

This command modifies an attribute for an initiator group. Currently, the only settable attribute is the operating system.

### Parameters

- `-vserver <Vserver Name>` - Vserver Name
  Specifies the Vserver.

- `-igroup <text>` - Igroup Name
  Specifies the initiator group whose attribute you want to modify.

- `-ostype {solaris|windows|hpux|aix|linux|netware|vmware|openvms|xen|hyper_v}` - OS Type
  Specifies the operating system that you want to modify. The operating system types of initiators are:
  - solaris
  - windows
  - hpux
  - aix
  - linux
  - netware
  - vmware
  - openvms
  - xen
  - hyper_v

- `-delete-on-unmap {true|false}` - Delete on Last Unmap
  Specifies if this initiator group will be deleted automatically when no longer used in a LUN mapping relationship.
Examples

    cluster1::> lun igroup modify -vserver vs1 -igroup ig1 -ostype windows

lun igroup remove

Remove initiators from an initiator group

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
This command removes an initiator from an initiator group. You can only remove an initiator if no existing LUN maps are defined for that initiator group. You must unmapped the LUNs from the initiator group with the lun unmap command before you can remove initiators from the initiator group.

You can use the force option to remove an initiator and associated LUN maps.

Parameters
-vserver <Vserver Name> - Vserver Name
    Specifies the Vserver.
-igroup <text> - Igroup Name
    Specifies the initiator group from which you want to remove an initiator.
-initiator <text>, ... - Initiators
    Specifies the initiator name you want to remove. Use the WWPN, IQN or the alias of the initiator.
[-force |-f [true]] - Force
    Forcibly removes an initiator and any associated LUN maps.

Examples

    cluster1::> lun igroup remove -vserver vs1 -igroup ig1 -initiator iqn.1992-08.com.mv.mvinitiator

Related references

    lun mapping delete on page 212

lun igroup rename

Rename an existing initiator group

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
This command renames an existing initiator group. When you rename an initiator group, this action does not affect access to the LUNs mapped to the initiator group you want to rename.

An initiator group name is a case-sensitive name and must meet the following requirements:

- Must contain one to 96 characters. Spaces are not allowed.
- Can contain the letters A through Z, a through z, numbers 0 through 9, hyphen (-), underscore (_), colon (:), and period (.).
- Must start with a letter or number.
Parameters

- **vserver <Vserver Name>** - Vserver Name
  Specifies the Vserver.

- **igroup <text>** - Igroup Name
  Specifies the initiator group you want to rename.

- **new-name <text>** - New Igroup Name
  Specifies the new name of the initiator group.

---

### Examples

```
cluster1::> lun igroup rename -vserver vs1 -igroup ig1 -new-name ignew1
```

---

### lun igroup show

Display a list of initiator groups

**Availability:** This command is available to cluster and Vserver administrators at the admin privilege level.

**Description**
This command displays status information for initiator groups (igroup). By default, the command displays status for all initiator groups.

**Parameters**

{ [-fields <fieldname>, ...]  
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

| [-instance ]  
If you specify the -instance parameter, the command displays detailed information about all fields.

[-vserver <Vserver Name>] - Vserver Name
  Specifies the Vserver.

[-igroup <text>] - Igroup Name
  Selects the initiator groups that match this parameter value.

[-protocol <protocol_enum>] - Protocol
  Selects the initiator groups that match this parameter value (FCP, iSCSI, or mixed).

[-ostype | -t {solaris|windows|hpux|aix|linux|netware|vmware|openvms|xen|hyper_v}] - OS Type
  Selects the initiator groups that match this parameter value. The operating system types are
  
  • solaris
  • windows
  • hpux
  • aix
  • linux
  • netware
  • vmware

---

200

Commands: Manual Page Reference
• openvms
• xen
• hyper_v

`[-portset] -a <text>` - Portset Binding Igroup
Selects the initiator groups that match this parameter value.

`[-initiator <text>, ...] - Initiators`
Selects the initiator groups that match this parameter value.

`[-uuid <UUID>] - Igroup UUID`
Selects the initiator groups that match this parameter value.

`[-delete-on-unmap {true|false}] - Delete on Last Unmap`
Selects the initiator groups that match this parameter value. A value of true displays all the initiator groups that will be deleted automatically when they are no longer used in a LUN mapping relationship.

**Examples**

```bash
cluster1::> igroup show -instance
  Vserver Name: vs0
  Igroup Name: ig1
  Protocol: mixed
  OS Type: linux
  Portset Binding Igroup: -
  Igroup UUID: 358338ba-cfd6-11df-a9ab-123478563412
  Initiators:iqn.1992-08.com.mv:abc (not logged in)

  Vserver Name: vs0
  Igroup Name: ig2
  Protocol: mixed
  OS Type: linux
  Portset Binding Igroup: -
  Igroup UUID: 3fb136c7-cfd6-11df-a9ab-123478563412
  Initiators: -

  Vserver Name: vs1
  Igroup Name: ig1
  Protocol: mixed
  OS Type: windows
  Portset Binding Igroup: pl
  Igroup UUID: 03accf6b-d08c-11df-a9ab-123478563412
  Initiators: -
3 entries were displayed.
```

**lun igroup unbind**

Unbind an existing initiator group from a portset

**Availability:** This command is available to cluster and Vserver administrators at the admin privilege level.

**Description**
This command unbinds an initiator group from a port set. When you unbind an initiator group from a port set, all of the initiators in the initiator group have access to all target LUNs on all network interfaces.

**Parameters**

`-vserver <Vserver Name>` - Vserver Name
Specifies the Vserver.
**-igroup <text> - Igroup Name**

Specifies the initiator group that you want to unbind from the port set.

<table>
<thead>
<tr>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>cluster1::&gt; lun igroup unbind -vserver vs1 -igroup ig1</td>
</tr>
</tbody>
</table>

---

**lun import commands**

Manage Foreign LUN Import

**lun import create**

Create an import relationship

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

**Description**

This command creates an import relationship between a specified LUN and a specified foreign disk so you can import the foreign disk data into a LUN.

The foreign disk must be marked as foreign using `storage disk set-foreign-lun` command before you can begin the import progress.

The LUN must be of the same size as the foreign disk.

**Parameters**

- `-vserver <Vserver Name> - Vserver Name`
  
  Specifies the Vserver that contains the LUN where you import data to from the foreign disk data.

- `-foreign-disk <text> - Foreign Disk Serial Number`
  
  Specifies the serial number of the Foreign Disk.

- `-path <path> - LUN Path`
  
  Specifies the path of the LUN where you want to import the data of the foreign disk to. Examples of correct LUN paths are `/vol/vol1/lun1` and `/vol/vol1/qtree1/lun1`.

<table>
<thead>
<tr>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>cluster1::&gt; lun import create -vserver vs1 -path /vol/dvol1/lun1 -foreign-disk 6000B5D0006A0000006A020E00000</td>
</tr>
</tbody>
</table>

**Related references**

`storage disk set-foreign-lun` on page 948

**lun import delete**

Deletes the import relationship of the specified LUN or the specified foreign disk

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

**Description**

This command deletes the import relationship of a specified LUN or a specified foreign disk.
You cannot use this command if an import is in-progress between the foreign disk and the LUN unless you use the force option. The import has to either successfully completed or be stopped before deleting the import relationship.

You can use the `lun import stop` command to stop the data import, and then you delete the import relationship.

**Parameters**

- `vserver <Vserver Name>` - Vserver Name
  
  Specifies the Vserver that contains the LUN that you want to delete the import relationship.

- `path <path>` - LUN Path
  
  Specifies the path of the LUN where you want to delete the import relationship. Examples of correct LUN paths are `/vol/vol1/lun1` and `/vol/vol1/qtree1/lun1`.

- `foreign-disk <text>` - Foreign Disk Serial Number
  
  Specifies the serial number of the foreign disk.

- `[force {true|false}]` - Force Delete
  
  When set to true, stops the in progress data import.

**Examples**

```
cluster1::> lun import delete -vserver vs1 -path /vol/vol2/lun2
```

 Deletes the import relationship of lun2 at the path `/vol/vol2/lun2`. 

```
cluster1::> lun import delete -vserver vs0 -foreign-disk 6000B5D00006A0000006A020E00040000
```

**Related references**

`lun import stop` on page 208

#### lun import pause

Pause the import for the specified LUN

**Availability:** This command is available to `cluster` administrators at the `advanced` privilege level.

**Description**

This command pauses the data import to a specified LUN.

This command does not reset all import checkpoints. To resume a paused import, use the `lun import resume` command to restart from the last checkpoint taken before you paused the data import.

If you want to resume the data import from the beginning, use the `lun import stop` command. Then use the `lun import start` command.

**Parameters**

- `vserver <Vserver Name>` - Vserver Name
  
  Specifies the Vserver that contains the LUN you want to pause the data import to.

- `path <path>` - LUN Path
  
  Specifies the path of the LUN you want to pause the data import to. Examples of correct LUN paths are `/vol/vol1/lun1` and `/vol/vol1/qtree1/lun1`. 

`lun import commands`
lun import prepare-to-downgrade

Prepares LUN import to be downgraded

**Availability:** This command is available to cluster administrators at the advanced privilege level.

**Description**
This command prepares the cluster for a downgrade to a version of Data ONTAP earlier than 8.3.1 by disabling the online LUN import feature. Before using this command verify that all LUNs in an import relationships are offline by running `lun show`.

**Examples**

```
cluster1::> lun import prepare-to-downgrade
```

**Related references**

`lun show` on page 181

lun import resume

Resume the import for the specified LUN

**Availability:** This command is available to cluster administrators at the advanced privilege level.

**Description**
Resumes the data import to a specified LUN.

The import starts from the last checkpoint taken before you paused the data import.

If you want to resume the data import from the beginning, use the lun import stop command. Then use the lun import start command.

**Parameters**

- `-vserver <Vserver Name>` - Vserver Name
  Specifies the Vserver that contains the LUN you want to resume the data import to.

- `-path <path>` - LUN Path
  Specifies the path of the LUN that you want to resume the data import to. Examples of correct LUN paths are `/vol/vol1/lun1` and `/vol/vol1/qtree1/lun1`.

**Examples**

```
cluster1::> lun import resume -vserver vs1 -path /vol/vol2/lun2
```

lun import show

Display a list of import relationships

**Availability:** This command is available to cluster administrators at the advanced privilege level.
Description
This command displays information about the import relationships.

Parameters

{ [-fields <fieldname>, ...]  
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use `-fields ?' to display the fields to specify.  

[-instance]  
If you specify the -instance parameter, the command displays detailed information about all fields.  

[-vserver <Vserver Name>] - Vserver Name  
Displays import relationships for a specified Vserver.  

[-foreign-disk <text>] - Foreign Disk Serial Number  
Enables you to see the import relationship for a particular foreign disk with the specified serial number.  

[-path <path>] - LUN Path  
Enables you to see the import relationship for a particular LUN path. Examples of correct LUN paths are /vol/vol1/lun1 and /vol/vol1/qtree1/lun1.  

[-import-home-node <nodename>|local] - Import Home Node  
Enables you to see the node that initially started the data import and where the I/O for the foreign disk is directed. If failover occurs, any in-progress data import restarts on the partner node.  

[-import-current-node <nodename>|local] - Import Current Node  
Displays the node that is currently importing data and where the I/O for the foreign disk is directed. During giveback and if the import home node is different from the current home node, import restarts on the initial node (import-home-node).  

[-operation-in-progress {import|verify}] - Operation in Progress  
Enables you to see the imports in progress or import verification in progress.  

[-admin-state {stopped|started|paused}] - Admin State  
Enables you to see the import relationships for a specified administrative state. For example, you can list all the imports that have started in a cluster.  

[-operational-state {in_progress|failed|completed|stopped|paused}] - Operational State  
Enables you to see the import relationships for a specified operational state. For example, you can list all the imports that have completed in a cluster.  

[-percent-complete <integer>] - Percent Complete  
Enables you to see the percentage of completion for both import and verification. If you want to see all the complete imports and verifications, you would specify 100.  

[-imported-blocks <integer>] - Blocks Imported  
Enables you to see the number of blocks that have been imported to the LUN.  

[-compared-blocks <integer>] - Blocks Compared  
Enables you to see the number of LUN and foreign disk blocks that have been compared.  

[-total-blocks <integer>] - Total Blocks  
Enables you to see the total number of blocks that must be imported to complete the data import to a LUN or the number of blocks that must be compared to complete the import verification.  

[-estimated-remaining-duration {<seconds> | [<d> days] <hh>:<mm>[:<ss>]]}] - Estimated Remaining Duration  
If this parameter is specified, the command displays import or verify operations that match the specified time.
([-failure-reason <text>]) - Failure Reason

Selects LUN import operations that match this parameter value.

([-max-throughput-limit {<integer>[KB|MB|GB|TB|PB]}]) - Maximum Throughput Limit (per sec)

Selects the LUN import operations that match this parameter value. This value is the throughput limit at which an import or verify will be throttled. By default, there is no throttling.

([-current-throughput {<integer>[KB|MB|GB|TB|PB]}]) - Current Throughput (per sec)

Selects the LUN import operations that match this parameter value. This value is the current throughput for an in-progress import or verify operation.

([-qos-policy-group <text>]) - QoS Policy Group

Selects the LUN import operations that match this parameter value. This value is the QoS policy group associated with an import relationship.

### Examples

```
cluster1::> lun import show

vserver           foreign-disk                      path                    operation-in-
progress   admin-state  operational-state  percent-complete

```

**lun import start**

Start the import for the specified LUN

**Availability:** This command is available to cluster administrators at the advanced privilege level.

**Description**

This command initiates the data import to a specified LUN.

You must use the lun import create command to create an import relationship between a LUN and a foreign disk before you can initiate the data import.

**Parameters**

- **-vserver <Vserver Name>** - Vserver Name
  
  Specifies the Vserver that contains the LUN you want to import data to.

- **-path <path>** - LUN Path
  
  Specifies the path of the LUN that you want to import data to. Examples of correct LUN paths are /vol/vol1/lun1 and /vol/vol1/qtree1/lun1.

**Examples**

```
cluster1::> lun import start -vserver vs1 -path /vol/vol2/lun2
```

**lun import commands** 207
**lun import stop**

Stop the import for the specified LUN

**Availability:** This command is available to cluster administrators at the advanced privilege level.

**Description**
This command stops the data import into a specified LUN.

After you stop the data import and if you start the import again using `lun import start` command, then the import restarts from the beginning.

**Parameters**

- `-vserver <Vserver Name>` - **Vserver Name**
  
  Specifies the Vserver that contains the LUN you want to stop importing data to.

- `-path <path>` - **LUN Path**
  
  Specifies the path of the LUN that you want to stop the data import to.

**Examples**

```
cluster1::> lun import stop -vserver vs1 -path /vol/vol2/lun2
```

**Related references**

- `lun import start` on page 207

---

**lun import throttle**

Modify the max throughput limit for the specified import relationship

**Availability:** This command is available to cluster administrators at the advanced privilege level.

**Description**
This command throttles the speed of the import for a given LUN by specifying a maximum throughput limit on the import.

**Parameters**

- `-vserver <Vserver Name>` - **Vserver Name**
  
  Specifies the Vserver that contains the LUN to which data from the foreign disk is imported.

- `-path <path>` - **LUN Path**
  
  Specifies the path of the LUN to which data from the foreign disk is imported. Examples of correct LUN paths are `/vol/vol1/lun1` and `/vol/vol1/qtree1/lun1`.

- `-max-throughput-limit <integer>[KB|MB|GB|TB|PB]` - **Maximum Throughput Limit (per sec)**
  
  Specifies the maximum amount of throughput to be allocated for processing import requests on the bound LUN. At the time of creation, the default is zero. A value of zero implies that import traffic is processed by the system at best effort rate along with on-going user I/O. A non-zero value indicates that import will be throttled at a rate which is at most the maximum throughput limit set.

**Examples**

```
cluster1::*> lun import throttle -vserver vs1 -path /vol/vol1/lun1 -max-throughput-limit 3M
```
lun import verify commands

Manage Foreign LUN import verify

lun import verify start

Start the verification of the foreign disk and LUN data

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

**Description**
This command compares the LUN and the foreign disk block by block. You are not required to run this command; it is optional. Before you can do this verification process, the operation state must be stopped or completed. Use the lun import show command to determine the operation state.

If a block mismatch occurs, the verification process stops.

Verification must be done offline. Ensure the foreign disk and LUN cannot be accessed by a host. To prevent access of the LUN, the LUN should be taken offline administratively using the lun offline command.

Note: The specified LUN must be in an import relationship with a foreign disk before you can verify the data import.

**Parameters**

- **-vserver <Vserver Name>** - Vserver Name
  Specifies the Vserver that contains the LUN you want to compare block by block with the foreign disk.

- **-path <path>** - LUN Path
  Specifies the path of the LUN that you want to compare the foreign disk to. Examples of correct LUN paths are /vol/vol1/lun1 and /vol/vol1/qtree1/lun1.

**Examples**

```
cluster1::> lun import verify start -vserver vs1 -path /vol/vol2/lun2
```

lun import verify stop

Stop the verify for the specified LUN

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

**Description**
This command stops the block by block verification of the foreign disk and LUN data.

**Parameters**

- **-vserver <Vserver Name>** - Vserver Name
  Specifies the Vserver that contains the LUN you want to stop block by block comparison with the foreign disk.

- **-path <path>** - LUN Path
  Specifies the path of the LUN that you want to stop the block by block comparison. Examples of correct LUN paths are /vol/vol1/lun1 and /vol/vol1/qtree1/lun1.
Examples

cluster1:~> lun import verify stop -vserver vs1 -path /vol/vol2/lun2

lun mapping commands

Manage LUN Maps

lun mapping add-reporting-nodes

Add Reporting Nodes

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description

This command is used before or after a data mobility event that modifies the owning node of the LUN to add the new optimized nodes to the specified LUN mapping's reporting nodes.

For more information on managing reporting nodes in response to data mobility events, please see the Data ONTAP SAN Administration Guide.

Parameters

-vserver <Vserver Name> - Vserver Name

Specifies the name of the Vserver containing the LUN.

{-path <path> - LUN Path

Specifies the path of the LUN. Examples of correct LUN paths are /vol/vol1/lun1 and /vol/vol1/qtree1/lun1.

| -volume <volume name> - Volume Name

Specifies the volume that contains the LUN.

[-qtree <qtree name>] - Qtree Name

Specifies the qtree that contains the LUN.

-lun <text> - LUN Name

Specifies the LUN name.

-igroup | -g <text> - Igroup Name

Specifies the igroup the LUN is mapped to.

{-local-nodes [true] - Add Nodes for Current LUN Location

Add the current LUN owner node and HA partner to the LUN mapping's reporting nodes.

This option should be used after a LUN mobility event to restore optimized access to the LUN.

| -destination-aggregate <aggregate name> - Add Nodes for Aggregate

Add the specified aggregate's owner node and HA partner to the LUN mapping's reporting nodes.

This option may be used prior to a LUN mobility event that changes the LUN's containing aggregate.
Add Nodes for Volume

Add the specified volume's owner node and HA partner to the LUN mapping's reporting nodes.
This option may be used prior to a LUN mobility event that changes the LUN's containing volume.

Add All Nodes (privilege: advanced)

Set the LUN mapping to report on all nodes in preparation for a revert to a previous version of Data ONTAP.

Examples

```
cluster1::> lun mapping add-reporting-nodes -vserver vs1 -path /vol/vol1/lun1 -igroup ig1
```

Add the current owner node and HA partner for the LUN mapping of /vol/vol1/lun1 to igroup ig1

```
cluster1::> lun mapping add-reporting-nodes -vserver vs1 -volume vol1 -lun * -igroup ig1
```

lun mapping create

Map a LUN to an initiator group

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
This command maps a LUN to all of the initiators in an initiator group (igroup). After you map the LUN, the LUN is visible to all initiators in the igroup.

Data ONTAP ensures that there are no LUN map conflicts whether the LUN is offline or online. A LUN map conflict is a mapping that would violate either of the following rules:

- Each LUN can be mapped to an initiator only once. A LUN can be mapped to multiple igroups as long as each igroup has a distinct set of initiators.
- LUN IDs must be unique such that every initiator has a unique ID for each LUN to which it is mapped. If you map a LUN to an igroup, the LUN ID for that mapping cannot be reused by any of the initiators in that igroup.

In order to determine if a LUN ID is valid for a mapping, Data ONTAP checks each initiator in the igroup to make sure that the LUN ID is not used for another mapping that includes that initiator.

Note: Prior to mapping a LUN, you must have at least one iSCSI or FCP LIF provisioned on the LUN's owner node and high-availability partner node.

Parameters

- `vserver <Vserver Name>` - Vserver Name
  Specifies the Vserver that contains the LUN you want to map.

  `{ -path <path> } - LUN Path
  Specifies the path of the LUN that you want to map. Examples of correct LUN paths are /vol/vol1/ and /vol/vol1/qtree1/lun1.

- `volume <volume name>` - Volume Name
  Specifies the volume that contains the LUN you want to map.

  [ -qtree <qtree name> ] - Qtree Name
  Specifies the qtree that contains the LUN you want to map.
-lun <text> - LUN Name
   Specifies the LUN name that you want to map.
-igroup | -g <text> - Igroup Name
   Specifies the igroup that you want to map.

-[lun-id <integer>] - LUN ID
   Specifies the LUN ID for the mapping. The LUN ID is specific to the mapping, not to the LUN itself. This is used by the initiators in the igroup as the Logical Unit Number for the initiator when accessing the storage.

-[additional-reporting-node <nodename>] - Additional Reporting Node (privilege: advanced)
   Specifies an additional node to populate the -reporting-nodes list when creating the LUN mapping. The specified node's high availability partner will be automatically populated as well. Use this parameter when preferred data mobility destinations are known ahead of time and the appropriate paths can be pre-configured.

Examples

cluster1::> lun mapping create -vserver vs1 -path /vol/vol1/lun1 -igroup ig1 -lun-id 8

lun mapping delete

Unmap a LUN from an initiator group

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
This command unmaps a LUN from an initiator group. After you use this command, the LUN is not visible to any of the initiators in the initiator group.

Parameters
-vserver <Vserver Name> - Vserver Name
   Selects the LUN maps for the Vserver that matches the parameter value.

{ -path <path> - LUN Path
   Specifies the path of the LUN you want to unmap. Examples of correct LUN paths are /vol/vol1/lun1 and /vol/vol1/qtree1/lun1.

   -volume <volume name> - Volume Name
   Specifies the volume of the LUN you want to unmap.

   -qtree <qtree name> - Qtree Name
   Specifies the qtree of the LUN you want to unmap.

   -lun <text> - LUN Name
   Specifies the name of the LUN you want to unmap.

   -igroup | -g <text> - Igroup Name
   Specifies the initiator group that you want to unmap the LUN from.

Examples

cluster1::> lun mapping delete -vserver vs1 -path /vol/vol1/lun1 -igroup ig1
**lun mapping remove-reporting-nodes**

Remove Reporting Nodes

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

**Description**
This command is used after a data mobility event to remove reporting nodes that are no longer required for optimized access from the specified LUN mapping.

For more information on managing reporting nodes in response to data mobility events, please see the Data ONTAP SAN Administration Guide.

**Parameters**

- **vserver** `<Vserver Name>` - *Vserver Name*
  Specifies the name of the Vserver containing the LUN.

- **-path** `<path>` - *LUN Path*
  Specifies the path of the LUN. Examples of correct LUN paths are `/vol/vol1/lun1` and `/vol/vol1/qtree1/lun1`.

- **-volume** `<volume name>` - *Volume Name*
  Specifies the volume that contains the LUN.

- **-qtree** `<qtree name>` - *Qtree Name*
  Specifies the qtree that contains the LUN.

- **-lun** `<text>` - *LUN Name*
  Specifies the LUN name.

- **-igroup** `-g` `<text>` - *Igroup Name*
  Specifies the igroup the LUN is mapped to.

- **-remote-nodes** `[true]` - Remove Remote Nodes for LUN Location
  If specified, remove all nodes other than the LUN's owner and HA partner from the LUN mapping's reporting nodes.

**Examples**

```
cluster1::> lun mapping remove-reporting-nodes -vserver vs1 -path /vol/vol1/lun1 -igroup ig1
```

**lun mapping show**

Lists the mappings between LUNs and initiator groups.

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

**Description**
This command lists the mappings between LUNs and initiator groups.

**Parameters**

{ [**-fields** `<fieldname>`, ...] 
If you specify the `-fields` `<fieldname>`, ... parameter, the command output also includes the specified field or fields. You can use `'-fields ?'` to display the fields to specify.
If you specify the \texttt{\-instance} parameter, the command displays detailed information about all fields.

\begin{verbatim}
[-vserver <Vserver Name>] - Vserver Name
Selects the LUN maps for the Vserver that matches the parameter value.

([-path <path>]) - LUN Path
Selects the LUN maps for the LUN with the path that matches the parameter value. Examples of correct LUN paths are /vol/vol1/lun1 and /vol/vol1/qtree1/lun1.

([-volume <volume name>]) - Volume Name
Selects the LUN maps for the volumes that match the parameter value.

([-qtree <qtree name>]) - Qtree Name
Selects the LUN maps for the queue trees that match the parameter value.

([-lun <text>]) - LUN Name
Selects the LUN maps for the LUNs with a name that matches the parameter value.

([-igroup | -g <text>]) - Igroup Name
Selects the LUN maps for the igroup that matches the parameter value.

([-ostype {solaris|windows|hpux|aix|linux|netware|vmware|openvms|xen|hyper_v}]) - Igroup OS Type
Selects the LUN maps for the initiator groups with the OS type that matches the parameter value. The possible OS types are:

- \texttt{solaris} - the LUN stores Solaris raw disk in a single-slice partition.
- \texttt{windows} - the LUN stores a raw disk type in a single-partition Windows disk using the Master Boot Record (MBR) partitioning style.
- \texttt{hpux} - the LUN stores HP-UX data.
- \texttt{linux} - the LUN stores a Linux raw disk without a partition table.
- \texttt{netware} - the LUN stores NetWare data.
- \texttt{vmware} - the LUN stores VMware data.
- \texttt{openvms} - the LUN stores Open-VMS data.
- \texttt{xen} - the LUN stores Xen data.
- \texttt{hyper_v} - the LUN stores Windows Server 2008 or Windows Server 2012 Hyper-V data.

([-protocol <protocol_enum>]) - Igroup Protocol Type
Selects the LUN maps for initiator groups with a protocol that matches the parameter value. Possible values include FCP, iSCSI, or mixed.

([-lun-id <integer>]) - LUN ID
Selects the LUN maps with a LUN ID that matches the parameter value.

([-portset <text>]) - Portset Binding Igroup
Selects the LUN maps for initiator groups bound to the portset that matches the parameter value.

([-alua {true|false}]) - ALUA
Selects the LUN maps with ALUA settings that match the parameter value.

([-initiators | -n <text>, ...]) - Initiators
Selects the LUN maps for initiator groups containing the initiators that match the parameter value.
\end{verbatim}
-node <nodename> - LUN Node
  Selects the LUN maps for nodes that match the parameter value.

-Reporting-nodes <nodename>, ... - Reporting Nodes
  Selects the LUN maps that match the parameter value.

lun mapping show-initiator

Show the LUN mappings to a specific initiator

Availability: This command is available to cluster and Vserver administrators at the advanced privilege level.

Description
The lun mapping show-initiator command lists the LUNs which are mapped to an initiator group which contains a specific initiator.

Parameters

[-fields <fieldname>, ...]
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

[-instance ]
If you specify the -instance parameter, the command displays detailed information about all fields.

[-vserver <Vserver Name>] - Vserver Name
Selects the LUN mappings for the vserver that you specify.

-initiator <text> - Initiator Name
Selects the LUN mappings for the initiator that you specify.

[-lun-id <integer>] - Logical Unit Number
Selects the LUN mappings with a LUN ID that you specify.

[-igroup <text>] - Igroup Name
Selects the LUN mappings for the initiator group that you specify.

[-path <path>] - LUN Path
Selects the LUN mappings for the LUN path that you specify.

[-node <nodename>] - LUN Node
Selects the LUN mappings for the LUNs which are being hosted on the node that you specify.

-Reporting-nodes <nodename>, ... - Reporting Nodes
Selects the LUN mappings for the LUNs which have reporting nodes that you specify.

[-vserver-uuid <UUID>] - Vserver UUID
Selects the LUN mappings for the Vserver UUID that you specify.
[–igroup-uuid <UUID>] - Igroup UUID

Selects the LUN mappings for the initiator group UUID that you specify.

[–lun-uuid <UUID>] - LUN UUID

Selects the LUN mappings for the LUN UUID that you specify.

Examples

The following example displays the LUN mappings for initiator 20:10:0a:50:00:01:01:01 in Vserver vs1.

```bash
cluster1:/> lun mapping show-initiator -vserver vs1 -initiator 20:10:0a:50:00:01:01:01

Vserver  Initiator  LUN ID  Path                                IGroup
-------  --------- ------ ----------------------------------- ----------------
 vs1      20:10:0a:50:00:01:01:01
 0 /vol/igroup_1_1_vol/lun1            igroup_1
 2 /vol/igroup_1_1_vol/lun3            igroup_1
 3 /vol/igroup_1_2_vol/lun1            igroup_1
 5 /vol/igroup_1_2_vol/lun3            igroup_1
 6 /vol/igroup_1_3_vol/lun1            igroup_1
 8 /vol/igroup_1_3_vol/lun3            igroup_1
 9 /vol/igroup_1_4_vol/lun1            igroup_1
11 /vol/igroup_1_4_vol/lun3            igroup_1
12 /vol/igroup_2_1_vol/lun1            igroup_2
14 /vol/igroup_2_1_vol/lun3            igroup_2
15 /vol/igroup_2_2_vol/lun1            igroup_2
17 /vol/igroup_2_2_vol/lun3            igroup_2
18 /vol/igroup_2_3_vol/lun1            igroup_2
20 /vol/igroup_2_3_vol/lun3            igroup_2
21 /vol/igroup_2_4_vol/lun1            igroup_2
23 /vol/igroup_2_4_vol/lun3            igroup_2
```

 Manage Lun Move Operations

Manage LUN move operations

lun move cancel

Cancel a LUN move operation before the new LUN has been created

Availability: This command is available to cluster and Vserver administrators at the advanced privilege level.

Description

The `lun move cancel` command cancels an ongoing LUN move operation prior to creation of the new LUN. The command fails if the LUN already exists at the destination path; in that case, allow the current move operation to complete and then move it back using the `lun move start` command.

All data transfers will be halted. If the source LUN was quiesced, it will be restored to normal operation.

Note: This is an advanced command because the preferred way to cancel a LUN move operation is to wait until the new LUN becomes visible, and then move it back.

Parameters

{ -vserver <Vserver Name> - Vserver Name

Specifies the name of the Vserver that will host the destination LUN.

-destination-path <path> - Destination Path

Specifies the full path to the new LUN, in the format /vol/<volume>[/<qtree>]/<lun>.}
Manage Lun Move Operations

Examples

```
cluster1:~*> lun move cancel -vserver vs1 -destination-path /vol/vol2/lun2
```

Related references

`lun move start` on page 220

### lun move modify

Modify an ongoing LUN move operation

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

**Description**
The `lun move modify` command modifies the maximum throughput of an ongoing move operation.

**Parameters**

- **`-vserver <Vserver Name>` - Vserver Name
  Specifies the name of the Vserver that will host the destination LUN.

- **`-destination-path <path>` - Destination Path
  Specifies the full path to the new LUN, in the format `/vol/<volume>[/<qtree>]/<lun>`.

- **`-max-throughput {<integer>[KB|MB|GB|TB|PB]}` - Maximum Transfer Rate (per sec)
  Specifies the maximum amount of data, in bytes, that can be transferred per second in support of this operation. This mechanism can be used to throttle a transfer, to reduce its impact on the performance of the source and destination nodes.

  **Note:** The specified value will be rounded up to the nearest megabyte.

```
Examples

```
cluster1:~*> lun move modify -vserver vs1 -destination-path /vol/vol2/lun2 -max-throughput 25MB
```

### lun move pause

Pause an ongoing LUN move operation

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

**Description**
The `lun move pause` command pauses an ongoing move operation. Use the `lun move resume` command to resume the move operation.

**Parameters**

- **`-vserver <Vserver Name>` - Vserver Name
  Specifies the name of the Vserver that will host the destination LUN.

- **`-destination-path <path>` - Destination Path
  Specifies the full path to the new LUN, in the format `/vol/<volume>[/<qtree>]/<lun>`.

```
Examples

```
cluster1:~*> lun move pause -vserver vs1 -destination-path /vol/vol2/lun2
```

Manage Lun Move Operations

217
lun move resume

Resume a paused LUN move operation

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The lun move resume command resumes a paused move operation.

Parameters
{-vserver <Vserver Name> - Vserver Name
  Specifies the name of the Vserver that will host the destination LUN.

-destination-path <path> - Destination Path
  Specifies the full path to the new LUN, in the format /vol/<volume>/[/<qtree>/]<lun>.

Examples
cluster1::> lun move resume -vserver vs1 -destination-path /vol/vol2/lun2

Related references
lun move pause on page 217

lun move show

Display a list LUNs currently being moved

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The lun move show command shows information about LUNs currently being moved in the cluster.

Parameters
{-fields <fieldname>,...]
  If you specify the -fields <fieldname>,... parameter, the command output also includes the specified field or fields. You can use ‘-fields ?’ to display the fields to specify.

[-instance]
  If you specify the -instance parameter, the command displays detailed information about all fields.

[-vserver <Vserver Name> - Vserver Name
  Selects LUN move operations that match this parameter value.

[-destination-path <text> - Destination Path
  Selects LUN move operations that match this parameter value.
[-source-path <path>] - Source Path
Selects LUN move operations that match this parameter value.

[-is-promoted-late {true|false}] - Is Destination Promoted Late
Selects LUN move operations that match this parameter value.

[-max-throughput {<integer>[KB|MB|GB|TB|PB]}] - Maximum Transfer Rate (per sec)
Selects LUN move operations that match this parameter value.

[-job-status {Preparing|Allocation-Map|Data|Destroying|Paused-Admin|Paused-Error|Complete|Destroyed}] - LUN Move Status
Selects LUN move operations that match this parameter value. The possible values are:

• Preparing - the LUN move job is in Preparing status.
• Allocation-Map - the LUN move job is in Allocating status.
• Data - the LUN move job is in Moving Data status.
• Destroying - the LUN move job is in Destroying status.
• Paused-Admin - the LUN move job is in Paused By Admin status.
• Paused-Error - the LUN move job is in Paused By Error status.
• Complete - the LUN move job is in Complete status.
• Destroyed - the LUN move job is in Destroyed status.

[-progress-percent <percent>] - LUN Move Progress (%)
Selects LUN move operations that match this parameter value.

[-elapsed-time <time_interval>] - Elapsed Time
Selects LUN move operations that match this parameter value.

[-cutover-time <time_interval>] - Cutover Time
Selects LUN move operations that match this parameter value.

[-is-snapshot-fenced {true|false}] - Is Snapshot Fenced
Selects LUN move operations that match this parameter value.

[-is-destination-ready {true|false}] - Is Destination Ready
Selects LUN move operations that match this parameter value.

[-last-failure-reason <text>] - Last Failure Reason
Selects LUN move operations that match this parameter value.

Examples

```
cluster1::> lun move show
Vserver Destination Path Status Progress
-------- ------------------------------- --------------- --------
vs1     /vol/vol2/lun1               Data            35%
vs1     /vol/vol2/lun2               Complete        100%
2 entries were displayed.
```

The example above displays information about all the LUN move operations in the cluster.

```
cluster1::> lun move show -vserver vs1 -destination-path /vol/vol2/lun1 -instance
                      Destination Vserver Name: vs1
                      Destination Path: /vol/vol2/lun1
```
lun move start

Start moving a LUN from one volume to another within a Vserver

**Availability:** This command is available to cluster and Vserver administrators at the admin privilege level.

**Description**
The `lun move start` command initiates moving of a LUN from one volume to another. The destination volume can be located on the same node as the original volume or on a different node.

**Note:** Use `lun move-in-volume` command if you want to rename the LUN or move it within the same volume.

**Note:** This command does not support movement of LUNs that are created from files.

**Parameters**

- `vserver <Vserver Name>` - Vserver Name
  Specifies the name of the Vserver that will host the new LUN.

- `destination-path <path>` - Destination Path
  Specifies the full path to the new LUN, in the format `/vol/<volume>[/<qtree>]/<lun>`.

- `source-path <path>` - Source Path
  Specifies the full path to the source LUN, in the format `/vol/<volume>[/<qtree>]/<lun>`.

- `promote-late [true]` - Promote Late
  Optionally specifies that the destination LUN needs to be promoted late.
  If the destination is promoted early, the new LUN will be visible immediately. However, Snapshot copies of the volume containing the new LUN cannot be taken until the LUN move operation reaches 'Moving Data' status.
  If the destination is promoted late, the new LUN will be visible only after it has been fully framed. However, the LUN move job will not block the creation of Snapshot copies of the volume containing the new LUN.
  If this parameter is not specified, the destination LUN will be promoted early.

- `max-throughput (<integer> [KB|MB|GB|TB|PB])` - Maximum Transfer Rate (per sec)
  Optionally specifies the maximum amount of data, in bytes, that can be transferred per second in support of this operation. This mechanism can be used to throttle a transfer, to reduce its impact on the performance of the source and destination nodes.
  If this parameter is not specified, throttling is not applied to the data transfer.

  **Note:** The specified value will be rounded up to the nearest megabyte.
Examples

cluster1::> lun move start -vserver vs1 -destination-path /vol/vol2/lun2 -source-path /vol/vol1/lun1

lun persistent-reservation commands

Manage SCSI-2 and SCSI-3 persistent reservations

Commands used for managing persistent reservations on LUNs.

lun persistent-reservation clear

Clear the SCSI-3 persistent reservation information for a given LUN

Availability: This command is available to cluster and Vserver administrators at the advanced privilege level.

Description

Clears the persistent reservation for the specified LUN.

Parameters

-vserver <Vserver Name> - Vserver Name
  Specifies the Vserver.

{ -path <path> - LUN Path
  Specifies the path of the LUN. Examples of correct LUN paths are /vol/vol1/lun1 and /vol/vol1/qtree1/lun1.
}

-volume <volume name> - Volume Name
  Specifies the volume.

-lun <text> - LUN Name
  Specifies the name of the LUN.

[{-qtree <qtree name>}] - Qtree Name
  Specifies the qtree.

Examples

cluster1::*> lun persistent-reservation clear -vserver vs_1 -path /vol/vol_1/lun_1
**lun persistent-reservation show**

Display the current reservation information for a given LUN

**Availability:** This command is available to cluster and Vserver administrators at the *advanced* privilege level.

**Description**
Displays reservation information for a specified LUN in a Vserver. Unlike other show commands, the user must specify the LUN.

**Parameters**

{ [-fields <fieldname>, ...]  
  If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

| [-instance ]  
  If you specify the `-instance` parameter, the command displays detailed information about all fields.

- `vserver <Vserver Name>` - Vserver Name  
  Specifies the Vserver.

{ [-path <path>] - LUN Path  
  Specifies the path of the LUN. Examples of correct LUN paths are `/vol/vol1/lun1` and `/vol/vol1/qtree1/lun1`.

| [-volume <volume name>] - Volume Name  
  Specifies the volume.

- `lun <text>` - LUN Name  
  Specifies the name of the LUN.

[[-qtree <qtree name>]] - Qtree Name  
  Specifies the qtree.

[-scsi-revision {scsi2|scsi3}] - SCSI Revision  
  Selects the reservations that match this parameter value.

[-entry-type {reservation|registration}] - Reservation or Registration  
  Selects the reservations that match this parameter value.

[-protocol {fcp|iscsi}] - Protocol  
  Selects the reservations that match this parameter value.

[-reservation-key <text>] - Reservation Key  
  Selects the reservations that match this parameter value.

[-reservation-type-code <text>] - Reservation Type  
  Selects the reservations that match this parameter value. The possible values for SCSI-3 reservations are:
  - write exclusive
  - exclusive access
  - write exclusive registrants only
  - exclusive access registrants only
  - write exclusive all registrants
  - exclusive access all registrants
and for SCSI-2 are:

- regular
- third party

**[-initiator-name <text>] - Initiator Name**
Selects the reservations that match this parameter value.

**[-aptpl {true|false}] - Persist Through Power Loss**
Selects the reservations that match this parameter value. If true, the reservation will be preserved over a power loss. If false, it will not. This value is for SCSI-3 reservations only.

**[-target-wwpn <text>] - FCP Target WWPN**
Selects the reservations that match the specified World Wide Port Name (WWPN).

**[-isid <text>] - Initiator Session ID**
Selects the reservations that match this parameter value.

**[-tpgroup-tag <integer>] - TPGroup Tag**
Selects the reservations that match the specified target portal group tag. The tag identifies the tpgroup the reservation was made over.

**[-third-party-initiator-name <text>] - Third Party Initiator Name**
Selects the reservations that match this parameter value (the initiator name that the reservation was made for). This is specific to third party reservation types, which is indicated by reservation-type-code.

### Examples

```
cluster1::*> lun persistent-reservation show -vserver vs_1 /vol/vol_1/lun_1
Key                     Protocol Type              Initiator Name
----------------------- -------- ----------------- ----------------------------
APTPL: true
a0:00:00:00:00:00:00:01 iscsi    write exclusive   iqn.1993-08.org.debian:01:fa752b8a5a3a
a0:00:00:00:00:00:00:01 iscsi    -                 iqn.1993-08.org.debian:01:fa752b8a5a3a
2 entries were displayed.
```

### lun portset commands

Manage portsets

### lun portset add

Add iSCSI/FCP LIFs to a portset

**Availability:** This command is available to cluster and Vserver administrators at the admin privilege level.

**Description**
This command adds existing iSCSI and FCP LIFs to a port set. To create a new port set, use the lun portset create command.

Use the network interface create command to create new LIFs.

**Parameters**

- **-vserver <Vserver Name> - Vserver Name**
  Specifies the Vserver.
Portset Name

Specifies the port set you want to add the LIFs to.

Port Name

Specifies the LIF name you want to add to the port set.

Examples

cluster1::> portset add -vserver vs1 -portset ps1 -port-name lif1

Related references

lun portset create on page 224
network interface create on page 335

lun portset create

Creates a new portset

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description

This command creates a new port set for FCP and iSCSI. The port set name can include a maximum of 96 characters. You can add LIFs to the new port set. If you do not add a LIF to the port set, you create an empty port set. To add LIFs to an existing port set, use the lun portset add command.

After you create a port set, you must bind the port set to an igroup so the host knows which FC or iSCSI LIFs to access. If you do not bind an igroup to a port set, and you map a LUN to an igroup, then the initiators in the igroup can access the LUN on any LIF on the Vserver.

Note: You cannot bind an igroup to an empty port set because the initiators in the igroup would have no LIFs to access the LUN.

Parameters

-vserver <Vserver Name> - Vserver Name

Specifies the Vserver.

-portset <text> - Portset Name

Specifies the name of the new port set. A port set name is a case-sensitive name that must contain one to 96 characters. Spaces are not allowed.

-port-name <port_name>, ... - LIF Or TPG Name

Specifies the name of the logical interface that you want to add to the portset you want to create.

-protocol {mixed|fcp|iscsi} - Protocol

Specifies if the portset protocol type is fcp, iscsi, or mixed. The default is mixed.

-fcp | -f [true] - FCP

Specifies FCP as the protocol type of the new port set.

-iscsi | -i [true]] - iSCSI

Specifies iSCSI as the protocol type of the new port set.

Examples

cluster1::> portset create -vserver vs1 -portset ps1 -protocol mixed

`lun portset add` on page 223

**lun portset delete**

Delete the portset

**Availability:** This command is available to `cluster` and `Vserver` administrators at the `admin` privilege level.

**Description**

This command deletes an existing port set. By default, you cannot delete a port set if it is bound to an initiator group. If a port set is bound to an initiator group, you can do one of the following:

• specify the `force` option to unbind the port set from the initiator group and delete the port set.

• use the `lun igroup unbind` command to unbind the port set from the initiator group. Then you can delete the port set.

**Parameters**

- `vserver <Vserver Name>` - Vserver Name
  
  Specifies the Vserver.

- `portset <text>` - Portset Name
  
  Specifies the port set you want to delete.

- `[-force | -f [true]]` - Force
  
  Forcibly unbinds the port set from the initiator group.

**Examples**

```
cluster1::> portset delete -vserver vs1 -portset ps1
```

Related references

`lun igroup unbind` on page 201

**lun portset remove**

Remove iSCSI/FCP LIFs from a portset

**Availability:** This command is available to `cluster` and `Vserver` administrators at the `admin` privilege level.
Description
This command removes a LIF from a port set.

You cannot remove the last LIF in a port set if the port set is bound to an initiator group (igroup). To remove the last LIF in a port set, use the `lun igroup unbind` command to unbind the port set from the igroup. Then you can remove the last LIF in the port set.

Parameters
- `vserver <Vserver Name>` - Vserver Name
  Specifies the Vserver.
- `portset <text>` - Portset Name
  Specifies the port set you want to remove a LIF from.
- `port-name <port_name>, ...` - LIF or TPG Name
  Specifies the LIF name you want to remove from the port set.

Examples
```
cluster1::> port set remove -vserver vs1 -portset psl -port-name lif1
```

Related references
- `lun igroup unbind` on page 201

lun portset show
Displays a list of portsets

Availability: This command is available to cluster and Vserver administrators at the `admin` privilege level.

Description
This command displays the LIFs in a port set. By default, the command displays all LIFs in all port sets.

Parameters
- `{ [-fields <fieldname>, ...]`
  If you specify the `[-fields <fieldname>, ...]` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.
- `[-instance]`
  If you specify the `-instance` parameter, the command displays detailed information about all fields.
- `[-vserver <Vserver Name>]` - Vserver Name
  Selects the port sets that match this parameter value.
- `[-portset <text>]` - Portset Name
  Selects the port sets that match this parameter value.
- `[-port-name <port_name>, ...]` - LIF Or TPG Name
  Selects the port sets that match this parameter value.
- `[-protocol {mixed | fcp | iscsi}]` - Protocol
  Selects the port sets that match this parameter value.
- `[-port-count <integer>]` - Number Of Ports
  Selects the port sets that match this parameter value.
-igroups <igroup>, ... - Bound To Igroups

Selects the port sets that match this parameter value.

**Examples**

```
cluster1::> lun portset show
Vserver   Portset      Protocol Port Names              Igroups
--------- ------------ -------- ----------------------- ------------
vs1       ps0          mixed    lif1, lif2              igroup1
          ps1          iscsi    lif3                    igroup2
          ps2          fcp      lif4                    
3 entries were displayed.
```

The example above displays all port sets.

```
cluster1::> lun portset show -port-count 0
Vserver   Portset      Protocol Port Names              Igroups
--------- ------------ -------- ----------------------- ------------
vs1       p1           iscsi    -                       -
```

The example above displays the port sets that contain zero LIFs.

```
cluster1::> lun portset show -protocol iscsi
Vserver   Portset      Protocol Port Names              Igroups
--------- ------------ -------- ----------------------- ------------
vs1       p1           iscsi    -                       -
vs1       iscsips      iscsi    lif1                    igroup1
2 entries were displayed.
```

The example above displays the port sets that have the iSCSI protocol.

```
cluster1::> lun portset show -port-name lif1
Vserver   Portset      Protocol Port Names              Igroups
--------- ------------ -------- ----------------------- ------------
vs1       iscsips      iscsi    lif1                    igroup1
```

**lun transition commands**

Manage LUN Transition from Data ONTAP 7-Mode

**lun transition show**

Display the status of LUN transition processing

**Availability:** This command is available to cluster administrators at the advanced privilege level.

**Description**

The `lun transition show` command displays information about the LUN transition processing status of volumes. If no parameters are specified, the command displays the following information about all volumes:

- Vserver name
- Volume name
- Transition status
Parameters

{[-fields <fieldname>, ...]
  If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

[-instance ]
  If you specify the -instance parameter, the command displays detailed information about all fields.

[-vserver <Vserver Name>]- Vserver Name
  Selects the volumes in the specified Vserver.

[-volume <volume name>]- Volume Name
  Selects the volumes with the specified name.

[-status {none|complete|failed|active}]- Transition Status
  Selects the volumes that match the specified transition status. The possible status values are:
  • active - The volume is in an active SnapMirror transition relationship and not yet transitioned.
  • complete - LUN transition has completed for the volume.
  • failed - LUN transition has failed for the volume.
  • none - The volume did not contain LUNs to transition from Data ONTAP 7-Mode.

[-vserver-uuid <UUID>] - Vserver UUID
  Selects the volumes in the Vserver that matches the specified UUID.

[-node <nodename>]- Filer ID
  Selects the volumes that match the specified node.

Examples

The following example displays LUN transition information for all volumes in a Vserver named vs1:

```
cluster1:~*> lun transition show -vserver vs1
  Vserver   Volume     Transition Status
          --------     -----------------
  vs1      vol0       none
           vol1       complete
           vol2       failed
           vol3       active
  4 entries were displayed.
```

lun transition start

Start LUN Transition Processing

Availability: This command is available to cluster administrators at the advanced privilege level.

Description

The lun transition start command starts LUN transition for the specified volume. Normally, transition is started automatically when snapmirror break is issued for the volume, this command allows restarting in the event automatic transitioning was interrupted or failed.
Parameters

- **vserver** <Vserver Name> - Vserver Name
  
  The name of the Vserver containing the volume. If only one data Vserver exists, you do not need to specify this parameter.

- **volume** <volume name> - Volume Name
  
  The name of the volume to restart LUN transition.

Examples

The following example starts LUN transition on a volume named `volume1` in a Vserver named `vs1`:

```
cluster1::*> lun transition start -vserver vs1 -volume volume1
```

Related references

* **snapmirror break** on page 635

**lun transition 7-mode commands**

The 7-mode directory

**lun transition 7-mode delete**

Delete an Untransitioned 7-Mode LUN

**Availability:** This command is available to `cluster` administrators at the `advanced` privilege level.

**Description**

The `lun transition 7-mode delete` command deletes an untransitioned LUN copied from a Data ONTAP 7-Mode system. This allows the admin to recover space from the volume for LUNs that may not be transitioned to clustered Data ONTAP without disrupting LUNs that have transitioned, for example, if the LUN is an unsupported OS type.

**Parameters**

- **vserver** <Vserver Name> - Vserver Name
  
  This specifies the name of the Vserver from which the LUN is to be deleted. If only one data Vserver exists, you do not need to specify this parameter.

- **path** <path> - LUN Path
  
  This specifies the path to the LUN to delete.

Examples

The following example deletes the LUN `/vol/vol1/lun1` in a Vserver named `vs1`:

```
cluster1::*> lun transition 7-mode delete -vserver vs1 -path /vol/vol1/lun1
```

**lun transition 7-mode show**

Display the 7-Mode LUN Inventory

**Availability:** This command is available to `cluster` administrators at the `advanced` privilege level.
Description
The `lun transition 7-mode show` command displays information about LUNs copied from a Data ONTAP 7-Mode system. If no parameters are specified, the command displays the following information about all 7-Mode LUNs:

- Vserver name
- LUN path
- Operating system type
- Size
- Whether or not the LUN has been transitioned to clustered Data ONTAP

Parameters

```
[-fields <fieldname>, ...]
```
If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

```
[-instance]
```
If you specify the `-instance` parameter, the command displays detailed information about all fields.

```
[-vserver <Vserver Name>] - Vserver Name
```
Selects the 7-Mode LUNs in the specified Vserver.

```
[-path <path>] - LUN Path
```
Selects the 7-Mode LUNs with the specified path.

```
[-volume <volume name>] - Volume Name
```
Selects the 7-Mode LUNs that match the specified volume.

```
[-ostype {vmware|hyper_v|windows_2008|windows_gpt|windows|linux|xen|solaris|solaris_efi|hpux|aix|netware|openvms}] - OS Type
```
Selects the 7-Mode LUNs that match the specified operating system type.

```
[-size <size>] - LUN Size
```
Selects the 7-Mode LUNs that match the specified size.

```
[-prefix-size <size>] - Prefix Stream Size
```
Selects the 7-Mode LUNs that match the specified prefix stream size.

```
[-suffix-size <size>] - Suffix Stream Size
```
Selects the 7-Mode LUNs that match the specified suffix stream size.

```
[-serial <text>] - Serial Number
```
Selects the 7-Mode LUNs that match the specified serial number for clustered Data ONTAP. LUNs where `is-transitioned` is `false` do not have a serial number assigned for clustered Data ONTAP.

```
[-uuid <UUID>] - UUID
```
Selects the 7-Mode LUNs that match the specified UUID for clustered Data ONTAP. LUNs where `is-transitioned` is `false` do not have a UUID assigned for clustered Data ONTAP.

```
[-serial-7-mode <text>] - 7-mode Serial Number
```
Selects the 7-Mode LUNs that match the specified serial number from 7-Mode.

```
[-is-transitioned {true|false}] - Transition Complete
```
Selects the 7-Mode LUNs that match the specified transition state. LUNs where this value is `true` have been transitioned and are available to be mapped for client access. LUNs where this value is `false` have not yet been transitioned and may not be mapped.
[-vserver-uuid <UUID>] - Vserver UUID
Selects the 7-Mode LUNs that match the specified Vserver UUID.

[-node <nodename>] - Node
Selects the 7-Mode LUNs that match the specified node name.

Examples
The following example displays a summary of all 7-Mode LUNs for the volume vol1 in a Vserver named vs1:

```
cluster1::*> lun transition 7-mode show -vserver vs1 -volume vol1

<table>
<thead>
<tr>
<th>Vserver</th>
<th>Path</th>
<th>Type</th>
<th>Size</th>
<th>Transitioned</th>
</tr>
</thead>
<tbody>
<tr>
<td>vs1</td>
<td>/vol/vol1/lun1</td>
<td>linux</td>
<td>10MB</td>
<td>false</td>
</tr>
<tr>
<td></td>
<td>/vol/vol1/lun2</td>
<td>linux</td>
<td>500MB</td>
<td>true</td>
</tr>
<tr>
<td></td>
<td>/vol/vol1/lun3</td>
<td>linux</td>
<td>500MB</td>
<td>true</td>
</tr>
</tbody>
</table>
8 entries were displayed.
```

The following example displays detailed information for the 7-Mode LUN /vol/vol1/lun2 in a Vserver named vs1:

```
cluster1::*> lun transition 7-mode show -vserver vs1 -path /vol/vol1/lun2

Vserver Name: vs1
LUN Path: /vol/vol1/lun2
Volume Name: vol1
OS Type: linux
LUN Size: 500MB
Prefix Stream Size: 0
Suffix Stream Size: 0
Serial Number: BCVvv$DLZu8g
UUID: f53d603b-9663-4567-9680-95c1a9cc6d9e
7-mode Serial Number: C4eqKotPI8Ui
Transition Complete: true
Vserver UUID: be4cc135-163f-11e3-931f-123478563412
Node: cluster-01
```

**metrocluster commands**

Manage MetroCluster

The metrocluster commands enable you to manage MetroCluster.

**metrocluster configure**

Configure MetroCluster and start DR mirroring for the node and its DR group

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**

The metrocluster configure command creates a MetroCluster configuration on either all the nodes in both MetroCluster clusters or solely on nodes in a DR group. The command configures a HA partner, DR partner, and a DR auxiliary partner for the nodes and also starts NVRAM mirroring between the configured DR partner nodes.

In MetroCluster, a DR group is a group of four nodes, two in each of the MetroCluster clusters:
- In the local cluster, a node and its HA partner,
• In the peer cluster, a node and its HA partner. These nodes are DR partners to the nodes in the local cluster.

In a two node MetroCluster configuration, a DR group is a group of two nodes, one in each of the MetroCluster clusters.

There can be several DR groups in the MetroCluster configuration. MetroCluster provides synchronous DR protection to all data sets belonging to nodes within a properly configured DR group.

Without the -node parameter, the metrocluster configure command configures all the DR groups in both the MetroCluster clusters.

With the -node mynode parameter, the command configures both the mynode node and its HA partner node from the local cluster, and its DR partner and DR auxiliary partner from the peer cluster.

Before running the metrocluster configure command, the aggregates and Vservers on each node must be prepared for the MetroCluster configuration. Each node should have:

• At least one non-root, mirrored aggregate of size greater than 10GB. This non-root aggregate should not have any volumes in it.

• No other non-root aggregates. Any other non-root, unmirrored aggregates and volumes should be deleted.

• No Vservers other than Vservers of type "node" or "admin." Any Vservers that are not of type "node" or "admin" should be deleted.

• A mirrored and healthy root aggregate.

After the command is successful all nodes in the local and remote clusters will have HA, DR, and DR auxiliary partners and NVRAM mirroring between the DR partners will be turned on. The same conditions apply before running the metrocluster configure -node mynode command, except that only one DR group is configured.

For a MetroCluster over IP configuration, the metrocluster configuration-settings commands must be completed before using the metrocluster configure command. The commands required to be completed are:

• metrocluster configuration-settings dr-group create
• metrocluster configuration-settings interface create
• metrocluster configuration-settings connection connect

Parameters

[-node-name (<nodename>|local)] - Node to Configure

This optional parameter specifies the name of a single node in the local cluster. The command creates MetroCluster configuration on the local node specified by this parameter and the three other nodes belonging to the same DR group.

[-refresh (true|false)] - Refresh Configuration (privilege: advanced)

This optional parameter specifies if the node partner configuration steps should be done again. Not specifying this parameter will cause the MetroCluster configuration to continue using the current node partner information.

[-allow-with-one-aggregate (true|false)] - Override the Two Data Aggregates Requirement (privilege: advanced)

This optional parameter specifies if MetroCluster configuration should be allowed with only one data aggregate in each cluster. This option has no effect if two or more aggregates are present.

Examples

The following example shows the creation of the MetroCluster configuration for a single DR group:

```
clusA::> metrocluster show
Cluster          Configuration State     Mode
----------------- ---------------------- ------
Local: clusA       not-configured      -
```
Remote: clusB                  not-configured         -

clusA::> metrocluster node show
  DR Group Cluster Node       Configuration     DR State      Mirroring Mode
  ----- ------- -------------- ------------------ -------------- --------- -------------------
-     clusA clusA-01           ready to configure
     clusA-02           ready to configure
     clusA-03           ready to configure
     clusA-04           ready to configure
-         -
4 entries were displayed.

clusA::> metrocluster configure -node clusA-01
  [Job 45] Job succeeded: Configure is successful

clusA::> metrocluster show
  Cluster                        Configuration State    Mode
  ------------------------------ ---------------------- ------------------------
  Local: clusA                  partially-configured   normal
  Remote: clusB                  partially-configured   normal

clusA::> metrocluster node show
  DR Group Cluster Node       Configuration     DR State      Mirroring Mode
  ----- ------- -------------- ------------------ -------------- --------- -------------------
-     clusA clusA-03           ready to configure
     clusA-04           ready to configure
-         -
1     clusA clusA-01           configured     enabled   normal
     clusA-02           configured     enabled   normal
     clusB clusB-01           configured     enabled   normal
     clusB-02           configured     enabled   normal
6 entries were displayed.

The following example shows the creation of the MetroCluster configuration for all DR groups:

clusA::> metrocluster show
  Cluster                        Configuration State    Mode
  ------------------------------ ---------------------- ------------------------
  Local: clusA                  not-configured         -
  Remote: clusB                  not-configured         -

clusA::> metrocluster node show
  DR Group Cluster Node       Configuration     DR State      Mirroring Mode
  ----- ------- -------------- ------------------ -------------- --------- -------------------
-     clusA clusA-01           ready to configure
     clusA-02           ready to configure
     clusA-03           ready to configure
     clusA-04           ready to configure
-         -
4 entries were displayed.

clusA::> metrocluster configure
  [Job 45] Job succeeded: Configure is successful

clusA::> metrocluster show
  Cluster                        Configuration State    Mode
  ------------------------------ ---------------------- ------------------------
  Local: clusA                  configured             normal
  Remote: clusB                  configured             normal

clusA::> metrocluster node show
  DR Group Cluster Node       Configuration     DR State      Mirroring Mode
  ----- ------- -------------- ------------------ -------------- --------- -------------------
1     clusA clusA-01           configured     enabled   normal
8 entries were displayed.

metrocluster heal

Heal DR data aggregates and DR root aggregates

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The metrocluster heal command heals DR data aggregates and DR root aggregates in preparation for a DR switchback. You must issue this command twice to complete the two phases of the healing process: first to heal the aggregates by resynchronizing the mirrored plexes and then to heal the root aggregates by switching them back to the disaster site. The DR partner nodes must be powered off and remote disk shelves must be powered on before running this command.

Parameters
-phase {aggregates|root-aggregates} - MetroCluster Healing Phase

This parameter specifies the healing phase. The first phase, aggregates, heals aggregates by resynchronizing mirrored plexes. The second phase, root-aggregates, heals the root aggregates of partner nodes. Heating root aggregates switches them back to the disaster site, allowing the site to boot up.

[-override-vetoes [true]] - Override All Soft Vetoes

This optional parameter overrides almost all heal operation soft vetoes. If this optional parameter is set to true, the system overrides subsystem soft vetoes that might prevent the heal operation. Hard vetoes cannot be overridden and can still prevent the switchback operation.

Examples

The following example performs the healing of both the aggregates and root aggregates:

```
cluster1::> metrocluster heal -phase aggregates
[Job 136] Job succeeded: Heal Aggregates is successful

cluster1::> metrocluster heal -phase root-aggregates
[Job 137] Job succeeded: Heal Root Aggregates is successful
```
**metrocluster modify**

Modify MetroCluster configuration options

**Availability:** This command is available to `cluster` administrators at the `admin` privilege level.

**Description**
The `metrocluster modify` command modifies MetroCluster parameters for nodes in the MetroCluster configuration.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-auto-switchover-failure-domain</code></td>
<td>Cluster Level AUSO Option</td>
</tr>
<tr>
<td></td>
<td>This parameter specifies the configuration of automatic switchover.</td>
</tr>
<tr>
<td></td>
<td>Modifying <code>auto-switchover-failure-domain</code> is not supported on a MetroCluster over IP configuration.</td>
</tr>
<tr>
<td></td>
<td>The parameter values are:</td>
</tr>
<tr>
<td></td>
<td>• auso-on-cluster-disaster - triggers an unplanned switchover if all nodes in a DR cluster are down.</td>
</tr>
<tr>
<td></td>
<td>• auso-on-dr-group-disaster - triggers an unplanned switchover if both nodes of a DR group are down.</td>
</tr>
<tr>
<td></td>
<td>• auso-disabled - automatic switchover is disabled.</td>
</tr>
<tr>
<td></td>
<td>On a MetroCluster over IP configuration, <code>auto-switchover-failure-domain</code> is set to <code>auso-disabled</code>; otherwise, it is set to <code>auso-on-cluster-disaster</code>.</td>
</tr>
<tr>
<td></td>
<td>A change to the parameter affects only the local cluster where the <code>metrocluster modify</code> command is used.</td>
</tr>
<tr>
<td>`-node-name {&lt;nodename&gt;</td>
<td>local}`</td>
</tr>
<tr>
<td></td>
<td>This parameter is used to specify the node in the cluster for which the parameter needs to be modified.</td>
</tr>
<tr>
<td><code>-automatic-switchover-onfailure [true]</code></td>
<td>Node Level AUSO Option</td>
</tr>
<tr>
<td></td>
<td>This parameter is used to enable automatic switchover on node failures.</td>
</tr>
<tr>
<td></td>
<td>The <code>automatic-switchover-onfailure</code> parameter is not supported on a MetroCluster over IP configuration.</td>
</tr>
<tr>
<td></td>
<td>All nodes in a MetroCluster configuration must have this option enabled to enable automatic switchover on failure.</td>
</tr>
</tbody>
</table>

**Examples**
The following example shows the output of Metrocluster modification done on a node:

```plaintext
clusA:~$> metrocluster modify -node-name clusA-01 -node-object-limit on
[Job 168] Job succeeded: Modify is successful
clusA:~$> metrocluster modify -node-name clusA-01 -automatic-switchover-onfailure false
[Job 308] Job succeeded: Modify is successful
clusA:~$> metrocluster modify -auto-switchover-failure-domain auso-on-cluster-disaster
[Job 308] Job succeeded: Modify is successful
```

`metrocluster configure` on page 231
metrocluster show

Display MetroCluster configuration information

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The metrocluster show command displays configuration information for the pair of clusters configured in MetroCluster.

This command displays the following details about the local cluster and the DR partner cluster:

- Configuration State: This field specifies the configuration state of the cluster.
- Mode: This field specifies the operational mode of the cluster.
- AUSO Failure Domain: This field specifies the AUSO failure domain of the cluster.

Parameters

[-periodic-check-status ]

If this option is used the MetroCluster periodic check status is displayed.

Examples

The following example shows the output of the command before MetroCluster configuration is done:

```
clusA::> metrocluster show
Cluster | Entry Name | State
-------- | ---------- | ------
Local: clusA | Configuration State | not-configured
            | Mode | -
            | AUSO Failure Domain | -
Remote: clusB | Configuration State | not-configured
            | Mode | -
            | AUSO Failure Domain | -
```

The following example shows the output of the command after MetroCluster configuration is done only for some DR groups:

```
clusA::> metrocluster show
Cluster | Entry Name | State
-------- | ---------- | ------
Local: clusA | Configuration State | partially-configured
            | Mode | -
            | AUSO Failure Domain | -
Remote: clusB | Configuration State | partially-configured
            | Mode | -
            | AUSO Failure Domain | -
```

The following example shows the output of the command after MetroCluster configuration is done:

```
clusA::> metrocluster show
Cluster | Entry Name | State
-------- | ---------- | ------
Local: clusA
```
The following example shows the output of the command in switchover mode:

```
clusA::> metrocluster show
Cluster                        Entry Name           State
------------------------------- -------------------  ---------------------
Local: clusA
  Configuration State  configured
  Mode  switchover
  AUSO Failure Domain  auso-on-cluster-disaster
Remote: clusB
  Configuration State  not reachable
  Mode  -
  AUSO Failure Domain  not-reachable
```

The following example shows the output of the command when `-periodic-check-status` option is used:

```
clusA::> metrocluster show -periodic-check-status
Cluster                        Periodic Check Enabled
------------------------------ ----------------------
Local: clusA                  true
Remote: clusB                  true
```

**metrocluster switchback**

Switch back storage and client access

**Availability:** This command is available to cluster administrators at the `admin` privilege level.

**Description**

The `metrocluster switchback` command initiates the switchback of storage and client access from nodes in the DR site to their home nodes. The home nodes and storage shelves must be powered on and reachable by nodes in the DR site. The `metrocluster heal -phase aggregates` and `metrocluster heal -phase root-aggregates` commands must have successfully completed before running the `metrocluster switchback` command.

**Parameters**

`[-override-vetoes | -f [true]]` - Override All Soft Vetoes

This optional parameter overrides all switchback operation soft vetoes. If this optional parameter is used, the system overrides subsystem soft vetoes that might prevent the switchback operation. Hard vetoes cannot be overridden and can still prevent the switchover operation.
Simulate Switchback (privilege: advanced)

If this optional parameter is used, the system runs a simulation of the switchback operation to make sure all the prerequisites for the operation are met. This parameter cannot be used with switchback operations performed for switching back left-behind aggregates or for retrying a partially successful switchback.

Examples

The following is an example of how to start the switchback operation.

```
clusA::> metrocluster switchback
```

Related references

`metrocluster heal` on page 234

**metrocluster switchover**

Switch over storage and client access

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**

The `metrocluster switchover` command initiates the switchover of storage and client access from the source cluster to the disaster recovery (DR) site. This command is to be used after a disaster that renders all the nodes in the source cluster unreachable and powered off. It can also be used for negotiated switchover when the outage of the source cluster is anticipated as in cases such as disaster recovery testing or a site going offline for maintenance. If a switchover operation previously failed on certain nodes on the DR site then issuing the command retries the operation on all of those nodes.

**Parameters**

```
[-simulate [true]] - Simulate Negotiated Switchover (privilege: advanced)
```

If this optional parameter is used, the system runs a simulation of the negotiated switchover operation to make sure all the prerequisites for the operation are met. This parameter cannot be used with switchover with the `-forced-on-disaster` parameter.

```
[-forced-on-disaster [true]] - Force Switchover on Disaster
```

This optional parameter forces a switchover on disaster. This parameter should be used if all the nodes on the disaster stricken site are powered off and unreachable. In the absence of this parameter, the command attempts to perform a negotiated switchover operation.

```
[-force-nvfail-all [true]] - Sets in-nvfailed-state on All Volumes (privilege: advanced)
```

If this parameter is used, the switchover command will set the in-nvfailed-state parameter to true for all volumes being switched over and will set the `-dr-force-nvfail` parameter to true for any volumes that do not already have it enabled. This parameter has no effect when performing a negotiated switchover.

```
[-retry-failed-nodes <Node name>, ...] - Nodes to Switchover
```

This optional parameter takes the list of nodes that previously failed the switchover operation and it retries the switchover operation on each of the nodes. This parameter is applicable only for a switchover with the `-forced-on-disaster` parameter.

```
[-override-vetoes [true]] - Override All Soft Vetoes
```

This optional parameter overrides all switchover operation soft vetoes. If this parameter is used, the system overrides all subsystem soft vetoes that might prevent the switchover operation. Hard vetoes cannot be overridden and can still prevent the switchover operation.
Examples
When a disaster strikes one site, the `metrocluster switchover` command is issued on the disaster recovery site as follows:

```
cluster1::> metrocluster switchover -forced-on-disaster true
```

Warning: MetroCluster switchover is a Disaster Recovery operation that could cause some data loss. The cluster on the other site must either be prevented from serving data or be simply powered off (nodes and disk shelves).

The following nodes (cluster1-01 cluster1-02) will participate in the switchover operation.

Do you want to continue? {y|n}: y

Queued job. Use 'metrocluster operation show' to check status of the DR operation.

```
cluster1::> metrocluster operation show
Operation: switchover
  State: successful
  Start time: 10/3/2013 22:11:47
  End time: 10/3/2013 22:11:53
  Errors: -
```

`metrocluster check commands`
Check MetroCluster configuration and display results

`metrocluster check disable-periodic-check`
Disable Periodic Check

**Availability:** This command is available to `cluster` administrators at the `admin` privilege level.

**Description**
The `metrocluster check disable-periodic-check` command disables the periodic checking of the MetroCluster configuration.

After this command is run, the MetroCluster Check job will be prevented from periodically checking the configuration for errors.

Examples
```
clusA::> metrocluster check disable-periodic-check
```

Related references
- `metrocluster check enable-periodic-check` on page 240
**metrocluster check enable-periodic-check**

Enable Periodic Check

**Availability:** This command is available to cluster administrators at the `admin` privilege level.

**Description**
The `metrocluster check enable-periodic-check` command enables the periodic checking of the MetroCluster configuration.

After this command is run, the MetroCluster Check job will be able to run in the background and periodically check the configuration for errors.

**Examples**

```
clusA::> metrocluster check enable-periodic-check
```

**Related references**

`metrocluster check disable-periodic-check` on page 239

**metrocluster check run**

Check the MetroCluster setup

**Availability:** This command is available to cluster administrators at the `admin` privilege level.

**Description**
The `metrocluster check run` command performs checks on the MetroCluster configuration and reports configuration errors if any.

To run this command, at least one DR group needs to be configured. The command checks the following parts of the configuration:

**Node Configuration:**

- node-reachable: This check verifies that the node is reachable.
- metrocluster-ready: This check verifies that the node is ready for MetroCluster configuration.
- local-ha-partner: This check verifies that the HA partner node is in the same cluster.
- ha-mirroring-on: This check verifies that HA mirroring for the node is configured.
- symmetric-ha-relationship: This check verifies that the relationship between the node and its HA partner is symmetric.
- remote-dr-partner: This check verifies that the DR partner node is in the remote cluster.
- dr-mirroring-on: This check verifies that DR mirroring for the node is configured.
- symmetric-dr-relationship: This check verifies that the relationship between the node and its DR partner is symmetric.
- remote-dr-auxiliary-partner: This check verifies that the DR auxiliary partner node is in the remote cluster.
- symmetric-dr-auxiliary-relationship: This check verifies that the relationship between the node and its DR auxiliary partner is symmetric.
- storage-failover-enabled: This check verifies that storage failover is enabled.
• has-intercluster-lif: This check verifies that the node has an intercluster LIF.

• node-object-limit: This check verifies that the node object limit option for the node is turned on.

Aggregate Configuration:

• mirroring-status: This check verifies that the aggregate is mirrored.

• disk-pool-allocation: This check verifies that the disks belonging to this aggregate have been correctly allocated to the right pools.

At the end of the check the command displays a summary of the results. This summary output can be viewed again by running `metrocluster check show`. If any of the rows in this output show any warnings more details can be viewed by running the `metrocluster check show` command for that component.

Parameters

`[-skip-dr-simulation {true|false}]` - Skip the DR Readiness Checks (privilege: advanced)

If this optional parameter is set to true, the switchover and switchback simulations are not run.

Examples

The following example shows the execution of the command when there are no warnings:

```
clusA::> metrocluster check run

Component | Result
------------- | --------
nodes       | ok       
clusters    | ok       
lifs        | ok       
config-replication | ok
aggregates  | ok       

5 entries were displayed.

Command completed. Use the "metrocluster check show -instance" command or sub-commands in "metrocluster check" directory for detailed results.
```

The following example shows the execution of the command when there are some warnings:

```
clusA::> metrocluster check run

Component | Result
------------- | --------
nodes       | warning 
clusters    | ok       
lifs        | ok       
config-replication | ok
aggregates  | ok       

5 entries were displayed.

Command completed. Use the "metrocluster check show -instance" command or sub-commands in "metrocluster check" directory for detailed results.
```

Related references

`metrocluster check show` on page 242
**metrocluster check show**

Show the results of the last instance of MetroCluster check

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**

The `metrocluster check show` command displays the results of the `metrocluster check run` command.

This command displays the high-level verification results for each of the components. If there are any errors for a component, running the show command for that component (for example `metrocluster check node show` or `metrocluster check aggregate show`) will display more information about the warning.

**Note:** Please note that this command does not run the checks but only displays the results of checks. To look at the latest results, run the `metrocluster check run` command and then run this command.

**Parameters**

```
[-fields <fieldname>, ...]
```

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

```
[-instance]
```

If you specify the `-instance` parameter, the command displays detailed information about all fields.

```
[-timestamp <MM/DD/YYYY HH:MM:SS>] - Time of Check
```

This is the time at which the `metrocluster check run` command was last run in this cluster and these results were produced. If this parameter is specified, only rows with this timestamp will be displayed.

```
[-component <MetroCluster Check Components>] - Name of the Component
```

This is the name of the component. If this parameter is specified, only rows with this component will be displayed.

```
[-result {ok|warning|not-run|not-applicable}] - Result of the Check
```

This is the result of the check for the component. If this parameter is specified, only rows with this result will be displayed.

```
[-additional-info <text>] - Additional Information/Recovery Steps
```

This is the additional info for the verification for this component. This field will have detailed information about the warning and recovery steps. If this parameter is specified, only rows with this additional info will be displayed.

**Examples**

The following example shows the execution of the command when there are no warnings:

```
clusA::> metrocluster check show

<table>
<thead>
<tr>
<th>Component</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>nodes</td>
<td>ok</td>

<td>ok</td>
</tr>
<tr>
<td>lifs</td>
<td>ok</td>
</tr>
<tr>
<td>config-replication</td>
<td>ok</td>
</tr>
<tr>
<td>aggregates</td>
<td>ok</td>
</tr>
</tbody>
</table>
```

The following example shows the execution of the command when there are some warnings:

```
clusA::> metrocluster check show
Component           Result
------------------- ---------
nodes               warning
clusters            ok
lifs                ok
config-replication  ok
aggregates          ok
connections         ok
6 entries were displayed.
```

The following example shows the execution of the command with -instance option:

```
clusA::> metrocluster check show -instance

Name of the Component: nodes
Result of the Check: warning
Additional Information/Recovery Steps:

metrocluster check aggregate commands

The aggregate directory

metrocluster check aggregate show

Show results of MetroCluster check for aggregates

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The metrocluster check aggregate show command displays the results of aggregate checks performed by the metrocluster check run command.

The command verifies the following aspects of the configuration of all aggregates in MetroCluster:

• mirroring-status: This check verifies that the aggregate is mirrored.
• disk-pool-allocation: This check verifies that the disks belonging to this aggregate have been correctly allocated to the right pools.

Additional information about the warnings (if any) and recovery steps can be viewed by running the command with the -instance option.

Parameters

[-fields <fieldname>, ...]
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use `-fields ?' to display the fields to specify.

[-instance ]
If you specify the -instance parameter, the command displays detailed information about all fields.

[-node <Node name>] - Node Name
This is the name of the node for which the check was run. If this parameter is specified, only rows with this node will be displayed.

[-aggregate <aggregate name>] - Name of the Aggregate
This is the name of the aggregate for which the check was run. If this parameter is specified, only rows with this aggregate will be displayed.

[-check <MetroCluster Aggregate Check>] - Type of Check
This is the type of the check performed. If this parameter is specified, only rows with this check will be displayed.

[-cluster <Cluster name>] - Name of Cluster
This is the name of the cluster the node belongs to. If this parameter is specified, only rows with this cluster will be displayed.

[-result {ok|warning|not-run|not-applicable}] - Result of the Check
This is the result of the check. If this parameter is specified, only rows with this result will be displayed.

[-additional-info <text>, ...] - Additional Information/Recovery Steps
This is additional information about the check. This field has more information and recovery steps for the warning. If this parameter is specified, only rows with this additional info will be displayed.

Examples
The following example shows the execution of the command in a MetroCluster configuration with two nodes per cluster:
clusA::> metrocluster check aggregate show

metrocluster check cluster commands
The cluster directory

metrocluster check cluster show
Show results of MetroCluster check for the cluster components

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The metrocluster check cluster show command displays the results of cluster checks performed by the metrocluster check run command.
The command displays the results of the following cluster configuration checks:

- **negotiated-switchover-ready**: This check verifies that the cluster is ready for a negotiated switchover operation.
- **switchback-ready**: This check verifies that the cluster is ready for a switchback operation.
- **job-schedules**: This check verifies that the job schedules between the local and remote clusters are consistent.
- **licenses**: This check verifies that the licenses between the local and remote clusters are consistent.
- **periodic-check-enabled**: This check verifies that the periodic MetroCluster Check Job is enabled.
- **onboard-key-management**: This check verifies that the Onboard Key Management hierarchies are consistent.
- **external-key-management**: This check verifies that the External Key Management configurations are consistent.

Additional information about the warnings (if any) and recovery steps can be viewed by running the command with the `-instance` parameter.

### Parameters

```
[-fields <fieldname>, ...]
```

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

```
[-instance]
```

If you specify the `-instance` parameter, the command displays detailed information about all fields.

```
[-check {negotiated-switchover-ready|switchback-ready|job-schedules|licenses|periodic-check-enabled|onboard-key-management|external-key-management}] - Type of Check
```

This is the type of the check performed. If this parameter is specified, only rows with this check will be displayed.

```
[-cluster <Cluster name>] - Cluster Name
```

This is the name of the cluster the check results apply to. If this parameter is specified, only rows matching the specified cluster will be displayed.

```
[-result {ok|warning|not-run|not-applicable}] - Result of the Check
```

This is the result of the check. If this parameter is specified, only rows with this result will be displayed.

```
[-additional-info <text>] - Additional Information/Recovery Steps
```

This is additional information about the check. This field has more information and recovery steps for the warning. If this parameter is specified, only rows with this additional info will be displayed.

### Examples

The following example shows the execution of the command in a MetroCluster configuration:

```
clusA::> metrocluster check cluster show
Last Checked On: 11/29/2018 17:15:00

<table>

metrocluster check config-replication commands

Display MetroCluster check configuration replication status

metrocluster check config-replication show

Display MetroCluster config-replication status information

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The metrocluster check config-replication show command displays the results of MetroCluster configuration replication.

The command verifies the following aspects of MetroCluster configuration replication:

• Enabled: Verifies that MetroCluster configuration replication is enabled on the cluster.
• Running: Verifies that MetroCluster configuration replication is running on the cluster.
• Remote Heartbeat: Verifies that the MetroCluster configuration replication heartbeat with the remote cluster is healthy.
• Last Heartbeat Sent: Prints the timestamp of the last MetroCluster configuration replication heartbeat sent to the remote cluster.
• Last Heartbeat Received: Prints the timestamp of the last MetroCluster configuration replication heartbeat received from the remote cluster.
• Storage Status: Verifies that MetroCluster configuration replication storage is healthy.
• Storage In Use: Prints the location of MetroCluster configuration replication storage.
• Storage Remarks: Prints the underlying root cause for non healthy MetroCluster configuration storage.
• Vserver Streams: Verifies that MetroCluster configuration replication Vserver streams are healthy.
• Cluster Streams: Verifies that MetroCluster configuration replication Cluster streams are healthy.

Additional information about the warnings (if any) and recovery steps can be viewed by running the command with the -instance option.
Parameters

[-instance]

If you specify the -instance parameter, the command displays detailed information about all fields.

Examples

The following example shows the output of `metrocluster check config-replication show`:

```
clusA::metrocluster check config-replication> show
  Enabled: true
  Running: true
  Remote Heartbeat: ok
  Last Heartbeat Sent: 12/12/2013 14:24:59
  Last Heartbeat Received: 12/12/2013 14:25:00
  Storage Status: ok
  Storage In Use: Cluster-wide Volume: MDV_CRS_1bc7134a5ddf11e3b63f123478563412_A
  Storage Remarks: -
  Vserver Streams: ok
  Cluster Streams: ok
```

`metrocluster check config-replication show-aggregate-eligibility`

**Availability:** This command is available to `cluster` administrators at the `admin` privilege level.

**Description**

The `metrocluster check config-replication show-aggregate-eligibility` command displays the MetroCluster configuration replication aggregate eligibility.

**Parameters**

```
[-fields <fieldname>, ...]
```

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

```
[[-instance]]
```

If you specify the `-instance` parameter, the command displays detailed information about all fields.

```
[-aggregate <aggregate name>] - Aggregate
```

This is the aggregate name. If this parameter is specified, only rows with this aggregate will be displayed.

```
[-hosted-configuration-replication-volumes <volume name>, ...] - Currently Hosted Configuration Replication Volumes
```

This is the list of the configuration replication volumes hosted on this aggregate. If this parameter is specified, only rows with these configuration replication volumes will be displayed.

```
[-is-eligible-to-host-additional-volumes {true|false}] - Eligibility to Host Another Configuration Replication Volume
```

This is the eligibility of the aggregate to host additional configuration replication volumes. If this parameter is specified, only rows with this eligibility will be displayed.
[-comment <text>] - Comment for Eligibility Status

This is a comment regarding the eligibility of the aggregate to host configuration replication volumes. If this parameter is specified, only rows with this comment will be displayed.

Examples

The following example shows the execution of the command in a MetroCluster configuration with thirteen aggregates in the cluster:

```
clusA::metrocluster check config-replication> show-aggregate-eligibility
Aggregate    Hosted Config Replication Vols             Host Addl Vols Comments

`metrocluster check config-replication show-capture-status`

Display MetroCluster capture status information

**Availability:** This command is available to cluster administrators at the `advanced` privilege level.

**Description**

The `metrocluster check config-replication show-capture-status` command indicates whether or not a configuration change that would prevent a negotiated switchover is currently being captured for replication.

**Examples**

The following example shows the execution of the command in a MetroCluster configuration when capture is not in progress:

```
cluster1::*> metrocluster check config-replication show-capture-status
Is Capture in Progress: false
```

**metrocluster check connection commands**

Display the check results of connections for nodes in a MetroCluster over IP configuration

**metrocluster check connection show**

Display the check results of connections for nodes in a MetroCluster over IP configuration

**Availability:** This command is available to `cluster` administrators at the `admin` privilege level.

**Description**

The `metrocluster check connection show` command displays the check results of connections for nodes in a MetroCluster over IP configuration.

**Parameters**

```
{ [-fields <fieldname>, ...]
  If you specify the -fields <fieldname>, ... parameter, the command displays only the fields that you specify.

  | [instance ]
  If this parameter is specified, the command displays detailed information about all entries.

  [-dr-group-id <integer> ] - DR Group ID
  If this parameter is specified, the command displays information for the matching DR group.

  [-cluster-uuid <UUID> ] - Cluster UUID
  If this parameter is specified, the command displays information for the matching cluster specified by uuid.

  [-cluster <Cluster name> ] - Cluster Name
  If this parameter is specified, the command displays information for the matching cluster.

  [-node-uuid <UUID> ] - Node UUID
  If this parameter is specified, the command displays information for the matching node specified by uuid.

  [-node <text> ] - Node Name
  If this parameter is specified, the command displays information for the matching nodes.

  [-home-port {<netport>|<ifgrp>}] - Home Port
  If this parameter is specified, the command displays information for the matching home-port.

  [-relationship-type <Roles of MetroCluster Nodes>] - Relationship Role Type
  If this parameter is specified, the command displays information for the matching relationship-type.

  [-source-address <IP Address> ] - Source Network Address
  If this parameter is specified, the command displays information for the matching source address.

  [-destination-address <IP Address> ] - Destination Network Address
  If this parameter is specified, the command displays information for the matching destination address.

  [-partner-cluster-uuid <UUID> ] - Partner Cluster UUID
  If this parameter is specified, the command displays information for the matching partner-cluster-uuid.

  [-partner-node-uuid <UUID> ] - Partner Node UUID
  If this parameter is specified, the command displays information for the matching partner-node-uuid.
```
[-partner-node <text>] - Partner Node Name
    If this parameter is specified, the command displays information for the matching partner-node.

[-partner-type <text>] - Partner Relationship Type
    If this parameter is specified, the command displays information for the matching partner-type.

[-config-state <text>] - Configuration State
    If this parameter is specified, the command displays information for the matching config-state.

[-config-error-info <text>] - Configuration Error Information
    If this parameter is specified, the command displays information for the matching config-error-info.

[-check-result {ok|warning|not-run|not-applicable}] - Check Connection Result
    If this parameter is specified, the command displays information for the matching check-result.

[-check-ping-error-info <text>] - Check Connection Ping Error Info
    If this parameter is specified, the command displays information for the matching check-ping-error-info.

[-check-mtu-size-error-info <text>] - Check Connection MTU Size Error Info
    If this parameter is specified, the command displays information for the matching check-mtu-size-error-info.

[-check-storage-error-info <text>] - Check Connection Storage Error Info
    If this parameter is specified, the command displays information for the matching check-storage-error-info.

Examples

The following example shows the output of the metrocluster check connection show command:

```

```
metrocluster check lif commands

Display LIF placement check results in MetroCluster configuration

metrocluster check lif repair-placement

Repair LIF placement for the sync-source Vserver LIFs in the destination cluster

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The metrocluster check lif repair-placement command reruns LIF placement for those LIFs displayed by the metrocluster check lif show command. This command is expected to be run after the admin manually rectifies the LIF placement failures displayed in the metrocluster check lif show command output. The command is successful if the LIF placement rerun does not encounter any LIF placement failure. This is to be confirmed by subsequent running of the metrocluster check lif show.

Parameters
-vserver <Vserver Name> - sync-source Vserver Name

This is the name of the sync source Vserver that has LIF placement failures as reported by the metrocluster check lif show command. This input ensures that the command is run on the specified Vserver.
[-lif <lif-name>] - Logical Interface Name

This is the Logical Interface name that belongs to the sync source Vserver that has a LIF placement failure in the destination cluster as reported by the `metrocluster check lif show` command. This input ensures that the command is run on the specified LIF only.

Examples

The following example shows the execution of the command with a sync source Vserver and a LIF specified:

```
clusA::> metrocluster check lif repair-placement -vserver vs1.example.com -lif fcplif1
Command completed. Run the "metrocluster check lif show" command for results.
clusA::> metrocluster check lif repair-placement -vserver vs1.example.com -lif iscsilif1
Command completed. Run the "metrocluster check lif show" command for results.
```

The following example shows the execution of the command with only a sync-source Vserver specified:

```
clusA::> metrocluster check lif repair-placement -vserver vs1.example.com
Command completed. Run the "metrocluster check lif show" command for results.
clusA::>
```

`metrocluster check lif show`

Show results of MetroCluster check results for the data LIFs

**Availability:** This command is available to cluster administrators at the `admin` privilege level.

**Description**

The `metrocluster check lif show` command displays the LIF placement failures in the MetroCluster configuration. The command verifies the following aspects of the LIF placements of all the data LIFs in Metrocluster:

- lif-placed-on-dr-node: This check verifies that the LIF is placed on DR partner node.
- port-selection: This check verifies that the LIF is placed on correct port.

The LIF placement failures are mostly fabric/network connectivity issues that require manual intervention. Once the connectivity issues are resolved manually, the admin is expected to run `metrocluster check lif repair-placement` command to resolve the LIF placement issues for the sync source Vserver.

Additional information about the warnings (if any) and recovery steps can be viewed by running the command with the `-instance` option.

**Parameters**

```
{ [-fields <fieldname>, ...]
   If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.
 |
[-instance ]
   If you specify the `-instance` parameter, the command displays detailed information about all fields.
```

`metrocluster check commands`
[-cluster <Cluster name>] - Name of the Cluster
This is the name of the cluster the LIF belongs to. If this parameter is specified, only rows with this cluster will be displayed.

[-vserver <text>] - Name of the Vserver
This is the name of the Vserver in the MetroCluster configuration

[-lif <lif-name>] - Name of the Lif
This is the name of the LIF.

[-check <MetroCluster LIF placement Check>] - Description
This is the type of the check performed. If this parameter is specified, only rows with this check will be displayed.

[-result {ok|warning|not-run|not-applicable}] - Result of the Check
This is the result of the check performed. If this parameter is specified, only rows with this result will be displayed.

[-additional-info <text>] - Additional Information/Recovery Steps
This is additional information about the check. This field has more information and recovery steps for the warning. If this parameter is specified, only rows with this additional info will be displayed.

Examples
The following example shows the execution of the command in a MetroCluster configuration with two nodes per cluster:

metrocluster check node commands
The node directory
**metrocluster check node show**

Show results of MetroCluster check for nodes

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**

The `metrocluster check node show` command displays the results of node checks performed by the `metrocluster check run` command.

The command displays the results of the following node configuration checks:

- **node-reaching:** This check verifies that the node is reachable.
- **metrocluster-ready:** This check verifies that the node is ready for MetroCluster configuration.
- **local-ha-partner:** This check verifies that the HA partner node is in the same cluster.
- **ha-mirroring-on:** This check verifies that HA mirroring for the node is configured.
- **ha-mirroring-op-state:** This check verifies that the HA mirroring operation is online.
- **symmetric-ha-relationship:** This check verifies that the relationship between the node and its HA partner is symmetric.
- **remote-dr-partner:** This check verifies that the DR partner node is in the remote cluster.
- **dr-mirroring-on:** This check verifies that DR mirroring for the node is configured.
- **dr-mirroring-op-state:** This check verifies that the DR mirroring operation is online.
- **symmetric-dr-relationship:** This check verifies that the relationship between the node and its DR partner is symmetric.
- **remote-dr-auxiliary-partner:** This check verifies that the DR auxiliary partner node is in the remote cluster.
- **symmetric-dr-auxiliary-relationship:** This check verifies that the relationship between the node and its DR auxiliary partner is symmetric.
- **storage-failover-enabled:** This check verifies that storage failover is enabled.
- **has-intercluster-lif:** This check verifies that the node has an intercluster LIF.
- **node-object-limit:** This check verifies that the node object limit option for the node is turned on.
- **automatic-uso:** This check verifies that the automatic USO option for the node is enabled.

Additional information about the warnings (if any) and recovery steps can be viewed by running the command with the `-instance` parameter.

**Parameters**

```
[-fields <fieldname>, ...]
```

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `'-fields ?'` to display the fields to specify.

```
[-instance]
```

If you specify the `-instance` parameter, the command displays detailed information about all fields.

```
[-node <Node name>] - Node Name
```

This is the name of the node for which the check was run. If this parameter is specified, only rows with this node will be displayed.
[-check `<MetroCluster Node Check>`] - Type of Check

This is the type of the check performed. If this parameter is specified, only rows with this check will be displayed.

[-cluster `<Cluster name>`] - Cluster Name

This is the name of the cluster the node belongs to. If this parameter is specified, only rows with this cluster will be displayed.

[-result `{ok|warning|not-run|not-applicable}`] - Result of the Check

This is the result of the check. If this parameter is specified, only rows with this result will be displayed.

[-additional-info `<text>`] - Additional Information/Recovery Steps

This is additional information about the check. This field has more information and recovery steps for the warning. If this parameter is specified, only rows with this additional info will be displayed.

### Examples

The following example shows the execution of the command in a MetroCluster configuration with two nodes per cluster:

**metrocluster check volume commands**

Display check results for Volumes

**metrocluster check volume show**

Show results of the MetroCluster check for volumes

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**
The `metrocluster check volume show` command displays the results of volume checks performed by the `metrocluster check run` command.

The command displays the results of the following volume configuration checks:

- **unmirrored-flexgroups:** This check looks for flexgroups residing on unmirrored aggregates.
- **mixed-flexgroups:** This check looks for flexgroups residing on a mix of mirrored and unmirrored aggregates.

Additional information about the warnings, if any, and recovery steps can be viewed by running the command with the `-instance` parameter.

**Parameters**

`{ [-fields <fieldname>, ...] }`

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

`{ [-instance ]]}

If you specify the `-instance` parameter, the command displays detailed information about all fields.

`[-vserver <vserver name>] - Vserver Name`

This is the name of the vserver that contains the volume that the check results apply to. If this parameter is specified, only rows matching the specified cluster will be displayed.

`[-volume <volume name>] - Volume Name`

This is the name of the volume that the check results apply to. If this parameter is specified, only rows matching the specified volume will be displayed.

`[-check <MetroCluster Volume Check>] - Type of Check`

This is the type of the check performed. If this parameter is specified, only rows with this check will be displayed.

`[-result {ok|warning|not-run|not-applicable}] - Result of the Check`

This is the result of the check. If this parameter is specified, only rows with this result will be displayed.

`[-additional-info <text>, ...] - Additional Information/Recovery Steps`

This is additional information about the check. This field has more information and recovery steps for the warning. If this parameter is specified, only rows with this additional info will be displayed.

**Examples**
The following example shows the execution of the command in a MetroCluster configuration:

```
clusA::*> metrocluster check volume show

metrocluster config-replication commands
  Display configuration replication information

metrocluster config-replication cluster-storage-configuration commands
  Display configuration replication storage configuration

metrocluster config-replication cluster-storage-configuration modify
  Modify MetroCluster storage configuration information

  Availability: This command is available to cluster administrators at the advanced privilege level.

  Description
  The metrocluster config-replication cluster-storage-configuration modify command modifies the
  configuration of storage used for configuration replication.

  Parameters
  [-disallowed-aggregates <aggregate name>,...] - Disallowed Aggregates
    Use this parameter to set the list of storage aggregates that are not available to host storage for configuration replication.

  Examples
  The following example disallows two aggregates named aggr1 and aggr2:
Related references

metrocluster config-replication cluster-storage-configuration show on page 264

metrocluster config-replication cluster-storage-configuration show
Display MetroCluster storage configuration information

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
The metrocluster config-replication cluster-storage-configuration show command shows details of the configuration of the storage used for configuration replication.

The information displayed is the following:
• Disallowed Aggregates - The list of storage aggregates that are configured as not allowed to host storage areas.
• Auto-Repair - Displays true if the automatic repair of storage areas used by configuration replication is enabled.
• Auto-Recreate - Displays true if the automatic recreation of storage volumes used by configuration replication is enabled.
• Use Mirrored Aggregate - Displays true if storage areas for configuration replication are to be hosted on a mirrored aggregate.

Examples
The following is an example of the metrocluster config-replication cluster-storage-configuration show command:

cluster1:*> metrocluster config-replication cluster-storage-configuration show
Disallowed Aggregates: -
  Auto-Repair: true
  Auto-Recreate: true
Use Mirrored Aggregate: true

metrocluster config-replication resync-status commands
Display MetroCluster configuration synchronization status

metrocluster config-replication resync-status show
Display MetroCluster Configuration Resynchronization Status

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
The metrocluster config-replication resync-status show command displays the state of the configuration synchronization operation between the two clusters in the MetroCluster configuration.
This command displays the following details about the local cluster and the peer cluster:

- **Source**: This is the source side whose configuration is being replicated to the destination side.
- **Destination**: This is the destination side where the configuration is being replicated to from the source side.
- **State**: This is the state of the synchronization operation.
- **% Complete**: This is completion percentage of the operation.

### Examples

The following example shows the output of the command when synchronization is in progress:

```
clusterA::> metrocluster config-replication resync-status show

Source                  Destination             State       % Complete
----------------------- ----------------------- ----------- ----------
clusterA                clusterB                complete    -
clusterB                clusterA                complete    -
```

The following example shows the output of the command when synchronization from clusB to clusA is in progress:

```
clusA::> metrocluster config-replication resync-status show

Source                  Destination             State       % Complete
----------------------- ----------------------- ----------- ----------
clusterA                clusterB                complete    -
clusterB                clusterA                messaging   95
```

### metrocluster configuration-settings commands

Configuration settings to set up MetroCluster

### metrocluster configuration-settings show-status

Display the configuration settings status for a MetroCluster setup

**Availability**: This command is available to cluster administrators at the `admin` privilege level.

**Description**

The `metrocluster configuration-settings show-status` command displays the configuration settings status for nodes in a MetroCluster setup. If a DR group has not been created, then status for nodes in the local cluster only are displayed.

**Parameters**

```
[-fields <fieldname>, ...]
```

If you specify the `-fields <fieldname>, ...` parameter, the command displays only the fields that you specify.

```
[-instance ]
```

If this parameter is specified, the command displays detailed information about all entries.
[-cluster-uuid <UUID>] - Cluster UUID
If this parameter is specified, the command displays detailed information about all nodes in the cluster matching the specified cluster-uuid.

[-cluster <Cluster name>] - Cluster Name
If this parameter is specified, the command displays detailed information about all the nodes in the specified cluster.

[-node <text>] - Node Name
If this parameter is specified, the command displays information for the matching nodes.

[-configuration-status <text>] - Configuration Settings Status
If this parameter is specified, the command displays detailed information about all nodes with the specified configuration status.

[-config-error-info <text>] - Configuration Error Information
If this parameter is specified, the command displays detailed information about all nodes with the specified configuration error information.

Examples
The following example shows the display of MetroCluster setup status:

Nodes do not have a valid platform-specific personality value (equivalent to HAOSC parameter on non-Apollo platforms) for a MetroCluster setup.

clusA::> metrocluster configuration-settings show-status
Cluster          Node               Configuration Settings Status
----------------- -------- --------------------------------
clusA             A1                 not a MetroCluster setup
A2                 not a MetroCluster setup
2 entries were displayed.

MetroCluster setup uses FC links rather than IP link:

clusA::> metrocluster configuration-settings show-status
Cluster          Node               Configuration Settings Status
----------------- -------- --------------------------------
clusA             A1                 not applicable for FC and SAS
A2                 not applicable for FC and SAS
2 entries were displayed.

Output of the command when MetroCluster setup uses IP links and before "metrocluster configuration-settings dr-group create" command is run:

clusA::> metrocluster configuration-settings show-status
Cluster          Node               Configuration Settings Status
----------------- -------- --------------------------------
clusA             A1                 ready for DR group create
A2                 ready for DR group create
2 entries were displayed.

Output of the command after "metrocluster configuration-settings dr-group create" command is run:

clusA::> metrocluster configuration-settings show-status
Cluster          Node               Configuration Settings Status
----------------- -------- --------------------------------
clusA             A1
A2
266

Commands: Manual Page Reference
clusA
  A1  ready for interface create
  A2  ready for interface create
clusB
  B1  ready for interface create
  B2  ready for interface create
4 entries were displayed.

Output of the command after "metrocluster configuration-settings interface create" command is run for every node:

clusA::> metrocluster configuration-settings show-status
Cluster Node Configuration Settings Status
-------------------------- ------------------ ---------------------------------
clusA A1  ready for next interface create
        A2  ready for connection connect
clusB B1  ready for connection connect
        B2  ready for connection connect
4 entries were displayed.

Output of the command after "metrocluster configuration-settings connection connect" command is run:

usA::> metrocluster configuration-settings show-status
Cluster Node Configuration Settings Status
-------------------------- ------------------ ---------------------------------
clusA A1  completed
        A2  completed
clusB B1  completed
        B2  completed
4 entries were displayed.

Output of the command after "metrocluster configuration-settings connection connect" command is run and there are connection errors:

clusA::> metrocluster configuration-settings show-status
Cluster Node Configuration Settings Status
-------------------------- ------------------ --------------------------------
clusA A1  connection error
        A2  completed
clusB B1  connection error
        B2  completed
4 entries were displayed.

**metrocluster configuration-settings connection commands**

Configure connections between partner nodes

**metrocluster configuration-settings connection check**

Check the network connections between partner nodes

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.
Description
The `metrocluster configuration-settings connection check` command checks the settings of a MetroCluster over IP configuration.

This command is used for MetroCluster configurations that are connected through IP links.

Examples
The following example shows the output for the check command in MetroCluster over IP configurations:

```
clusA:*> metrocluster configuration-settings connection check
[Job 68] Job succeeded: Connect is successful.
Begin connection check.
Start checking the partner cluster.
Check partner cluster: PASS.
Start checking the configuration settings.
  Check configuration settings: PASS.
Start pinging the network endpoints from cluster "clusA".
  Ping network endpoints: PASS.
Start pinging the network endpoints from cluster "clusB".
  Ping network endpoints: PASS.
Start checking the network MTU sizes from cluster "clusA".
  Check network MTU sizes: PASS.
Start checking the network MTU sizes from cluster "clusB".
  Check network MTU sizes: PASS.
Start checking the network subnets from cluster "clusA".
  Check network subnets: PASS.
Start checking the network subnets from cluster "clusB".
  Check network subnets: PASS.
Start checking the storage daemons on cluster "clusA".
  Check storage daemons: PASS.
Start checking the storage daemons on cluster "clusB".
  Check storage daemons: PASS.
End of connection check.
```

`metrocluster configuration-settings connection connect`
Configure the network connections between partner nodes

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

Description
The `metrocluster configuration-settings connection connect` command configures the connections that mirror NV logs and access remote storage between partner nodes in a MetroCluster setup.

This command is used for MetroCluster setups that are connected through IP links. MetroCluster setups that are connected through FC links will configure the FC connections automatically.

The `metrocluster configuration-settings` commands are run in the following order to set up MetroCluster:

- `metrocluster configuration-settings dr-group create`,
- `metrocluster configuration-settings interface create`,
- `metrocluster configuration-settings connection connect`.

Before this command is run

- The DR groups must have been configured. Run the `metrocluster configuration-settings dr-group show` command to verify that every node is partnered in a DR group.
The network logical interfaces must have been configured on every node. Use the `metrocluster configuration-settings interface show` command to verify that every node has network logical interfaces configured to mirror NV logs and access remote storage.

After this command completes successfully, every node will:

- Have NV log mirroring configured and mirroring disabled. NV log mirroring will be enabled by the `metrocluster configure` command.
- Have access to remote storage. Use the `storage disk show -pool Pool1` command to view the remote disks that are hosted on DR partner nodes.

The DR groups and network logical interfaces that were configured by the `metrocluster configuration-settings` commands cannot be deleted after the connections have been configured. The `metrocluster configuration-settings connection disconnect` command must be run to remove the connections before the DR groups and network logical interfaces can be deleted.

### Examples

The following example shows configuration of connections in a MetroCluster over IP setup:

```plaintext
clusA::> metrocluster configuration-settings connection connect
[Job 269] Job succeeded: Connect is successful.

clusA::> metrocluster configuration-settings connection show

**metrocluster configuration-settings connection disconnect**

Tear down the network connections between partner nodes

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**

The `metrocluster configuration-settings connection disconnect` command removes the connections between nodes in a DR group that are used to mirror NV logs and access remote storage.

This command cannot be run if a node in the DR group has remote disks assigned to the node. The assigned ownership of remote disks can be removed by running the `storage disk removeowner` command.

The `metrocluster configuration-settings` commands are run in the following order to remove MetroCluster over IP configuration:

- metrocluster configuration-settings connection disconnect,
- metrocluster configuration-settings interface delete,
- metrocluster configuration-settings dr-group delete.

**Parameters**

- `-dr-group-id <integer>` - DR Group ID
  
  This parameter identifies the DR group to be disconnected.
Examples

The following example illustrates removal of connections in a four-node MetroCluster setup:

```
clusA::> metrocluster configuration-settings connection disconnect -dr-group-id 1
[Job 270] Job succeeded: Disconnect is successful.

clusA::> metrocluster configuration-settings show-status
Cluster           Node               Configuration Settings Status

metrocluster configuration-settings connection show
Display the connections between partner nodes in a MetroCluster setup

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The metrocluster configuration-settings connection show command displays the connection configuration information between the nodes in a MetroCluster setup.

Parameters
- [-fields <fieldname>,...]
  If you specify the -fields <fieldname>,... parameter, the command displays only the fields that you specify.
- [-instance ]
  If this parameter is specified, the command displays detailed information about all entries.
- [-dr-group-id <integer>] - DR Group ID
  If this parameter is specified, the command displays information for the matching DR group.
- [-cluster-uuid <UUID>] - Cluster UUID
  If this parameter is specified, the command displays information for the matching cluster specified by uuid.
- [-cluster <Cluster name>] - Cluster Name
  If this parameter is specified, the command displays information for the matching cluster.
- [-node-uuid <UUID>] - Node UUID
  If this parameter is specified, the command displays information for the matching node specified by uuid.
- [-node <text>] - Node Name
  If this parameter is specified, the command displays information for the matching nodes.
- [-home-port {<netport>|<ifgrp>}] - Home Port
  If this parameter is specified, the command displays information for the matching home-port.
- [-relationship-type <Roles of MetroCluster Nodes>] - Relationship Role Type
  If this parameter is specified, the command displays information for the matching relationship-type.
- [-source-address <IP Address>] - Source Network Address
  If this parameter is specified, the command displays information for the matching source address.
- [-destination-address <IP Address>] - Destination Network Address
  If this parameter is specified, the command displays information for the matching destination address.

[\text{-partner-cluster-uuid <UUID>}] - Partner Cluster UUID

If this parameter is specified, the command displays information for the matching partner-cluster-uuid.

[\text{-partner-node-uuid <UUID>}] - Partner Node UUID

If this parameter is specified, the command displays information for the matching partner-node-uuid.

[\text{-partner-node <text>}] - Partner Node Name

If this parameter is specified, the command displays information for the matching partner-node.

[\text{-partner-type <text>}] - Partner Relationship Type

If this parameter is specified, the command displays information for the matching partner-type.

[\text{-config-state <text>}] - Configuration State

If this parameter is specified, the command displays information for the matching config-state.

[\text{-config-error-info <text>}] - Configuration Error Information

If this parameter is specified, the command displays information for the matching config-error-info.

`metrocluster configuration-settings connection connect` on page 268

**metrocluster configuration-settings dr-group commands**

Configure DR groups

**metrocluster configuration-settings dr-group create**

Create a DR group in a MetroCluster setup

**Availability:** This command is available to cluster administrators at the `admin` privilege level.

**Description**

The `metrocluster configuration-settings dr-group create` command partners the nodes that will comprise a DR group in a MetroCluster setup.

This command is used for MetroCluster setups that are connected through IP links. MetroCluster setups that are connected through FC links will configure DR groups automatically and do not require the `metrocluster configuration-settings` commands.

The `metrocluster configuration-settings` commands are run in the following order to set up MetroCluster:

- `metrocluster configuration-settings dr-group create`,
- `metrocluster configuration-settings interface create`,
- `metrocluster configuration-settings connection connect`.

Before running this command, cluster peering must be configured between the local and partner clusters. Run the `cluster peer show` command to verify that peering is available between the local and partner clusters. This command configures a local node and a remote node as DR partner nodes. The command also configures the HA partner of the local node and the HA partner of the remote node as the other DR partner nodes in the DR group.

**Parameters**

- `partner-cluster <Cluster name>` - Partner Cluster Name
  
  Use this parameter to specify the name of the partner cluster.

- `local-node <nodename>|local` - Local Node Name
  
  Use this parameter to specify the name of a node in the local cluster.

- `remote-node <text>` - Remote Node Name
  
  Use this parameter to specify the name of a node in the partner cluster that is to be the DR partner of the specified local node.

**Examples**

The following example shows the creation of the MetroCluster DR group:
clusA::> metrocluster configuration-settings dr-group create -partner-cluster clusB -local-node A1 -remote-node B1
[Job 268] Job succeeded: DR Group Create is successful.
clusA::> metrocluster configuration-settings dr-group show

**metrocluster configuration-settings dr-group delete**

Delete a DR group in a MetroCluster setup

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**

The *metrocluster configuration-settings dr-group delete* command deletes a DR group and its node partnerships that were configured using the *metrocluster configuration-settings dr-group create* command.

This command cannot be run if the *metrocluster configuration-settings interface create* command has configured a network logical interface on a network port provisioned for MetroCluster. The *metrocluster configuration-settings interface delete* command must then be run to delete the network logical interfaces on every node in the DR group.

The *metrocluster configuration-settings* commands are run in the following order to remove the MetroCluster over IP configuration:

- *metrocluster configuration-settings connection disconnect*,
- *metrocluster configuration-settings interface delete*,
- *metrocluster configuration-settings dr-group delete*. 
Parameters

-dr-group-id <integer> - Dr group Id

This parameter identifies the DR group to be deleted.

Examples

The following example shows the deletion of the MetroCluster DR group:

```bash
clusA::> metrocluster configuration-settings dr-group delete -dr-group-id 1
Warning: This command deletes the existing DR group relationship. Are you sure you want to proceed ? [y|n]: y
[Job 279] Job succeeded: DR Group Delete is successful.
clusA::> metrocluster configuration-settings dr-group show
No DR groups exist.
clusA::> metrocluster configuration-settings show-status
  Cluster                  Node               Configuration Settings Status
  ------------------------ ------------------ ---------------------------------
  clusA                   A1                 ready for DR group create
                          A2                 ready for DR group create
  clusB                   B1                 ready for DR group create
                          B2                 ready for DR group create
4 entries were displayed.
```

`metrocluster configuration-settings dr-group show`

Display the DR groups in a MetroCluster setup

**Availability:** This command is available to cluster administrators at the `admin` privilege level.

**Description**

The `metrocluster configuration-settings dr-group show` command displays the DR groups and their nodes.

**Parameters**

```bash
{ [-fields <fieldname>,...]
    If you specify the -fields <fieldname>,... parameter, the command displays only the fields that you specify.
  | [-instance ]
    If this parameter is specified, the command displays detailed information about all entries.
  [-dr-group-id <integer>] - DR Group ID
    If this parameter is specified, the command displays information for the matching DR group.
  [-cluster-uuid <UUID>] - Cluster UUID
    If this parameter is specified, the command displays information for the matching cluster uuid.
```
[-cluster <Cluster name>] - Cluster Name
If this parameter is specified, the command displays information for the specified cluster.

[-node-uuid <UUID>] - Node UUID
If this parameter is specified, the command displays information for the matching nodes uuid.

[-node <text>] - Node Name
If this parameter is specified, the command displays information for the matching nodes.

[-dr-partner-node-uuid <UUID>] - DR Partner Node UUID
If this parameter is specified, the command displays information for the matching DR partner node uuid.

[-dr-partner-node <text>] - DR Partner Node Name
If this parameter is specified, the command displays information for the matching DR partner nodes.

Examples
The following example illustrates the display of DR group configuration in a four-node MetroCluster setup:

```
clusA::>  metrocluster configuration-settings dr-group show
  DR Group ID  Cluster Name       Node Name  DR Partner Node Name
  ----------  ---------------  -------  -------------------
    1         clusA            A1       B1
                A2       B2
        clusB            B2       A2
                B1       A1
  4 entries were displayed.
```

**metrocluster configuration-settings interface commands**

Configure network logical interfaces

**metrocluster configuration-settings interface create**

Create a MetroCluster interface

**Availability:** This command is available to **cluster** administrators at the **admin** privilege level.

**Description**
The **metrocluster configuration-settings interface create** command configures the network logical interfaces that will be used on a node in a MetroCluster setup to mirror NV logs and access remote storage.

This command is used for MetroCluster setups that are connected though IP links. MetroCluster setups that are connected through FC links do not require the user to provision network logical interfaces to mirror NV logs and access remote storage.

The **metrocluster configuration-settings** commands are run in the following order to set up MetroCluster:

- **metrocluster configuration-settings dr-group create**,  
- **metrocluster configuration-settings interface create**,  
- **metrocluster configuration-settings connection connect**.

Before running this command, the node's DR group must be configured using the **metrocluster configuration-settings dr-group create** command. Run the **metrocluster configuration-settings dr-group show** command to verify that the node's DR group has been configured.
Parameters

- **cluster-name <Cluster name>** - Cluster Name
  
  Use this parameter to specify the name of the local or partner cluster.

- **home-node <text>** - Home Node
  
  Use this parameter to specify the home node in the cluster which hosts the interface.

- **home-port {<netport>|<ifgrp>** - Home Port
  
  Use this parameter to specify the home port provisioned for MetroCluster.

- **address <IP Address>** - Network Address
  
  Use this parameter to specify the network address to be assigned to the home port.

- **netmask <Contiguous IP Mask>** - Netmask
  
  Use this parameter to specify the network mask to be assigned to the interface.

Examples

This example shows configuring logical interface on MetroCluster IP capable port:

```bash
clusA::> metrocluster configuration-settings interface create -cluster-name clusA -home-node A1 -home-port e0f -address 10.140.113.214 -netmask 255.255.192.0
[Job 281] Job succeeded: Interface Create is successful.
clusA::> metrocluster configuration-settings interface show
DR  Group  Cluster  Node | Network Address | Netmask | Gateway | State
----- ------ -------- ------- --------------- ---------- -----
1     clusA  A1       Home Port: e0f 10.140.113.214 255.255.192.0 - completed

Output after configuring all the interfaces:

clusA::> metrocluster configuration-settings interface show
DR  Group  Cluster  Node | Network Address | Netmask | Gateway | State
----- ------ -------- ------- --------------- ---------- -----
1     clusA  A1       Home Port: e0f 10.140.113.214 255.255.192.0 - completed
   Home Port: e0g 10.140.113.215 255.255.192.0 - completed
   A2
   Home Port: e0f 10.140.113.216 255.255.192.0 - completed
   Home Port: e0g 10.140.113.217 255.255.192.0 - completed
clusB  B2       Home Port: e0f 10.140.113.249 255.255.192.0 - completed
   Home Port: e0g 10.140.113.25 255.255.192.0 - completed
   B1
   Home Port: e0f 10.140.113.218 255.255.192.0 - completed
   Home Port: e0g 10.140.113.248 255.255.192.0 - completed
8 entries were displayed.
clusA::> metrocluster configuration-settings show-status
Cluster Node | Configuration Settings Status
------------- ---------------------------------
clusA A1     ready for connection connect
             A2     ready for connection connect
clusB B1     ready for connection connect
             B2     ready for connection connect

**MetroCluster Configuration-Settings Interface Delete**

Delete a MetroCluster interface

**Availability:** This command is available to cluster administrators at the admin privilege level.
**Description**

The `metrocluster configuration-settings interface delete` command deletes the network logical interface that was configured on a network port provisioned for MetroCluster.

This command cannot be run if the `metrocluster configuration-settings connection connect` command has set up the connections between the nodes in a DR group. The `metrocluster configuration-settings connection disconnect` command must then be run to remove the connections.

The `metrocluster configuration-settings` commands are run in the following order to remove the MetroCluster over IP configuration:

- `metrocluster configuration-settings connection disconnect`,
- `metrocluster configuration-settings interface delete`,
- `metrocluster configuration-settings dr-group delete`.

**Parameters**

`-cluster-name <Cluster name>` - Cluster Name

Use this parameter to specify the name of the local or partner cluster.

`-home-node <text>` - Home Node

Use this parameter to specify the home node in the cluster which hosts the interface.

`-home-port {<netport>|<ifgrp>>` - Home Port

Use this parameter to specify the home port provisioned for MetroCluster.

**Examples**

The following example shows the deletion of interface in a MetroCluster setup:

```
clusA::> metrocluster configuration-settings interface delete -cluster-name clusA -home-node A1 -home-port e0f
[Job 271] Job succeeded: Interface Delete is successful.
clusA::> metrocluster configuration-settings interface show
```

**metrocluster configuration-settings interface show**

Display the network logical interfaces provisioned for MetroCluster

**Availability:** This command is available to cluster administrators at the `admin` privilege level.

**Description**
The `metrocluster configuration-settings interface show` command displays the network logical interfaces that were provisioned for MetroCluster.

**Parameters**

```
[-fields <fieldname>,...]
  If you specify the `-fields <fieldname>,...` parameter, the command displays only the fields that you specify.

[-instance ]
  If this parameter is specified, the command displays detailed information about all entries.

[-dr-group-id <integer>] - DR Group ID
  If this parameter is specified, the command displays information for the matching DR group.

[-cluster-uuid <UUID>] - Cluster UUID
  If this parameter is specified, the command displays information for the matching cluster specified by uuid.

[-cluster <Cluster name>] - Cluster Name
  If this parameter is specified, the command displays information for the matching cluster.

[-node-uuid <UUID>] - Node UUID
  If this parameter is specified, the command displays information for the matching nodes uuid.

[-node <text>] - Node Name
  If this parameter is specified, the command displays information for the matching nodes.
```
[-home-port <netport>|<ifgrp>]] - Home Port
If this parameter is specified, all interfaces with home-port set to this value are displayed.

[-address <IP Address>]] - Network Address
If this parameter is specified, the command displays information for the matching network address.

[-netmask <Contiguous IP Mask>]] - Netmask
If this parameter is specified, all interfaces with netmask set to this value are displayed.

[-gateway <IP Address>]] - Gateway
If this parameter is specified, all interfaces with gateway set to this value are displayed.

[-config-state <text>]] - Configuration State
If this parameter is specified, all interfaces with this field set to the specified value are displayed.

[-config-error-info <text>]] - Configuration Error Information
If this parameter is specified, all interfaces with this field set to the specified value are displayed.

Examples
The following example illustrates display of logical interfaces configured in a four-node MetroCluster setup:

```
clusA::> metrocluster configuration-settings interface show
DR Group Cluster Node    Network Address Netmask         Gateway         State
----- ------- ------- --------------- --------------- --------------- ---------

B1
Home Port: e0f
10.140.113.218  255.255.192.0   -               completed
Home Port: e0g
10.140.113.248  255.255.192.0   -               completed
8 entries were displayed.
```

MetroCluster interconnect commands

MetroCluster interconnect commands

MetroCluster interconnect adapter commands

Manage MetroCluster interconnect adapters

MetroCluster interconnect adapter modify

Modify MetroCluster interconnect adapter settings

Availability: This command is available to cluster administrators at the advanced privilege level.
Description
The `metrocluster interconnect adapter modify` command enables you to modify settings of the MetroCluster interconnect adapter.

Parameters
- **-node `<nodename>|local`** - Node Name
  This parameter specifies the node name.
- **-is-ood-enabled `<true|false>`** - Is Out-Of-Order Delivery Enabled?
  This parameter specifies the out-of-order delivery setting on the adapter.

Examples
The following example enables out-of-order delivery for the port `fcvi_device_0` on the node `clusA-01`:

```
clusA::*> metrocluster interconnect adapter modify -node clusA-01 -adapter-port-name fcvi_device_0 -is-ood-enabled true
```

```text
Description
The `metrocluster interconnect adapter show` command displays interconnect adapter information for the nodes in a MetroCluster configuration.

This command displays the following details about the local node and the HA partner node:
- **Node**: This field specifies the name of the node in the cluster.
- **Adapter Name**: This field specifies the name of the interconnect adapter.
- **Adapter Type**: This field specifies the type of the interconnect adapter.
- **Link Status**: This field specifies the physical link status of the interconnect adapter.
- **Is OOD Enabled**: This field specifies the out-of-order delivery status of the interconnect adapter.
- **IP Address**: This field specifies the IP address assigned to the interconnect adapter.
- **Port Number**: This field specifies the port number of the interconnect adapter.

Parameters

- **[-fields `<fieldname>`, ...]**
  If you specify the `-fields `<fieldname>`, ...` parameter, the command output also includes the specified field or fields. You can use `-fields '?'` to display the fields to specify.

- **[-connectivity]**
  Displays the connectivity information from all the interconnect adapters to the connected nodes.

- **[-switch]**
  Displays details of switches connected to all the interconnect adapters.
[-connectivity-hidden ] (privilege: advanced)
  Displays additional connectivity information (IP address, Area ID, Port ID) from all the interconnect adapters
to the connected nodes.

[-instance ]
  If you specify the -instance parameter, the command displays detailed information about all fields.

[-node {<nodename> | local}] - Node Name
  Displays information only about the interconnect adapters that are hosted by the specified node.

[-adapter <text>] - Adapter
  Displays information only about the interconnect adapters that match the specified name.

[-port-name <text>] - Port Name
  Displays information only about the interconnect adapters that host the specified port name.

[-type <text>] - Adapter Type
  Displays information only about the interconnect adapters that match the specified adapter type.

[-physical-status <text>] - Physical Status
  Displays information only about the interconnect adapters that match the specified physical status.

[-wwn <text>] - Adapter Port World Wide Name
  Displays information only about the interconnect adapters that match the specified world wide name.

[-address <text>] - IP Address
  Displays information only about the interconnect adapters that match the specified IP address.

[-firmware-version <text>] - Firmware Version
  Displays information only about the interconnect adapters that match the specified firmware version.

[-link-speed <text>] - Link Speed
  Displays information only about the interconnect adapters that match the specified link speed.

[-link-speed-neg-type <text>] - Link Speed Negotiation Type
  Displays information only about the interconnect adapters that match the specified negotiated link speed type.

[-switch-name <text>] - Switch Name
  Displays information only about the interconnect adapters that are connected to the specified switch.

[-switch-model <text>] - Switch Model
  Displays information only about the interconnect adapters that are connected to the switch with the specified model.

[-switch-wwn <text>] - Switch WWName
  Displays information only about the interconnect adapters that are connected to the switch with the specified world wide name.

[-switch-vendor <text>] - Switch Vendor
  Displays information only about the interconnect adapters that are connected to the switch with the specified vendor.

[-switch-status <text>] - Switch Status
  Displays information only about the interconnect adapters that are connected to the switch with the specified operational status.

[-switch-port-number <text>] - Switch Port Number
  Displays information only about the interconnect adapters that are connected to the switch with the specified port number.
[-switch-port-wwpn <text>] - Switch Port WWPN
Displays information only about the interconnect adapters that are connected to the switch with the specified word wide port name.

[-remote-adapter-name-list <text>,...] - Remote Adapter Name List
Displays information only about the interconnect adapters that are connected to the specified remote adapters.

[-remote-adapter-wwn-list <text>,...] - Remote Adapter WWName List
Displays information only about the interconnect adapters that are connected to the remote adapters with the specified world wide names.

[-remote-adapter-address-list <text>,...] - Remote Adapter IP Address List
Displays information only about the interconnect adapters that are connected to the remote adapters with the specified IP addresses.

[-remote-adapter-port-id-list <Hex Integer>,...] - Remote Adapter Port ID List
Displays information only about the interconnect adapters that are connected to the remote adapters with the specified port IDs.

[-remote-adapter-domain-id-list <integer>,...] - Remote Adapter Domain ID List
Displays information only about the interconnect adapters that are connected to the remote adapters with the specified domain IDs.

[-remote-adapter-area-id-list <integer>,...] - Remote Adapter Area ID List
Displays information only about the interconnect adapters that are connected to the remote adapters with the specified Area IDs.

[-remote-partner-system-id-list <integer>,...] - Remote Partner System ID List
Displays information only about the interconnect adapters that are connected to the remote nodes with the specified System IDs.

[-remote-partner-name-list (<nodename>|local),...] - Remote Partner Name List
Displays information only about the interconnect adapters that are connected to the specified remote nodes.

[-is-ood-enabled (true|false)] - Is Out-of-Order Delivery Enabled?
Displays information only about the interconnect adapters that match the specified out-of-order delivery setting.

**Examples**

The following example shows the output of the command during normal operation (neither cluster is in switchover state):

```
clusA::> metrocluster interconnect adapter show

<table>
<thead>
<tr>

```
metrocluster interconnect mirror commands

Manage MetroCluster interconnect mirrors

metrocluster interconnect mirror show

Display MetroCluster interconnect mirror information

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The `metrocluster interconnect mirror show` command displays NVRAM mirror information for the nodes configured in a MetroCluster.

This command displays the following details about the local node and the HA partner node:

- Node: This field specifies the name of the node in the cluster.
- Partner Name: This field specifies the name of the partner node.
- Partner Type: This field specifies the type of the partner.
- Mirror Admin Status: This field specifies the administrative status of the NVRAM mirror between partner nodes.
- Mirror Oper Status: This field specifies the operational status of the NVRAM mirror between partner nodes.
- Adapter: This field specifies the name of the interconnect adapter used for NVRAM mirroring.
- Type: This field specifies the type of the interconnect adapter used for NVRAM mirroring.
- Status: This field specifies the physical status of the interconnect adapter used for NVRAM mirroring.

Parameters

```bash
[-fields <fieldname>, ...]
```

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

```bash
[[-instance]]
```

If you specify the `-instance` parameter, the command displays detailed information about all fields.

```bash
[-node <nodename> | local] - Node Name
```

If this parameter is specified, mirror details of the specified node are displayed.

```bash
[-partner-type {HA | DR | AUX}] - Partner Type
```

If this parameter is specified, mirror details of the specified partner type are displayed.

```bash
[-adapter <text>] - Adapter
```

If this parameter is specified, mirror details of the specified adapter are displayed.

```bash
[-type <text>] - Adapter Type
```

If this parameter is specified, mirror details of the specified adapter type are displayed.

```bash
[-status <text>] - Status
```

If this parameter is specified, mirror details of the adapter with the specified status are displayed.
Mirror Operational Status
If this parameter is specified, only mirror details with the specified operational status are displayed.

Partner Name
If this parameter is specified, mirror details of the specified partner are displayed.

Mirror Administrative Status
If this parameter is specified, only mirror details with the specified administrative status are displayed.

### Examples

metrocluster interconnect commands
**metrocluster interconnect mirror multipath commands**

Manage MetroCluster interconnect mirror multipath policy

**metrocluster interconnect mirror multipath show**

Display multipath information

*Availability:* This command is available to cluster administrators at the *admin* privilege level.

**Description**

The `metrocluster interconnect mirror multipath show` command displays the NVRAM mirror multipath policy for the nodes configured in a MetroCluster.

This command displays the following details about the local node and the HA partner node:

- **Node:** This field specifies the name of the node in the cluster.
- **Multipath Policy:** This field specifies the multipath policy used for NVRAM mirroring.

**Parameters**

```
[-fields <fieldname>, ...]
```

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `'-fields ?'` to display the fields to specify.

```
[-instance ]
```

If you specify the `-instance` parameter, the command displays detailed information about all fields.

```
[-node <nodename> | local] - Node Name
```

If this parameter is specified, mirror details of the specified node are displayed.

```
[-multipath-policy {no-mp|static-map|dynamic-map|round-robin}] - Multipath Policy
```

If this parameter is specified, nodes with the specified multipath policy are displayed.

**Examples**

The following example shows the output of the command:

```
clusA::> metrocluster interconnect mirror multipath show
Node           Multipath Policy
--------------- -----------------
clusA-1        static-map
clusA-2        static-map
```

**metrocluster node commands**

Display MetroCluster nodes
metrocluster node show

Display MetroCluster node configuration information

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The metrocluster node show command displays configuration information for the nodes in the MetroCluster configuration.

Parameters

{-fields <fieldname>, ...}  
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

[-partners]  
If this option is used the MetroCluster node partnership view will be displayed.

[-instance]  
If you specify the -instance parameter, the command displays detailed information about all fields.

[-dr-group-id <integer>] - DR Group ID  
If this parameter is specified, all nodes belonging to the specified DR group are displayed.

[-cluster <Cluster name>] - Cluster Name  
If this parameter is specified, all nodes belonging to the specified cluster are displayed.

[-node <Node name>] - Node Name  
If this parameter is specified, the specified node is displayed.

[-ha-partner <Node name>] - HA Partner Name  
If this parameter is specified, the node with the specified HA partner is displayed.

[-dr-cluster <Cluster name>] - DR Cluster Name  
If this parameter is specified, all nodes belonging to the specified cluster are displayed.

[-dr-partner <Node name>] - DR Partner Name  
If this parameter is specified, the node with the specified DR partner is displayed.

[-dr-auxiliary <Node name>] - DR Auxiliary Name  
If this parameter is specified, the node with the specified DR auxiliary partner is displayed.

[-node-uuid <UUID>] - Node UUID  
If this parameter is specified, the node with the specified UUID is displayed.

[-ha-partner-uuid <UUID>] - HA Partner UUID  
If this parameter is specified, the nodes with the specified HA partner is displayed.

[-dr-partner-uuid <UUID>] - DR Partner UUID  
If this parameter is specified, the node with the specified DR partner is displayed.

[-dr-auxiliary-uuid <UUID>] - DR Auxiliary UUID  
If this parameter is specified, the node with the specified DR auxiliary partner is displayed.

[-node-cluster-uuid <UUID>] - Node Cluster UUID  
If this parameter is specified, all nodes belonging to the specified cluster are displayed.

[-ha-partner-cluster-uuid <UUID>] - HA Partner Cluster UUID  
If this parameter is specified, all nodes whose HA partner belong to the specified cluster are displayed.
[\-dr-partner-cluster-uuid <UUID>] - DR Partner Cluster UUID  
If this parameter is specified, all nodes whose DR partner belong to the specified cluster are displayed.

[\-dr-auxiliary-cluster-uuid <UUID>] - DR Auxiliary Cluster UUID  
If this parameter is specified, all nodes whose DR auxiliary partner belong to the specified cluster are displayed.

[\-node-systemid <integer>] - Node System ID  
If this parameter is specified, all nodes with the specified system ID are displayed.

[\-ha-partner-systemid <integer>] - HA Partner System ID  
If this parameter is specified, all nodes with an HA partner with the specified system ID are displayed.

[\-dr-partner-systemid <integer>] - DR Partner System ID  
If this parameter is specified, all nodes with a DR partner with the specified system ID are displayed.

[\-dr-auxiliary-systemid <integer>] - DR Auxiliary System ID  
If this parameter is specified, all nodes with a DR auxiliary partner with the specified system ID are displayed.

[\-dr-mirroring-state <text>] - State of DR Mirroring Config  
If this parameter is specified, all nodes with this field set to the specified value are displayed. This field specifies if the NVRAM mirroring to the DR partner is enabled through the `metrocluster configure` command. This field needs to be set to "enabled" for the DR mirroring to be active.

[\-configuration-state <text>] - Configuration State of Node  
If this parameter is specified, all nodes with this field set to the specified value are displayed.

[\-additional-configuration-info <text>] - Additional Configuration Info  
If this parameter is specified, all nodes with this field set to the specified value are displayed.

[\-dr-operation-state <text>] - DR Operation State  
If this parameter is specified, all nodes with this field set to the specified value are displayed.

[\-dr-operation-time <integer>] - Time to Complete Operation (secs)  
If this parameter is specified, all nodes with this field set to the specified value are displayed.

[\-node-object-limit {on|off}] - Specifies if the Node Object Limits are Enforced  
If this parameter is specified, all nodes with this field set to the specified value are displayed.

[\-node-ha-partner <text>] - Node and its HA Partner  
If this parameter is specified, all nodes with this field set to the specified value are displayed.

[\-automatic-uso {true|false}] - Automatic USO (privilege: advanced)  
If this parameter is specified, all nodes with this field set to the specified value are displayed.

### Examples

The following example shows the output of the command before the MetroCluster configuration is done:

```
clusA::> metrocluster node show
DR    Group    Cluster    Node    Configuration DR State   Mirroring Mode
----- -------- --------- -------- --------------- -------- -------------------
    -    clusA     clusA-01    ready to configure
          clusA-02    ready to configure
          clusA-03    ready to configure
          clusA-04    ready to configure

4 entries were displayed.
```
The following example shows the output of the command when some DR groups in the MetroCluster configuration are not yet configured:

```
clusA::> metrocluster node show
DR Group Cluster Node  Configuration State Mirroring Mode
----- ------- ------------------ -------------- --------- --------------------
1     clusA   clusA-01           configured     enabled   normal
clusA-02           configured     enabled   normal
clusB   clusB-01           configured     enabled   normal
clusB-02           configured     enabled   normal
2     clusA   clusA-03           configured     enabled   normal
clusA-04           configured     enabled   normal
clusB   clusB-03           configured     enabled   normal
clusB-04           configured     enabled   normal
```

The following example shows the output of the command after all DR groups in the MetroCluster configuration are configured:

```
clusA::> metrocluster node show
DR Group Cluster Node  Configuration State Mirroring Mode
----- ------- ------------------ -------------- --------- --------------------
1     clusA   clusA-01           configured     enabled   normal
clusA-02           configured     enabled   normal
clusB   clusB-01           configured     enabled   normal
clusB-02           configured     enabled   normal
2     clusA   clusA-03           configured     enabled   normal
clusA-04           configured     enabled   normal
clusB   clusB-03           configured     enabled   normal
clusB-04           configured     enabled   normal
```

The following example shows the output of the command when some DR groups in the MetroCluster configuration are not yet configured:

```
clusA::> metrocluster node show
Node (HA Partner) DR Partner (DR Auxiliary)
---------------------------------------- ---------------------------------------
Cluster:                           clusA-
clusA-01 (-) - (-)
clusA-02 (-) - (-)
clusA-03 (-) - (-)
clusA-04 (-) - (-)
4 entries were displayed.
```

The following example shows the output of the command after all DR groups in the MetroCluster configuration are configured:

```
clusA::> metrocluster node show
Node (HA Partner) DR Partner (DR Auxiliary)
---------------------------------------- ---------------------------------------
Cluster:                           clusA-
clusA-03 (-) - (-)
clusA-04 (-) - (-)
Cluster:                           clusA clusB
clusA-01 (clusA-02) clusB-01 (clusB-02)
clusA-02 (clusA-01) clusB-02 (clusB-01)
6 entries were displayed.
```

The following example shows the output of the command when some DR groups in the MetroCluster configuration are not yet configured:

```
clusA::> metrocluster node show
Node (HA Partner) DR Partner (DR Auxiliary)
---------------------------------------- ---------------------------------------
Cluster:                           clusA-
clusA-03 (-) - (-)
clusA-04 (-) - (-)
Cluster:                           clusA clusB
clusA-01 (clusA-02) clusB-01 (clusB-02)
clusA-02 (clusA-01) clusB-02 (clusB-01)
Cluster:                           clusB-
clusB-01 (clusB-02) clusA-01 (clusA-02)
clusB-02 (clusB-01) clusA-02 (clusA-01)
6 entries were displayed.

**metrocluster operation commands**

Display MetroCluster operation status

**metrocluster operation show**

Display details of the last MetroCluster operation

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**

The `metrocluster operation show` command displays information about the most recent MetroCluster operation run on the local cluster.

This command will display information about all MetroCluster commands except for the commands in the `metrocluster check` directory. This command will not display any information after MetroCluster has been completely unconfigured using the `metrocluster unconfigure` command.

**Examples**

The following example shows the output of `metrocluster operation show` after running a `metrocluster configure` command was successful:

```
clusA::> metrocluster operation show
Operation: configure
    State: successful
    Start time: 2/15/2013 18:22:46
    End time: 2/15/2013 18:25:18
    Errors: -
```

**metrocluster operation history commands**

The history directory

**metrocluster operation history show**

Display details of all MetroCluster operations

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.
Description
The `metrocluster operation history show` command displays information about all the MetroCluster operations run on the local cluster.

This command will display information about all MetroCluster commands except for the commands in the `metrocluster check` directory. This command will not display any information after MetroCluster has been completely unconfigured using the `metrocluster unconfigure` command.

Parameters

```
([-fields <fieldname>, ...]

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

| [-instance ]

If you specify the `-instance` parameter, the command displays detailed information about all fields.

[-operation-uuid <UUID>] - Identifier for the Operation

This is the UUID of the operation. If this parameter is specified, only the operation with this UUID is displayed.

[-cluster <Cluster name>] - Cluster Where the Command Was Run

This is the name of the cluster where the command was run. If this parameter is specified, only the operations that were run in this cluster are displayed.

[-node-name <Node name>] - Node Where the Command Was run

This is the name of the node where the command was run. If this parameter is specified, only the operations that were run on this node are displayed.

[-operation <MetroCluster Operation Name>] - Name of the Operation

This is the name of the operation. If this parameter is specified, only the operations with this name are displayed.

[-start-time <MM/DD/YYYY HH:MM:SS>] - Start Time

This is the time the operation started execution. If this parameter is specified, only the operations that were started at this time are displayed.

[-state <MetroCluster Operation state>] - State of the Operation

This is the state of the operation. If this parameter is specified, only the operations that are in this state are displayed.

[-end-time <MM/DD/YYYY HH:MM:SS>] - End Time

This is the time the operation completed. If this parameter is specified, only the operations that completed at this time are displayed.

[-error-list <text>, ...] - Error List For the Operation

This is the list of errors that were encountered during an operation's execution. If this parameter is specified, only the operations that have the matching errors are displayed.

[-job-id <integer>] - Identifier for the Job

This is the job id for the operation. If this parameter is specified, only the operation that has the matching job id displayed.

[-additional-info <text>] - Additional Info for Auto Heal

This is the completion status of the auto heal aggregates and auto heal root aggregates phases when processing switchover with auto heal.

```
Examples
The following example shows the output of `metrocluster operation history show` after some MetroCluster operations have been performed:

```
clusA::> metrocluster operation history show
Operation        State          Start time       End time
---------------- -------------- ---------------- ------------------
configure        successful     2/15/2013 18:22:46

**metrocluster vserver commands**

Manage MetroCluster Vservers

**metrocluster vserver recover-from-partial-switchback**

Recover vservers from partial switchback

**Availability:** This command is available to `cluster` administrators at the `advanced` privilege level.

**Description**
The `metrocluster vserver recover-from-partial-switchback` command executes the necessary steps needed for a Vserver to be in healthy state after partial completion of the Switchback.

Examples

```
cluster::> metrocluster vserver recover-from-partial-switchback
```

Related references
- `metrocluster vserver recover-from-partial-switchover` on page 296

**metrocluster vserver recover-from-partial-switchover**

Recover vservers from partial switchover

**Availability:** This command is available to `cluster` administrators at the `advanced` privilege level.

**Description**
The `metrocluster vserver recover-from-partial-switchover` command executes the necessary steps needed for a Vserver to be in healthy state after partial completion of the Switchover.
Examples

```shell
cluster::> metrocluster vserver recover-from-partial-switchover
```

**metrocluster vserver resync**

Resynchronize Vserver with its partner Vserver

**Availability:** This command is available to cluster administrators at the *admin* privilege level.

**Description**
The `metrocluster vserver resync` command resynchronizes the Vserver with its partner Vserver

**Parameters**

- `-cluster <Cluster name>` - *Cluster Name*
  Name of the cluster where the Vserver belongs

- `-vserver <vserver>` - *Vserver*
  Name of the Vserver to be resynchronized

Examples

```shell
cluster::> metrocluster vserver resync -cluster clus1 -vserver vs1
```

Related references

* metrocluster vserver show on page 297

**metrocluster vserver show**

Display MetroCluster Vserver relationships

**Availability:** This command is available to cluster administrators at the *admin* privilege level.

**Description**
The `metrocluster vserver show` command displays configuration information for all pairs of Vservers in MetroCluster.

**Parameters**

```
{ [-fields <fieldname>,...]
  The command output includes the specified field or fields

  | [-creation-time] (privilege: advanced)
  Shows the last configuration modification time on the Vserver

  | [-instance ]
  If you specify the *instance* parameter, the command displays detailed information about all fields.
```

metrocluster vserver commands 297
[-cluster <Cluster name>] - Cluster Name
  Name of the cluster where the Vserver belongs

[-vserver <vserver>] - Vserver
  Name of the Vserver

[-partner-vserver <vserver>] - Partner Vserver
  Name of the partner Vserver

[-configuration-state (healthy|unhealthy|degraded|pending-setup|syncing|replication-paused|pending-switchback)] - Configuration State
  Configuration states include:
  • healthy
  • unhealthy
  • degraded indicates that Vservers are not in sync
  • syncing indicates that the Vserver configuration is being synchronized
  • replication-paused indicates that the configuration replication was manually paused
  • pending-setup indicates that partner Vserver creation is pending

[-corrective-action <text>] - Corrective Action
  Corrective action which can be followed to successfully create the partner Vserver

  Last configuration modification time on the Vserver

[-out-of-sync [true]] - Is out of sync
  Indicates that the Vserver configuration replication is not in sync

[-config-resume-time <MM/DD/YYYY HH:MM:SS>] - Configuration Resume Time
  Displays the resume time of the Vserver configuration replication

Examples
The following example shows the output of the command when partner Vservers are created

clusA::> metrocluster vserver show
Cluster: clusA
  Vserver                  Partner  Configuration
  -----------------------  -------------  -----------------
  clusA                    clusB              healthy
  vs1                      vs1-mc         healthy

Cluster: clusB
  Vserver                  Partner  Configuration
  -----------------------  -------------  -----------------
  clusB                    clusA              healthy

3 entries were displayed.

The following example shows the output of the command when the partner Vserver creation is pending

clusA::> metrocluster vserver show
Cluster: clusA
  Vserver                  Partner  Configuration
  -----------------------  -------------  -----------------
  clusB                    clusA              healthy

*metrocluster vserversync* on page 297

**Network Commands**

Manage physical and virtual network connections

The network commands enable you to manage the network interfaces in a cluster.

**network ping**

Ping

*Availability:* This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

*Description*

The network ping command displays whether a remote address is reachable and responsive, the (if specified) number of transmitted and received packets, and their round-trip time. The command requires a source node or logical interface from where the ping will be run, and a destination IP address. You can specify the source node by name, or a logical interface and its Vserver.

*Parameters*

```
{-node <nodename>} - Node

| -lif <lif-name>} - Logical Interface

{-vserver <vserver>} - Vserver

[-use-source-port {true|false}] - (DEPRECATED)-Use Source Port of Logical Interface (privilege: advanced)

This parameter is only applicable when the -lif parameter is specified. When set to true, the ping packet will be sent out via the port which is currently hosting the IP address of the logical interface. Otherwise, the ping packet will be sent out via a port based on the routing table.

*Note:* The use-source-port parameter is deprecated and may be removed in a future release of Data ONTAP.

-destination <Remote InetAddress> - Destination

Use this parameter to specify the remote internet address destination of the ping.

[-show-detail | -s {true}] - Show Detail Output

Use this parameter to display detailed output about the ping.
[-record-route | -R [true]] - Record Route
Use this parameter to display the route followed by the ping. You should set this option to false for pinging to succeed.

[-verbose | -v [true]] - Show All ICMP Packets
Use this parameter to display all ICMP packets.

[-packet-size <integer>] - Packet Size
Use this parameter to specify the number of data bytes to be sent in the ping packet. The default is 56 bytes, which is 64 ICMP data bytes total after 8 bytes of ICMP header data is added.

[-count <integer>] - Count
Use this parameter to specify the maximum number of ECHO_REQUESTS to be sent to the destination. The default is 20 requests. In the absence of the 'show-detail' option, ping reports that the destination is alive after receiving the first ECHO_REPLY response, independent of this value.

[-wait <integer>] - Packet Send Wait Time (secs)
Use this parameter to specify the number of seconds to wait between sending packets. The default is one second.

[-flood [true]] - Flood Ping (privilege: advanced)
Use this parameter to execute the command in flood mode. In flood mode, the command issues pings as fast as they are received, unless you specify a wait time.

[-disallow-fragmentation | -D [true]] - Disallow Packet Fragmentation
Use this parameter to prevent transport mechanisms from fragmenting ping packets in transit. Preventing fragmentation assures consistent packet size, making it easier to see transport bottlenecks.

[-wait-response <integer>] - Packet Response Wait Time (ms)
Use this parameter to specify the number of milliseconds to wait for each response packet. The default is 10000 milliseconds (10 seconds).

Examples
This example shows a ping from node xena to the destination server 10.98.16.164 with the server responding that it is up and running.

```
cluster1:/> network ping -node xena -destination 10.98.16.164
(network ping)
10.98.16.164 is alive
```

network ping6
Ping an IPv6 address

**Availability:** This command is available to cluster and Vserver administrators at the admin privilege level.

**Description**
The network ping6 command uses the ICMPv6 protocol's mandatory ICMP6_ECHO_REQUEST datagram to elicit an ICMP6_ECHO_REPLY from a host or gateway. ICMP6_ECHO_REQUEST datagrams ("pings") have an IPv6 header, and ICMPv6 header formatted as documented in RFC2463.

**Parameters**
{-node <nodename> - Node Name
Use this parameter to originate ping6 from the specified node.
-lif <lif-name> - Logical Interface
  Use this parameter to originate ping6 from the specified logical interface.

-vserver <vserver name> - Vserver Name
  Use this parameter to originate ping6 from the specified Vserver. The default value is the system Vserver for cluster administrators.

-destination <Remote InetAddress> - Destination
  Use this parameter to specify the IPv6 address of the destination node.

[-buffer-size | -b <integer>] - Socket Buffer Size
  Use this parameter to set the socket buffer size.

[-count | -<integer>] - Max Requests to Send/Receive
  Use this parameter to specify the maximum number of requests and replies. The default value is 20.

[-reverse-lookup | -H [true]] - Reverse-lookup of IPv6 addresses
  Use this parameter to specify reverse-lookup of IPv6 addresses. Unless this parameter is specified, ping6 command does not attempt reverse lookup.

[-interval | -i <integer>] - Wait between Packets (secs)
  Use this parameter to specify the delay time between packets in seconds. The default value is 1 second. This parameter is incompatible with the flood parameter.

[-preload | -l <integer>] - Send Packets as Fast as Possible (privilege: advanced)
  Use this parameter if preload is required. If specified, ping6 sends that many packets as fast as possible before falling into its normal mode of behaviour.

[-use-source-port (true|false)] - Use Source Port of Logical Interface (privilege: advanced)
  This parameter is only applicable when the -lif parameter is specified. When set to true, the ping packet will be sent out via the port which is currently hosting the IP address of the logical interface. Otherwise, the ping packet will be sent out via a port based on the routing table.

[-pattern | -p <text>] - Up to 16 'pad' Specified for Out Packet
  Use this parameter to fill the -16 'pad' bytes in the sent packet. This is useful for diagnosing data dependent problems in a network. For example, -pattern ff causes the sent packet to be filled with all ones.

[-packet-size <integer>] - Packet Size
  Use this parameter to specify the number of data bytes to be sent. The default is 56, which translates to 64 ICMP data bytes when combined with the 8 bytes of ICMP header data.

[-verbose | -v [true]] - Show All ICMP Packets
  Use this parameter to get verbose output. Verbose output displays both source address and destination addresses. Received ICMP packets other than ECHO_RESPONSE are listed. This parameter can be used only in conjunction with the show-detail parameter.

[-show-detail | -s [true]] - Show Detail Output
  Use this parameter to display detailed output about the ping.

[-flood | -f [true]] - Flood Ping (privilege: advanced)
  Use this parameter to output packets as fast as they come back or one hundred times per second, whichever is more. For every ECHO_REQUEST sent a period "." is printed, while for every ECHO_REPLY received a backspace is printed. This provides a rapid display of how many packets are being dropped. This can be very hard on a network and should be used with caution.

[-disable-fragmentation | -D [true]] - Disable Fragmentation.
  Use this parameter to disallow fragmentation of the outgoing packets, if they do not fit in the Maximum Transmission Unit.
Examples
This example shows a ping6 from node ‘node1’ to the destination server ipv6.google.com with the server responding that it is up and running.

```
cluster1:~> network ping6 -node node1 -destination ipv6.google.com
ipv6.google.com is alive.
```

**network test-path**

Test path performance between two nodes

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

**Description**
The `network test-path` command runs a performance test between two nodes. The command requires a source node, destination node, destination cluster, and application, or session type. All tests are run using intracluster or intercluster LIFs, depending on whether the test is between two nodes in the same cluster, or between nodes in peered clusters.

The test itself is different from most bandwidth test tools. It creates a "session" consisting of TCP connections between all possible paths between the nodes being tested. This is how internal Data ONTAP applications communicate between nodes. This means the test is using multiple paths, and thus the bandwidth reported might exceed the capacity of a single 10 Gb path.

**Parameters**

- `-source-node <nodename>|local` - Node Initiating Session
  
  Use this parameter to specify the node that initiates the test. Source-node parameter must be a member of the cluster in which the command is run.

- `-destination-cluster <Cluster name>` - Cluster Containing Passive Node
  
  Use this parameter to specify the destination cluster; the local cluster, or a peered cluster.

- `-destination-node <text>` - Remote Node in Destination Cluster
  
  Use this parameter to specify the destination node in the destination cluster.

- `-session-type {AsyncMirrorLocal|AsyncMirrorRemote|RemoteDataTransfer}` - Type of Session to Test
  
  The session type parameter is used to mimic the application settings used. A session consists of multiple TCP connections.
  
  - AsyncMirrorLocal: settings used by SnapMirror between nodes in the same cluster
  - AsyncMirrorRemote: settings used by SnapMirror between nodes in different clusters
  - RemoteDataTransfer: settings used by Data ONTAP for remote data access between nodes in the same cluster
  
  The default session-type is AsyncMirrorRemote.
Examples

The following example runs a test between two nodes in the same cluster:

```
cluster1::*> network test-path -source-node node1 -destination-cluster cluster1 -destination-node node2
```

Test Duration: 10.65 secs
Send Throughput: 1092.65 MB/sec
Receive Throughput: 1092.65 MB/sec
MB Sent: 11633.69
MB Received: 11633.69
Avg Latency: 64.40 ms
Min Latency: 2.41 ms
Max Latency: 2099.17 ms

network traceroute

Traceroute

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description

The network traceroute command performs a network probe from a node to a specified IP address. The command requires a source node or logical interface and a destination IP address. You can specify the source node by name, or specify a logical interface and its Vserver. The traceroute is performed between the source and destination.

Parameters

```
{-node <nodename> | -lif <lif-name>} - Node
Use this parameter to originate the traceroute from the node you specify.

|-lif <lif-name> | -lif - Logical Interface
Use this parameter to originate the traceroute from the specified network interface.

-vserver <vserver> - LIF Owner
Use this parameter to originate the traceroute from the Vserver where the intended logical interface resides.
The default value is the system Vserver for cluster administrators.

-destination <Remote InetAddress> - Destination
Use this parameter to specify the remote internet address destination of the traceroute.

[-maxttl | -m <integer>] - Maximum Number of Hops
Use this parameter to specify the maximum number of hops (time-to-live) setting used by outgoing probe packets. The default is 30 hops.

[-numeric | -n [true]] - Print Hop Numerically
Use this parameter to print the hop addresses only numerically rather than symbolically and numerically.

[-port <integer>] - Base UDP Port Number
Use this parameter to specify the base UDP port number used in probes. The default is port 33434.

[-packet-size <integer>] - Packet Size
Use this parameter to specify the size of probe packets, in bytes.
```
network traceroute6

traceroute6

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The network traceroute6 command performs a network probe from a node to a specified IPv6 address. The command requires a source node or logical interface, Vserver from where traceroute6 will originate and a destination IPv6 address. traceroute6 is performed between the source and destination.

Parameters
{-node <nodename> - Node
  Use this parameter to originate traceroute6 from the node you specify. This parameter is available only to cluster administrators.

| -lif <lif-name> | Logical Interface
  Use this parameter to originate traceroute6 from the logical interface you specify.

-vserver <vserver name> - LIF Owner
  Use this parameter to originate traceroute6 from the Vserver you specify. The default value is the system Vserver for cluster administrators.

[-debug-mode | -d [true]] - Debug Mode
  Use this parameter to enable socket level debugging. The default value is false.

{ [-icmp6 | -I [true]] - ICMP6 ECHO instead of UDP
  Use this parameter to specify the use of ICMP6 ECHO instead of UDP datagrams for the probes. The default value is false.

| [-udp | -U [true]] - UDP
  Use this parameter to specify the use of UDP datagrams for the probes. The default value is true.
-numeric| -n [true] - Print Hops Numerically
Use this parameter to print the hop addresses only numerically rather than symbolically and numerically. The default value is false.

-verbose| -v [true] - Verbose Output
Use this parameter to display all received ICMP packets, rather than just TIME_EXCEEDED and UNREACHABLE packets. The default value is false.

-first-hop| -f <integer> - Number of Hops to Skip in Trace
Use this parameter to specify the number of hops to skip in trace. The default value is 1.

-gateway| -g <Remote InetAddress> - Intermediate Gateway
Use this parameter to specify the intermediate gateway.

-hop-limit| -m <integer> - Maximum Number of Hops
Use this parameter to specify the maximum hoplimit, upto 255. The default value is 64 hops.

-port| -p <integer> - Base UDP Port Number
Use this parameter to specify the base UDP port number used in probes. The default value is port 33434.

-nqueries| -q <integer> - Number of Queries
Use this parameter to specify the number of probes per hop. The default value is 3 probes.

-wait-time| -w <integer> - Wait Between Packets (secs)
Use this parameter to specify the delay time between probes in seconds. The default value is 5 seconds.

-destination <Remote InetAddress> - Destination
Use this parameter to specify the remote IPv6 address destination of traceroute6.

-packet-size <integer> - Packet Size
Use this parameter to specify the size of probe packets, in bytes. The default value is 16 bytes for ICMP6 ECHO and 12 bytes for UDP datagrams.

Examples
The following example shows traceroute6 from node node1 to the destination fd20:8b1e:b255:4071:d255:1fcd:a8cd:b9e8.

```
cluster1::> network traceroute6 -node node1 -vserver vs1
        -destination 3ffe:b00:c18:1::10
traceroute6 to 3ffe:b00:c18:1::10 (3ffe:b00:c18:1::10)
from 2001:0db8:0000:f101::2,
64 hops max, 12 byte packets
 1  2001:0db8:0000:f101::1 4.249 ms  2.021 ms  0.864 ms
 2  3ffe:2000:0:400:::1  0.831 ms  0.579 ms
 3  3ffe:2000:0:1::132  227.693 ms  227.596 ms  227.439 ms
 4  3ffe:00:8023:2b::2 227.028 ms  228.267 ms  231.891 ms
 5  3ffe:2e00:e:c::3  227.929 ms  228.696 ms  228.558 ms
 6  3ffe:b00:c18:1::10  227.702 ms  227.806 ms  227.439 ms
```

network arp commands
The arp directory
network arp create

Create static ARP entry

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The network arp create command creates a static ARP entry for a given Vserver. Specially created ARP entries will be stored permanently in the Vserver context and will be used by the network stack.

Parameters
-vserver <vserver name> - Vserver Name
Use this parameter to specify the name of the Vserver on which the ARP entry is created.

-remotehost <IP Address> - Remote IP Address
Use this parameter to specify the IP address to be added as an ARP entry.

-mac <MAC Address> - MAC Address
Use this parameter to specify the MAC address (Ethernet address) for the host specified with -remotehost. Specify the MAC address as six hex bytes separated by colons.

Examples
The following example creates a static ARP entry on Vserver vs1 for the remote host with the IP address 10.63.0.2 having MAC address 40:55:39:25:27:c1

    cluster1::> network arp create -vserver vs1 -remotehost 10.63.0.2 -mac 40:55:39:25:27:c1

network arp delete

Delete static ARP entry

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The network arp delete command deletes static ARP entries from the Vserver and from the network stack.

Parameters
-vserver <vserver name> - Vserver Name
Use this parameter to specify the name of the Vserver from which the ARP entry is deleted.

-remotehost <IP Address> - Remote IP Address
Use this parameter to specify the IP address of the ARP entry being deleted.

Examples
The following example deletes the ARP entry for IP address 10.63.0.2 from the Vserver vs1.

    cluster1::> network arp delete -vserver vs1 -remotehost 10.63.0.2
**network arp show**

Display static ARP entries

**Availability:** This command is available to cluster and Vserver administrators at the admin privilege level.

**Description**
The `network arp show` command displays static ARP entries present in a given Vserver. This command will not display dynamically learnt ARP entries in the network stack. Use the `network arp active-entry show` command to display dynamically learned ARP entries in the network stack.

**Parameters**

{ [-fields <fieldname>, ...]  
Use this parameter to display only certain fields of the ARP table.  
} [-instance ]  
Use this parameter to display all the fields of the ARP table.  
[-vserver <vserver name>] - Vserver Name  
Use this parameter to display ARP entries that are specific to a given Vserver.  
[-remotehost <IP Address>] - Remote IP Address  
Use this parameter to display ARP entries for the specified IP address  
[-mac <MAC Address>] - MAC Address  
Use this parameter to display ARP entry for the specified MAC address  
[-ipspace <IPspace>] - IPspace  
Use this parameter to specify the IPspace associated with the Vserver

**Examples**
The following example displays static ARP entries from the Vserver vs1.

```
cluster1::> network arp show -vserver vs1
Vserver    Remote Host       MAC Address
----------- ----------------- -----------------
vs1        10.238.0.2        40:55:39:25:27:c1
```

**Related references**

`network arp active-entry show` on page 308

**network arp active-entry commands**

Manage active ARP entries

**network arp active-entry delete**

Delete active ARP entry from a System or Admin Vserver

**Availability:** This command is available to cluster administrators at the advanced privilege level.
Description
The `network arp active-entry delete` command deletes dynamically learned ARP entries from the network stack of a node. To delete statically configured ARP entries use the `network arp delete` command.

Parameters
- `node `<nodename>` | local` - Node
  Use this parameter to specify the name of the node in which the ARP entry is deleted.
- `vserver `<vserver>` - System or Admin Vserver Name
  Use this parameter to specify the name of the Vserver in which the ARP entry is deleted. Only Vservers with a type of Admin or System have dynamically learned ARP entries.
- `subnet-group `<IP Address/Mask>` - Subnet Group Name
  Use this parameter to specify the name of the routing group in which the ARP entry is deleted.
- `remotehost `<text>` - Remote IP Address
  Use this parameter to specify the IP address to be deleted from the active ARP entries.
- `port `<text>` - Port
  Use this parameter to specify the name of the Port to be deleted from the active ARP entries.

Examples
The following example deletes the active ARP entry with an IP address of 10.224.64.1, subnet group of 0.0.0.0/0, port e0c on node node2 in the Admin Vserver cluster1:

```
cluster1::network arp active-entry*> delete -node cluster1-01 -vserver cluster1 -subnet-group 0.0.0.0/0 -remotehost 10.224.64.1 -port e0c
```

Related references
- `network arp delete` on page 306

`network arp active-entry show`
Display active ARP entries organized by Vserver

Availability: This command is available to cluster administrators at the `advanced` privilege level.

Description
The `network arp active-entry show` command displays ARP entries present in the network stack of the node. The entries includes both dynamically learned ARP entries and user configured static ARP entries.

Parameters

- `[[-fields `<fieldname>`,...]` Use this parameter to display only certain fields of the active ARP table.
- `[-instance ]]` Use this parameter to display all the fields of the active ARP table.
- `[-node `<nodename>` | local]` - Node
  Use this parameter to display active ARP entries that are specific to a given node.
- `[-vserver `<vserver>`]` - System or Admin Vserver Name
  Use this parameter to display active ARP entries that are specific to a given System or Admin Vserver. Data and Node Vservers will not have any active-arp entries.
[-subnet-group <IP Address/Mask>] - Subnet Group Name
Use this parameter to display active ARP entries that are specific to a given subnet group.

[-remotehost <text>] - Remote IP Address
Use this parameter to display active ARP entries for the specified IP address.

[-port <text>] - Port
Use this parameter to display active ARP entries for the specified Port name.

[-mac <text>] - MAC Address
Use this parameter to display the active ARP entry for the specified MAC address.

[-ipspace <IPspace>] - IPspace
Use this parameter to specify the IPspace associated with the System or Admin Vserver.

**Examples**
The following example displays active ARP entries for the Admin Vserver cluster1:

```
cluster1::*> network arp active-entry show -vserver cluster1
Node: node-01
Vserver: cluster1
Subnet Group: 169.254.0.0/16
Remote IP Address  MAC Address    Port
-----------------  ----------------- -------
169.254.106.95    0:55:39:27:d1:c1  lo
```

**network bgp commands**
The bgp directory

**network bgp config commands**
Manage BGP configuration

**network bgp config create**
Create BGP configuration

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

**Description**
The `network bgp config create` command is used to create the border gateway protocol (BGP) configuration for a node. It can be used to override the BGP parameters defined in the global BGP defaults.

**Parameters**

- **-node (<nodename>|local)** - Node
  This parameter specifies the node on which configuration details will be created.

- **-asn <integer>** - Autonomous System Number
  This parameter specifies the autonomous system number (ASN). The ASN attribute is a non-negative 16-bit integer. It should typically be chosen from RFC6996 "Autonomous System (AS) Reservation for Private Use" or the AS number assigned to the operator's organization.
-hold-time <integer> - Hold Time
This parameter specifies the hold time in seconds. The default value is 180.

-router-id <IP Address> - Router ID
This parameter specifies the local router ID. The router-id value takes the form of an IPv4 address. The default router-id will be initialized using a local IPv4 address in admin vserv.

Examples

```
cluster1::> network bgp config create -node node1 -asn 10 -hold-time 180 -router-id 10.0.1.112
```

network bgp config delete
Delete BGP configuration

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
The network bgp config delete command deletes a node's border gateway protocol (BGP) configuration. A BGP configuration cannot be deleted if there are BGP peer groups configured on the associated node.

Parameters

-node <nodename>|local - Node
This parameter specifies the node for which the BGP configuration will be deleted.

Examples

```
cluster1::> network bgp config delete -node node1
```

network bgp config modify
Modify BGP configuration

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
The network bgp config modify command is used to modify a node's border gateway protocol (BGP) configuration.

Parameters

-node <nodename>|local - Node
This parameter specifies the node on which BGP configuration will be modified.

[ -asn <integer> ] - Autonomous System Number
This parameter specifies the autonomous system number (ASN). The ASN attribute is a non-negative 16-bit integer. It should typically be chosen from RFC6996 "Autonomous System (AS) Reservation for Private Use" or the AS number assigned to the operator's organization.

[ -hold-time <integer> ] - Hold Time
This parameter specifies the hold time in seconds.
[-router-id <IP Address>] - Router ID

This parameter specifies the local router ID. The router-id value takes the form of an IPv4 address.

Examples

```
cluster1::> network bgp config modify -node node1 -router-id 1.1.1.1 -asn 20
```

network bgp config show

Display BGP configuration

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The network bgp config show command displays the border gateway protocol (BGP) configuration for each node.

Parameters

{ [-fields <fieldname>, ...]  
  If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use -fields ? to display the fields to specify. 
  | [-instance ]  
  If you specify the -instance parameter, the command displays detailed information about all fields. 
  [-node (<nodename>|local)] - Node  
  This parameter selects the BGP configurations that match the specified node. 
  [-asn <integer>] - Autonomous System Number  
  This parameter selects the BGP configurations that match the specified autonomous system number. 
  [-hold-time <integer>] - Hold Time  
  This parameter selects BGP configurations that match the specified hold time. 
  [-router-id <IP Address>] - Router ID  
  This parameter selects the BGP configurations that match the specified router ID. 

Examples

```
cluster1::> network bgp config show
       Autonomous
       System          Hold Time          Router ID
       Node  Number   (seconds)         ---------
node1  10     180        10.0.1.112
```

network bgp defaults commands

Manage default BGP configuration
network bgp defaults modify

Modify BGP defaults

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
The network bgp defaults modify command modifies the global defaults for border gateway protocol (BGP) configurations.

Parameters

[-asn <integer>] - Autonomous System Number
This parameter specifies the autonomous system number (ASN). The ASN attribute is a non-negative 16-bit integer. It should typically be chosen from RFC6996 "Autonomous System (AS) Reservation for Private Use", or the AS number assigned to the operator's organization. The default ASN is 65501.

[-hold-time <integer>] - Hold Time
This parameter specifies the hold time in seconds. The default value is 180.

Examples

```
cluster1::> network bgp defaults modify -asn 20
```

network bgp defaults show

Display BGP defaults

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The network bgp defaults show command displays the global defaults for border gateway protocol (BGP) configurations.

Examples

```
cluster1::> network bgp defaults show
Autonomous
System Number Hold Time
(Seconds)
------------------
10 180
```

network bgp vserver-status commands

Display vserver BGP status

network bgp vserver-status show

Display Vserver BGP status

Availability: This command is available to cluster administrators at the admin privilege level.
Description
The network bgp vserver-status show command displays the per-node border gateway protocol (BGP) status for each vserver. The BGP status for a particular vserver is "up" when at least one BGP peer group supporting that vserver is able to communicate with its peer router.

Parameters
{ [-fields <fieldname>, ...]
  If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

[-instance ]
  If you specify the -instance parameter, the command displays detailed information about all fields.

[-node <nodename> | local] - Node
  This parameter selects the BGP status that match the specified node.

[-vserver <vserver name>] - Vserver
  This parameter selects the BGP status for specified vserver.

[-ipv4-status {unknown|unconfigured|up|down}] - IPv4 status
  This parameter selects the BGP status that matches the specified status for IPv4 address family.

[-ipv6-status {unknown|unconfigured|up|down}] - IPv6 status
  This parameter selects the BGP status that matches the specified status for IPv6 address family.

Examples

<table>
<thead>
<tr>
<th>Node</th>
<th>vserver</th>
<th>IPv4 status</th>
<th>IPv6 status</th>
</tr>
</thead>
<tbody>
<tr>
<td>node1</td>
<td>vs1</td>
<td>up</td>
<td>up</td>
</tr>
</tbody>
</table>

network bgp peer-group commands
Manage BGP peer-group

network bgp peer-group create
Create a new BGP peer group

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The network bgp peer-group create command is used to create a border gateway protocol (BGP) peer group. A BGP peer group will advertise VIP routes for the list of vservers in the peer group's vserver-list using the BGP LIF of the peer group. A BGP peer group will advertise VIP routes to a peer router using the border gateway protocol. The address of the peer router is identified by the peer-address value.

Parameters
-ipspace <IPspace> - IPspace Name
  This parameter specifies the IPspace of the peer group being created.

-peer-group <text> - Peer Group Name
  This parameter specifies the name of the peer group being created.
- **bgp-lif <lif-name>** - BGP LIF
  This parameter specifies the BGP interface (BGP LIF) of the peer group being created.

- **peer-address <IP Address>** - Peer Router Address
  This parameter specifies the IP address of the peer router for the peer group being created.

[-**peer-asn <integer>**] - Peer Router Autonomous number
  This parameter specifies the peer router autonomous system number (ASN) in the peer group being created. The default value is the value of the local node’s ASN.

- **route-preference <integer>** - Route Preference
  This parameter specifies the preference field in BGP update messages for VIP routes. If a router receives multiple VIP route announcements for the same VIP LIF from different BGP LIFs, it will install the one that has the highest preference value. The default route preference value is 100.

### Examples

```
cluster1::> network bgp peer-group create -peer-group group1 -ipspace Default -bgp-lif bgp_lif -peer-address 10.0.1.112
```

### network bgp peer-group delete

Delete a BGP peer group

**Availability:** This command is available to `cluster` administrators at the `admin` privilege level.

**Description**
The `network bgp peer-group delete` command is used to delete border gateway protocol (BGP) peer group configuration.

**Parameters**

- **-ipspace <IPspace>** - IPspace Name
  This parameter specifies the IPspace of the BGP peer group being deleted.

- **-peer-group <text>** - Peer Group Name
  This parameter specifies the name of the BGP peer group being deleted.

### Examples

```
cluster1::> network bgp peer-group delete -ipspace Default -peer-group group1
```

### network bgp peer-group modify

Modify a BGP peer group

**Availability:** This command is available to `cluster` administrators at the `admin` privilege level.

**Description**
The `network bgp peer-group modify` command is used to modify a border gateway protocol (BGP) peer group configuration.
Parameters

- `ipspace <IPspace>` - IPspace Name
  
  This parameter specifies the IPspace of the peer group being modified.

- `peer-group <text>` - Peer Group Name
  
  This parameter specifies the name of the peer group being modified.

- `[peer-address <IP Address>]` - Peer Router Address
  
  This parameter specifies an updated value for the IP address of the peer router.

Examples

```
cluster1::> network bgp peer-group modify -ipspace Default -peer-group peer1 -peer-address 10.10.10.10
```

network bgp peer-group rename

Rename a BGP peer group

Availability: This command is available to cluster administrators at the advanced privilege level.

Description

The `network bgp peer-group rename` command is used to assign a new name to a BGP peer group.

Parameters

- `ipspace <IPspace>` - IPspace Name
  
  This parameter specifies the IPspace of the peer group being renamed.

- `peer-group <text>` - Peer Group Name
  
  The name of the peer group to be updated.

- `new-name <text>` - New Name
  
  The new name for the peer group.

Examples

```
cluster1::> network bgp peer-group rename -peer-group old_name -new-name new_name
```

network bgp peer-group show

Display BGP peer groups information

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The `network bgp peer-group show` command displays the BGP peer groups configuration.

Parameters

```
{ [-fields <fieldname>, ...] }
```

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.
If you specify the -instance parameter, the command displays detailed information about all fields.

[-ipspace <IPspace>] - IPspace Name
This parameter selects peer groups that match the specified IPspace.

[-peer-group <text>] - Peer Group Name
This parameter selects peer groups that match the specified name.

[-bgp-lif <lif-name>] - BGP LIF
This parameter selects peer groups that match the specified BGP Interface.

[-peer-address <IP Address>] - Peer Router Address
This parameter selects peer groups that match the specified peer router address.

[-peer-asn <integer>] - Peer Router Autonomous number
This parameter selects peer groups that match the specified autonomous system number.

[-state <BGP Session State>] - Peer Group State
This parameter selects peer groups that match the specified BGP session state.

[-bgp-node <nodename>] - BGP LIF Node
This parameter selects peer groups that match the specified bgp-node value. This value is calculated based on the current node of the corresponding BGP LIF.

[-bgp-port <netport>] - BGP LIF Port
This parameter selects peer groups that match the specified bgp-port value. This value is calculated based on the current port of the associated BGP LIF.

[-route-preference <integer>] - Route Preference
This parameter selects peer groups that match the specified route preference value.

Examples

```
cluster1::> network bgp peer-group show
IPspace: Default
Peer Group       Local BGP Peer router                      Autonomous Number
               Interface Address/subnet    state          Number     Node   Port
----------  --------- ----------------- -------------- ---------- ------ -----
gp1         bgp_lif1  10.0.5.37         up                     10 node1  e1a
gp2         bgp_lif2  10.0.6.38         up                     12 node1  e2a
```

network cloud commands
Manage cloud-based features

network cloud routing-table commands
Manage external routing tables

network cloud routing-table create
Create a new external routing table

Availability: This command is available to cluster administrators at the advanced privilege level.
Description
The `network cloud routing-table create` command creates a new external routing table.

Parameters
- `route-table-id <text>` - Route Table ID
  
  This parameter is used to provide the name of the external routing table to be created.

Examples

The following example creates an external routing table "eni-123456":

```
cluster1::> network cloud routing-table create -route-table-id eni-123456
```

network cloud routing-table delete
Delete an existing external routing table

Availability: This command is available to `cluster` administrators at the `advanced` privilege level.

Description
The `network cloud routing-table delete` deletes an existing external routing table.

Parameters
- `route-table-id <text>` - Route Table ID
  
  This parameter is used to provide the name of an existing external routing table to be deleted.

Examples

The following example deletes the external routing table "eni-123456":

```
cluster1::> network cloud routing-table delete -route-table-id eni-123456
```

network connections commands
The connections directory

network connections active commands
The active directory

network connections active show
Show the active connections in this cluster

Availability: This command is available to `cluster` and `Vserver` administrators at the `admin` privilege level.

Description
The `network connections active show` command displays information about active network connections.

Note: The results of this command set are refreshed independently every 30 seconds and might not reflect the immediate state of the system.
Parameters

```
[-fields <fieldname>, ...]
```

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

```
[-print-ip-addresses]
```

Print IP addresses for remote hosts -- do not attempt to resolve the addresses to a hostname.

```
[-instance]]
```

If you specify the `-instance` parameter, the command displays detailed information about all fields.

```
[-node <nodename>|local] - Node
```

Selects the connections that match this parameter value.

```
[-cid <Cid>] - Connection ID
```

Selects the connections that match this parameter value.

```
[-vserver <vserver>] - Vserver
```

Selects the connections that match this parameter value.

```
[-lif-name <lif-name>] - Logical Interface Name
```

Selects the connections that match this parameter value.

```
[-local-address <IP Address>] - Local IP address
```

Selects the connections that match this parameter value.

```
[-local-port <integer>] - Local Port
```

Selects the connections that match this parameter value.

```
[-remote-ip <InetAddress>] - Remote IP Address
```

Selects the connections that match this parameter value.

```
[-remote-host <Remote IP>] - Remote Host
```

Selects the connections that match this parameter value.

```
[-remote-port <integer>] - Remote Port
```

Selects the connections that match this parameter value.

```
[-proto {UDP|TCP}] - Protocol
```

Selects the connections that match this parameter value. Possible values are tcp (TCP), udp (UDP), and NA (not applicable).

```
[-lifid <integer>] - Logical Interface ID
```

Selects the connections that match this parameter value.

```
[-service <protocol service>] - Protocol Service
```

Selects the connections that match this parameter value. Possible values include: nfs, iscsi, and loopback.

```
[-lru {yes|no}] - Least Recently Used
```

Selects the connections that match this parameter value.

```
[-blocks-lb {true|false}] - Connection Blocks Load Balance Migrate
```

Selects the logical interfaces that are blocked (true) or not blocked (false) from migrating due to an active client connection.

**Examples**

The following example displays information about active network connections for the node named node0:
At privilege levels above "admin", the command displays an extra column.

network connections active show-clients

Show a count of the active connections by client

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The network connections active show-clients command displays information about client connections, including the client's IP address and the number of client connections.

Note: The results of this command set are refreshed independently every 30 seconds and might not reflect the immediate state of the system.

Parameters

[-fields <fieldname>, ...
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

[-instance]
If you specify the -instance parameter, the command displays detailed information about all fields.
[-node {<nodename>|local}] - Node
Use this parameter to display information only about the connections on the node you specify.

[-vserver <vserver>] - Vserver
This parameter is used by the system to break down the output per vserver.

[-remote-address <Remote IP>] - Remote IP Address
Use this parameter to display information only about the connections that use the remote IP address you specify.

[-count <integer>] - Client Count
Use this parameter to only clients with the number of active client connections you specify.

Examples
The following example displays information about active client connections:

<table>
<thead>
<tr>
<th>Node</th>
<th>Vserver Name</th>
<th>Client IP Address</th>
<th>Count</th>
</tr>
</thead>
<tbody>
<tr>
<td>node0</td>
<td>vs1</td>
<td>192.0.2.253</td>
<td>1</td>
</tr>
<tr>
<td></td>
<td>vs2</td>
<td>192.0.2.252</td>
<td>2</td>
</tr>
<tr>
<td></td>
<td>vs3</td>
<td>192.0.2.251</td>
<td>5</td>
</tr>
<tr>
<td>node1</td>
<td>vs1</td>
<td>192.0.2.250</td>
<td>1</td>
</tr>
<tr>
<td></td>
<td>vs2</td>
<td>192.0.2.252</td>
<td>3</td>
</tr>
<tr>
<td></td>
<td>vs2</td>
<td>customer.example.com</td>
<td>4</td>
</tr>
</tbody>
</table>

network connections active show-lifs
Show a count of the active connections by logical interface

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The network connections active show-lifs command displays the number of active connections on each logical interface, organized by node and Vserver.

Note: The results of this command set are refreshed independently every 30 seconds and might not reflect the immediate state of the system.

Parameters
{| [-fields <fieldname>, ...]
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

| [-instance ]
If you specify the -instance parameter, the command displays detailed information about all fields.

[-node {<nodename>|local}] - Node
Use this parameter to display information only about the connections on the node you specify.

[-vserver <vserver>] - Vserver
Use this parameter to display information only about the connections that are using the node or Vserver you specify.

[-lif-name <lif-name>] - Logical Interface Name
Use this parameter to display information only about the connections that are using the logical interface you specify.
[-count <integer>] - Client Count
Use this parameter to display only logical interfaces with the number of active client connections you specify.

[-blocked-count <integer>] - [DEPRECATED] - Load Balancing Blocking Count
Note: This parameter has been deprecated and may be removed in a future version of Data ONTAP.
Use this parameter to display information only about data logical interfaces blocked from migrating and the connection that is blocking it.

Examples
The following example displays information about the servers and logical interfaces being used by all active connections:

```
cluster1::> network connections active show-lifs
Node       Vserver Name  Interface Name  Count
--------  ------------  --------------- -----
node0      vs0           datalif1             3
          vs0           cluslif1             6
          vs0           cluslif2             5
node1      vs0           datalif2             3
          vs0           cluslif1             3
          vs0           cluslif2             5
node2      vs1           datalif2             1
          vs1           cluslif1             5
          vs1           cluslif2             3
node3      vs1           datalif1             1
          vs1           cluslif1             2
          vs1           cluslif2             1
```

At privilege levels above “admin”, the command displays an extra column.

```
cluster1::*> network connections active show-lifs
Node       Vserver Name  Interface Name  Count  Blocking
--------  ------------  --------------- ------ ----------
node0      vs0           datalif1             3          0
          vs0           cluslif1             6          0
          vs0           cluslif2             5          2
node1      vs0           datalif2             3          0
          vs0           cluslif1             3          0
          vs0           cluslif2             5          0
node2      vs1           datalif2             1          0
          vs1           cluslif1             5          0
          vs1           cluslif2             3          2
node3      vs1           datalif1             1          0
          vs1           cluslif1             2          0
          vs1           cluslif2             1          0
```

network connections active show-protocols
Show a count of the active connections by protocol

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The network connections active show-protocols command displays the number of active connections per protocol, organized by node.
Note: The results of this command set are refreshed independently every 30 seconds and might not reflect the immediate state of the system.

Parameters

{-fields <fieldname>,...}
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use -fields ? to display the fields to specify.

{-instance}
If you specify the -instance parameter, the command displays detailed information about all fields.

{-node <nodename>|local]} - Node
Use this parameter to display information only about the connections on the node you specify.

{-vserver <vserver>} - Vserver
This parameter is used by the system to break down the output per vserver.

{-proto {UDP|TCP]} - Protocol
Use this parameter to display information only about the connections that use the network protocol you specify. Possible values include tcp (TCP), udp (UDP), and NA (not applicable).

{-count <integer>} - Client Count
Use this parameter to display only protocols with the number of active client connections you specify.

Examples

The following example displays information about all network protocols being used by active connections:

<table>
<thead>
<tr>
<th>Node</th>
<th>Vserver Name</th>
<th>Protocol</th>
<th>Count</th>
</tr>
</thead>
<tbody>
<tr>
<td>node0</td>
<td>vs1</td>
<td>UDP</td>
<td>19</td>
</tr>
<tr>
<td>node0</td>
<td>vs1</td>
<td>TCP</td>
<td>11</td>
</tr>
<tr>
<td>node0</td>
<td>vs2</td>
<td>UDP</td>
<td>17</td>
</tr>
<tr>
<td>node1</td>
<td>vs1</td>
<td>UDP</td>
<td>14</td>
</tr>
<tr>
<td>node1</td>
<td>vs2</td>
<td>TCP</td>
<td>10</td>
</tr>
</tbody>
</table>

network connections active show-services

Show a count of the active connections by service

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description

The network connections active show-services command displays the number of active connections by protocol service, organized by node.

Note: The results of this command set are refreshed independently every 30 seconds and might not reflect the immediate state of the system.

Parameters

{-fields <fieldname>,...}
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use -fields ? to display the fields to specify.

{-instance}
If you specify the -instance parameter, the command displays detailed information about all fields.
[-node {<nodename>|local}] - Node

Use this parameter to display information only about the connections on the node you specify.

[-vserver <vserver>] - Vserver

This parameter is used by the system to break down the output per vserver.

[-service <protocol service>] - Protocol Service

Use this parameter to display information only about the connections that use the protocol service you specify. Possible values include: nfs, iscsi, and loopback.

[-count <integer>] - Client Count

Use this parameter to display information only about protocol services with the number of active client connections you specify.

Examples

The following example displays information about all protocol services being used by active connections:

```
cluster1::> network connections active show-services

<table>
<thead>
<tr>
<th>Node</th>
<th>Vserver Name</th>
<th>Service</th>
<th>Count</th>
</tr>
</thead>
<tbody>
<tr>
<td>node0</td>
<td>vs1</td>
<td>mount</td>
<td>3</td>
</tr>
<tr>
<td></td>
<td>vs1</td>
<td>nfs</td>
<td>14</td>
</tr>
<tr>
<td></td>
<td>vs1</td>
<td>nlm_v4</td>
<td>4</td>
</tr>
<tr>
<td></td>
<td>vs1</td>
<td>cifs_srv</td>
<td>3</td>
</tr>
<tr>
<td></td>
<td>vs1</td>
<td>port_map</td>
<td>18</td>
</tr>
<tr>
<td></td>
<td>vs2</td>
<td>rclopcp</td>
<td>27</td>
</tr>
<tr>
<td>node1</td>
<td>vs1</td>
<td>nfs</td>
<td>5</td>
</tr>
<tr>
<td></td>
<td>vs2</td>
<td>rclopcp</td>
<td>12</td>
</tr>
<tr>
<td></td>
<td>vs2</td>
<td>nfs</td>
<td>4</td>
</tr>
<tr>
<td></td>
<td>vs2</td>
<td>port_map</td>
<td>8</td>
</tr>
</tbody>
</table>
```

**network connections listening commands**

The listening directory

**network connections listening show**

Show the listening connections in this cluster

**Availability:** This command is available to cluster and Vserver administrators at the admin privilege level.

**Description**

The network connections listening show command displays information about network connections that are in an open and listening state.

**Parameters**

[-fields <fieldname>, ...]

If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use ‘-fields?’ to display the fields to specify.

[-instance]

If you specify the -instance parameter, the command displays detailed information about all fields.

[-node {<nodename>|local}] - Node

Selects the listening connections that match this parameter value.
[-mgmt-cid <integer>] - Management Connection ID
Selects the listening connections that match this parameter value.

[-vserver <vserver>] - Vserver
Selects the listening connections that match this parameter value.

[-cid <integer>] - System Connection ID
Selects the listening connections that match this parameter value.

[-lif-name <lif-name>] - Logical Interface Name
Selects the listening connections that match this parameter value.

[-local-address <IP Address>] - Local IP Address
Selects the listening connections that match this parameter value.

[-local-port <integer>] - Local Port
Selects the listening connections that match this parameter value.

[-remote-ip <InetAddress>] - Remote IP Address
Selects the listening connections that match this parameter value.

[-remote-host <Remote IP>] - Remote Host
Selects the listening connections that match this parameter value.

[-remote-port <integer>] - Remote Port
Selects the listening connections that match this parameter value.

[-proto {UDP|TCP}] - Protocol
Selects the listening connections that match this parameter value. Possible values include tcp (TCP), udp (UDP), and NA (not applicable).

[-lifid <integer>] - Logical Interface ID
Selects the listening connections that match this parameter value.

[-service <protocol service>] - Protocol Service
Selects the listening connections that match this parameter value. Possible values include: nfs, iscsi, and loopback.

[-lru {yes|no}] - Least Recently Used
Selects the listening connections that match this parameter value.

---

**Examples**

The following example displays information about all listening network connections:

```
cluster1::> network connections listening show
Vserver Name Interface Name:Local Port Protocol/Service
---------- -------------------------- -------------
node0        cluslif1:7700              UDP/rclopcp

8 entries were displayed.
```

The following example displays detailed information about listening network connections for the node named node0:

```
cluster1::> network connections listening show -node node0
Node: node0
Management Connection Id: 0
System Connection Id: 0
```
network device-discovery commands

The device-discovery directory

network device-discovery show

Display device discovery information

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The network device-discovery show command displays information about discovered devices. This information may be useful in determining the network topology or investigating connectivity issues. By default, the command displays the following information:

• Local interface
• Discovered device
• Discovered interface
• Discovered platform

Parameters

[-fields <fieldname>, ...]
Include the specified field or fields in the command output. Use ‘-fields ?’ to display the valid fields.

[-instance ]
Use this parameter to display detailed information about all fields.

[-node <nodename>] · Node
Displays the discovery ports that match the node name.

[-protocol {cdp|lldp}] · Protocol
Displays the devices that are discovered by the given protocol.
[-port <text>] - Port
Displays the discovery ports that match the physical network port. For example, e0a will display devices
discovered on port e0a.

[-discovered-device <text>] - Discovered Device
Displays the discovered devices that match the discovered device name.

[-interface <text>] - Discovered Device Interface
Displays the discovered devices that match this interface port name. The format is dependent on the reporting
device. For example: FastEthernet0/12

[-device-ip <IP Address>, ...] - Discovered Device IP Addresses
Displays the discovered devices that match the IP address(es). At present, only IPv4 addresses are included. It
is recommended to use wildcards around the desired value.

[-platform <text>] - Discovered Device Platform
Displays the discovery ports that contain the platform of discovered devices. For example: N5K-C5010P-BF

[-version <text>] - Discovered Device Version
Displays the discovery ports that contain the version of discovered devices.

[-chassis-id <text>] - Discovered Device Chassis ID
Displays the discovered devices that match the chassis ID.

[-system-name <text>] - Discovered Device System Name
Displays the discovered devices that match the system name.

[-hold-time-remaining <integer>] - Discovered Device's Remaining Hold Time
Displays the discovered devices that match the remaining packet hold time in seconds. If an advertisement
from the device isn't received before this time reaches zero, the entry will expire and be removed from the list.
For example, "<120" will display discovered devices which will expire within the next 120 seconds.

[-capabilities (router|trans-bridge|source-route-bridge|switch|host|igmp|repeater|phone), ...] - Discovered Device Capabilities
Displays the discovered devices that match the capability or capabilities. Possible values:

- "router" - Router
- "trans-bridge" - Trans Bridge
- "source-route-bridge" - Source Route Bridge
- "switch" - Switch
- "host" - Host
- "igmp" - IGMP
- "repeater" - Repeater
- "phone" - Phone

Examples

    cluster1::> network device-discovery show

network fcp commands

The fcp directory
Commands used for managing FCP target adapters.

network fcp adapter commands

The adapter directory
Commands used for managing FCP adapters.

network fcp adapter modify

Modify the fcp adapter settings

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**
Modifies the FCP target adapter information.

The adapter argument is in the form Xy or Xy_z where X and z are integers and y is a letter. An example is 4a or 4a_1.

You cannot bring an adapter offline until all logical interfaces connected to that adapter are offline. Use the `network interface modify` command to take your logical interfaces offline.

The speed option sets the Fibre Channel link speed of an adapter. You can set adapters that support:

- 10Gb/s to 10 or auto
- 8Gb/s to 2, 4, 8 or auto
- 4Gb/s to 2, 4 or auto
- 2Gb/s to 2 or auto

By default, the link speed option is set to auto for auto negotiation. Setting the link speed to a specific value disables auto negotiation. Under certain conditions, a speed mismatch can prevent the adapter from coming online.

**Note:** The system reports the actual link speed with the "Data Link Rate (Gbit)" field in the output of `network fcp adapter show -instance`.

**Parameters**

- **-node** `<nodename|local>` - Node
  Specifies the node of the target adapter.
-adapter <text> - Adapter
   Specifies the target adapter.

[-status-admin (down|up)] - Administrative Status
   Specifies the desired (administrative) status of the adapter. To view the actual operational status, run network fcp adapter show -fields status-oper.

[-speed {1|2|4|8|10|16|32|auto}] - Configured Speed
   Specifies the adapter configuration speed in Gigabytes.

Examples

  cluster1::> network fcp adapter modify -node node1 -adapter 0d -speed 2

network fcp adapter show

Display FCP adapters

Availability: This command is available to cluster administrators at the admin privilege level.

Description

Displays FCP target adapter information. You can also use this information to determine if adapters are active and online.

The adapter argument is in the form Xy or Xy_z where X and z are integers and y is a letter. An example is 4a or 4a_1.

Parameters

{ [-fields <fieldname>, ...]
   If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

[[-instance ]]  
   If you specify the -instance parameter, the command displays detailed information about all fields.

[-node {<nodename>|local}] - Node
   If this parameter is specified, the command displays information only about the FCP target adapters that are present on the specified node.

[-adapter <text>] - Adapter
   If this parameter is specified, the command displays information only about the FCP target adapters that match the specified name.

[-description <text>] - Description
   If this parameter is specified, the command displays information only about the FCP target adapters that match the specified description.

[[-physical-protocol {fibre-channel|ethernet}]] - Physical Protocol
   If this parameter is specified, the command displays information only about the FCP target adapters that match the specified physical protocol. Possible values are fibre-channel and ethernet.
[-max-speed (1|2|4|8|10|16|32|auto)] - Maximum Speed
If this parameter is specified, the command displays information only about the FCP target adapters that match
the specified maximum speed.

[-status-admin {down|up}] - Administrative Status
If this parameter is specified, the command displays information only about the FCP target adapters that match
the administrative state. Possible values are up and down.

[-status-oper <text>] - Operational Status
If this parameter is specified, the command displays information only about the FCP target adapters that match
the specified operational status.

[-status-extended <text>] - Extended Status
If this parameter is specified, the command displays information only about the FCP target adapters that match
the specified extended status.

[-portaddr <Hex Integer>] - Host Port Address
If this parameter is specified, the command displays information only about the FCP target adapters connected
with the specified fabric port address.

[-firmware-rev <text>] - Firmware Revision
If this parameter is specified, the command displays information only about the FCP target adapters that match
the specified firmware revision.

[-data-link-rate <integer>] - Data Link Rate (Gbit)
If this parameter is specified, the command displays information only about the FCP target adapters that match
the specified data link rate.

[-fabric-established {true|false}] - Fabric Established
If this parameter is specified, the command displays information only about the FCP target adapters that match
the specified fabric login establishment state.

[-fabric-name <text>] - Fabric Name
If this parameter is specified, the command displays information only about the FCP target adapters that are
logged in to the fabric with the specified WWN.

[-conn-established {loop|ptp}] - Connection Established
If this parameter is specified, the command displays information only about the FCP target adapters that match
the specified connection type. Possible values are loop and ptp.

[-is-conn-established {true|false}] - Is Connection Established
If this parameter is specified, the command displays information only about the FCP target adapters that match
the specified connection established state.

[-media-type {loop|ptp|auto}] - Mediatype
If this parameter is specified, the command displays information only about the FCP target adapters that match
the specified configured media type. Possible values are loop, ptp, and auto.

[-speed (1|2|4|8|10|16|32|auto)] - Configured Speed
If this parameter is specified, the command displays information only about the FCP target adapters that match
the specified configured speed. If the adapter is set to auto-negotiate, then the value will be auto.

[-data-protocols-supported {fcp|fc-nvme}, ...] - Data Protocols Supported
If this parameter is specified, the command displays information only about the FCP target adapters that may
host LIFs with the specified data protocol. Possible values are fcp and fc-nvme.

[-fc-wwnn <text>] - Adapter WWNN
If this parameter is specified, the command displays information only about the FCP target adapters that match
the specified world wide node name.
[-fc-wwpn <text>] - Adapter WWPN
   If this parameter is specified, the command displays information only about the FCP target adapters that match
   the specified world wide port name.

[-switch-port <text>] - Switch Port
   If this parameter is specified, the command displays information only about the FCP target adapters that are
   connected to the specified switch port.

[-sfp-formfactor <text>] - Form Factor Of Transceiver
   If this parameter is specified, the command displays information only about the FCP target adapters that match
   the specified SFP form factor.

[-sfp-vendor-name <text>] - Vendor Name Of Transceiver
   If this parameter is specified, the command displays information only about the FCP target adapters that match
   the specified SFP vendor name.

[-sfp-part-number <text>] - Part Number Of Transceiver
   If this parameter is specified, the command displays information only about the FCP target adapters that match
   the specified SFP part number.

[-sfp-rev <text>] - Revision Of Transceiver
   If this parameter is specified, the command displays information only about the FCP target adapters that match
   the specified SFP revision number.

[-sfp-serial-number <text>] - Serial Number Of Transceiver
   If this parameter is specified, the command displays information only about the FCP target adapters that match
   the specified SFP serial number.

[-sfp-fc-speed-capabilities <text>] - FC Capabilities Of Transceiver
   If this parameter is specified, the command displays information only about the FCP target adapters that match
   the specified SFP speed capabilities.

[-sfp-vendor-oui <text>] - Vendor OUI Of Transceiver
   If this parameter is specified, the command displays information only about the FCP target adapters that match
   the specified SFP vendor OUI.

[-sfp-wavelength <integer>] - Wavelength In Nanometers
   If this parameter is specified, the command displays information only about the FCP target adapters that match
   the specified SFP wavelength.

[-sfp-date-code <text>] - Date Code Of Transceiver
   If this parameter is specified, the command displays information only about the FCP target adapters that match
   the specified SFP date code.

[-is-sfp-optical-transceiver-valid {true|false}] - Validity Of Transceiver
   If this parameter is specified, the command displays information only about the FCP target adapters that match
   whether the SFP is installed and valid.

[-sfp-connector <text>] - Connector Used
   If this parameter is specified, the command displays information only about the FCP target adapters that match
   the specified SFP connector type.

[-sfp-encoding <text>] - Encoding Used
   If this parameter is specified, the command displays information only about the FCP target adapters that match
   the specified SFP physical encoding.

[-is-sfp-diagnostics-internally-calibrated {true|false}] - Is Internally Calibrated
   If this parameter is specified, the command displays information only about the FCP target adapters that match
   whether the SFP diagnostics are internally calibrated or not.
[-sfp-rx-power <text>] - Received Optical Power
If this parameter is specified, the command displays information only about the FCP target adapters that match
the specified observed SFP receive power.

[-is-sfp-rx-power-in-range {true|false}] - Is Received Power In Range
If this parameter is specified, the command displays information only about the FCP target adapters that match
whether the observed SFP receive power is within the valid range for the SFP.

[-sfp-tx-power <text>] - SFP Transmitted Optical Power
If this parameter is specified, the command displays information only about the FCP target adapters that match
the specified SFP transmit power.

[-is-sfp-tx-power-in-range {true|false}] - Is Xmit Power In Range
If this parameter is specified, the command displays information only about the FCP target adapters that match
whether the observed SFP transmit power is within the valid range for the SFP.

Examples

```
Example 1:
cluster1::> fcp adapter show
Connection  Host
Node         Adapter Established Port Address
------------ ------- ----------- ------------
sti6280-021   0a      ptp         30012c
```

The example above displays information regarding FCP adapters within cluster1.

```
Example 2:
cluster1::> fcp adapter show -instance -node sti6280-021 -adapter 0a
Node: sti6280-021
Adapter: 0a
Description: Fibre Channel Target Adapter 0a (QLogic 2532 (2562), rev. 2, 8G)
Physical Protocol: fibre-channel
Maximum Speed: 8
Administrative Status: up
Operational Status: online
Extended Status: ADAPTER UP
Host Port Address: 30012c
Firmware Revision: 5.8.0
Data Link Rate (Gbit): 4
Fabric Established: true
Fabric Name: 20:14:54:7f:ee:54:b9:01
Connection Established: ptp
Is Connection Established: true
Mediatype: ptp
Configured Speed: auto
Adapter WWNN: 50:0a:09:80:8f:7f:8b:1c
Adapter WWPN: 50:0a:09:81:8f:7f:8b:1c
Switch Port: RTP-AG01-410B51:1/41
Form Factor Of Transceiver: SFP
Vendor Name Of Transceiver: OPNEXT,INC
Part Number Of Transceiver: TRS2000EN-SC01
Revision Of Transceiver: 0000
Serial Number Of Transceiver: T10664793
FC Capabilities Of Transceiver: 10 (Gbit/sec)
Vendor OUI Of Transceiver: 0:11:64
Wavelength In Nanometers: 850
Date Code Of Transceiver: 10:08:17
Validity Of Transceiver: true
Connector Used: LC
Encoding Used: 64B66B
Is Internally Calibrated: true
Received Optical Power: 441.3 (uWatts)
Is Received Power In Range: true
SFP Transmitted Optical Power: 600.4 (uWatts)
Is Xmit Power In Range: true

network fcp topology commands

The topology directory

network fcp topology show

FCP topology interconnect elements per adapter

Availability: This command is available to cluster administrators at the admin privilege level.

Description
Display FCP topology interconnect elements per adapter.

Parameters

- [ -fields <fieldname>, ... ]
  If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use -fields ? to display the fields to specify.

- [-instance ]
  If you specify the -instance parameter, the command displays detailed information about all fields.

- [ -node {<nodename>|local} - Node ]
  Use this parameter to select the interconnect elements for adapters that are located on the node that you specify.

- [-adapter <text>] - Adapter
  Use this parameter to select the interconnect elements for the specified adapter.

- [-domain-id <integer>] - Domain Id
  Use this parameter to select the interconnect elements with the specified domain identifier.

- [-port-wwpn <text>] - Port WWPN
  Use this parameter to select the interconnect elements with the specified port world wide name.

- [-switch-name <text>] - Switch Name
  Use this parameter to select the interconnect elements with the specified switch.

- [-switch-vendor <text>] - Switch Vendor
  Use this parameter to select the interconnect elements with the specified vendor.

- [-switch-release <text>] - Switch Release
  Use this parameter to select the interconnect elements with the specified release.

- [-switch-wwn <text>] - Switch WWN
  Use this parameter to select the interconnect elements with the specified world wide name.

- [-port-count <integer>] - Port Count
  Use this parameter to select the interconnect elements with the specified port count.

- [-port-slot <text>] - Port Slot
  Use this parameter to select the interconnect elements with the specified port slot.

- [-port-state {Unknown|Online|Offline|Testing|Fault}] - Port State
  Use this parameter to select the interconnect elements with the specified port state.

- [-port-type {None|N-Port|NL-Port|FNL-Port|NX-Port|F-Port|FL-Port|E-Port|B-Port|TNP-Port|TF-Port|NV-Port|FV-Port|SD-Port|TE-Port|TL-Port}] - Port Type
  Use this parameter to select the interconnect elements with the specified port type.
[-port-attached-wwpn <text>] - Attached Port WWPN
Use this parameter to select the interconnect elements with the specified attached wwpn.

[-port-attached-id <text>] - Attached Port Id
Use this parameter to select the interconnect elements with the specified attached id.

[-port-attached-visible <text>] - Visible
Use this parameter to select the interconnect elements with the specified visibility flag on attached port structure.

**network fcp zone show**

Display the active zone set information

Availability: This command is available to *cluster* administrators at the *admin* privilege level.

Description
Displays the active zone set information.

Parameters

```
[-fields <fieldname>, ...]
```

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `'-fields ?' to display the fields to specify.

```
[-instance]
```

If you specify the `-instance` parameter, the command displays detailed information about all fields.

network fcp commands 333
[-node {<nodename>|local}] - Node
Use this parameter to select the active zone set information for adapters that located on the node name that you specify.

[-adapter <text>] - Adapter
Use this parameter to select the active zone set information for the specified adapter.

[-zoneset-name <text>] - Zoneset Name
Use this parameter to select the active zone set information for the specified zone set name.

[-zone-name <text>] - Zone Name
Use this parameter to select the active zone set information for the specified zone name.

[-unique <integer>] - Unique
A unique index for each zoneset record.

[-type-name <text>] - Type Name
Use this parameter to select the active zone set information with the specified symbolic type.

[-type <integer>] - Type
Use this parameter to select the active zone set information with the specified port type.

[-port-id <Hex Integer>] - Member Port Id
Use this parameter to select the active zone set information with the specified member port id.

[-domain-id <integer>] - Member Domain Id
Use this parameter to select the active zone set information with the specified member domain id.

[-port <integer>] - Member Port
Use this parameter to select the active zone set information with the specified member port.

[-wwn <text>] - Member WWN
Use this parameter to select the active zone set information with the specified member WWN.

[-zone-count <integer>] - Zone Count
Use this parameter to select the active zone set information with the specified number of zones.

[-zone-member-count <integer>] - Zone Member Count
Use this parameter to select the active zone set information with the specified number of zone members in a zone.

network interface commands

Manage logical interfaces

network interface create

Create a logical interface

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The network interface create command creates a logical interface (LIF).

Note: A logical interface is an IP address associated with a physical network port. For logical interfaces using NAS data protocols, the interface can fail over or be migrated to a different physical port in the event of component failures, thereby continuing to provide network access despite the component failure. Logical interfaces using SAN data protocols do not support migration or failover.

Note: On some cloud platforms, this operation might perform changes to the external route tables.

Parameters
-vserver <vserver> - Vserver Name
Use this parameter to specify the Vserver on which the LIF is created.

-lif <lif-name> - Logical Interface Name
Use this parameter to specify the name of the LIF that is created. For iSCSI and FC LIFs, the name cannot be more than 254 characters.

[service-policy <text>] - Service Policy
Use this parameter to specify a service policy for the LIF. If no policy is specified, a default policy will be assigned automatically. Use the network interface service-policy show command to review available service policies.

-role {cluster|node-mgmt|intercluster|cluster-mgmt} - (DEPRECATED)-Role
Note: This parameter has been deprecated and may be removed in a future version of ONTAP. Use the -service-policy parameter instead.
Use this parameter to specify the role of the LIF. LIFs can have one of five roles:
• Cluster LIFs, which provide communication among the nodes in a cluster
• Intercluster LIFs, which provide communication among peered clusters
• Data LIFs, which provide data access to NAS and SAN clients
• Node-management LIFs, which provide access to cluster management functionality
• Cluster-management LIFs, which provide access to cluster management functionality

LIFs with the cluster-management role behave as LIFs with the node-management role except that cluster-management LIFs can failover between nodes.

[data-protocol {nfs|cifs|iscsi|fcp|fcache|none|fc-nvme}, ...] - Data Protocol
Use this parameter to specify the list of data protocols that can be configured on the LIF. The supported protocols are NFS, CIFS, iSCSI, FCP, and FC-NVMe. NFS and CIFS are available by default when you create a LIF. If you specify "none", the LIF does not support any data protocols. Also, none, iscsi, fcp or fc-nvme cannot be combined with any other protocols.
Note: The data-protocol field must be specified when the LIF is created and cannot be modified later.

- **address <IP Address>** - Network Address
  Use this parameter to specify the LIF's IP address.
  
  **Note:** A cluster LIF cannot be on the same subnet as a management or data LIF.

| - **netmask <IP Address>** - Netmask |
| Use this parameter to specify the LIF's netmask. |
| - **netmask-length <integer>** - Bits in the Netmask |
| Use this parameter to specify the length (in bits) of the LIF's netmask. |
| - **is-vip [true]** - Is VIP LIF |
| Use this parameter to display only logical interfaces matching a specify "is-vip" flag. Specifying "true" matches only LIFs to implement a Virtual IP; "false" matches only LIFs that do not. |

| - **auto [true]** - Allocate Link Local IPv4 Address |
| Use this parameter to specify whether IPv4 link local addressing is enabled for this LIF. |

| - **subnet-name <subnet name>** | - Subnet Name |
| Use this parameter to allocate the interface address from a subnet. If needed, a default route will be created for this subnet. |

| - **home-node <nodename>** | - Home Node |
| Use this parameter to specify the LIF's home node. The home node is the node to which the LIF returns when the network interface revert command is run on the LIF. |

| - **home-port <netport>|<ifgrp>** | - Home Port |
| Use this parameter to specify the LIF's home port or interface group. The home port is the port or interface group to which the LIF returns when the network interface revert command is run on the LIF. |

| - **status-admin {up|down}** | - Administrative Status |
| Use this parameter to specify whether the initial administrative status of the LIF is up or down. The default setting is up. The administrative status can differ from the operational status. For example, if you specify the status as up but a network problem prevents the interface from functioning, the operational status remains as down. |

| - **failover-policy {system-defined|local-only|sfo-partner-only|disabled|broadcast-domain-wide}** | - Failover Policy |
| Use this parameter to specify the failover policy for the LIF. |
| • system-defined - The system determines appropriate failover targets for the LIF. The default behavior is that failover targets are chosen from the LIF's current hosting node and also from one other non-partner node when possible. |
| • local-only - The LIF fails over to a port on the local or home node of the LIF. |
| • sfo-partner-only - The LIF fails over to a port on the home node or SFO partner only. |
| • broadcast-domain-wide - The LIF fails over to a port in the same broadcast domain as the home port. |
| • disabled - Failover is disabled for the LIF. |
| The failover policy for cluster logical interfaces is local-only and cannot be changed. The default failover policy for data logical interfaces is system-defined. This value can be changed. |

  **Note:** Logical interfaces for SAN protocols do not support failover. Thus, such interfaces will always show this parameter as disabled.
[firewall-policy <policy>] - Firewall Policy

Use this parameter to specify the firewall policy for the LIF. A LIF can use a default firewall policy that corresponds to its role (management, cluster, intercluster, or data) or a custom firewall policy created by an administrator. View and modify existing firewall policies using the system services firewall policy show and system services firewall policy modify commands, respectively.

[auto-revert {true|false}] - Auto Revert

Use this parameter to specify whether a data LIF is automatically reverted to its home node under certain circumstances. These circumstances include startup, when the status of the management database changes to either master or secondary, or when the network connection is made. The default setting is false. If you set the value of this parameter to true, load balancing migration capability of the data LIF is disabled (the -allow-lb-migrate parameter is set to false).

Note: Logical interfaces for SAN traffic do not support auto-revert. Thus, this parameter is always false on such interfaces.

dns-zone {<zone-name>|none} - Fully Qualified DNS Zone Name

Use this parameter to specify a unique, fully qualified domain name of a DNS zone to which this data LIF is added. You can associate a data LIF with a single DNS zone. All data LIFs included in a zone must be on the same Vserver. If a LIF is not added to a DNS zone the data LIF is created with the value none.

[listen-for-dns-query {true|false}] - DNS Query Listen Enable

Use this parameter to specify if the LIF has to listen for DNS queries. The default value for this parameter is true.

[allow-lb-migrate {true|false}] - (DEPRECATED)-Load Balancing Migrate Allowed (privilege: advanced)

Note: This parameter has been deprecated and may be removed in a future version of Data ONTAP.

Use this parameter to specify whether load balancing migration is activated for this data LIF. The default value of this parameter is false. If you set the value of this parameter to true, automatic revert capability for this data LIF is disabled (the -auto-revert parameter is set to false). Also, data LIFs that migrate as a result of load balancing adhere to network interface failover rules.

Note: During times when a LIF is hosting active NFSv4, CIFS, or NRV connections, load balancing based LIF migrations between nodes will be temporarily disabled.

[lb-weight {load|0..100}] - Load Balanced Weight (privilege: advanced)

Use this parameter to specify a load balancing weight for a data LIF. A valid numeric load balancing weight is any integer between 0 and 100. When you specify the same load balancing weight for all data LIFs in a DNS zone, client requests are uniformly distributed, similar to round-robin DNS. A data LIF with a low load balancing weight is made available for client requests less frequently than one that has a high load balancing weight. "load" is the default value of this parameter. If set to "load", node utilization statistics are used to dynamically assign the load balancing weight.

failover-group <failover-group> - Failover Group Name

Use this parameter to specify the name of the failover group to associate with the LIF. Manage failover groups by using the network interface failover-groups command. Each broadcast domain has a default failover group which is created by the system automatically and has the same name as the broadcast domain. The failover group associated with the broadcast domain includes all ports in the broadcast domain. A logical interface’s failover group is set to the failover group of the home port's broadcast domain by default, but this value can be modified.

Note: Logical interfaces for SAN protocols do not support failover. Thus, this parameter cannot be specified for such interfaces.

[comment <text>] - Comment

Use this parameter to specify the comment to associate with the LIF.
[-force-subnet-association true] - Force the LIF's Subnet Association

This command will fail if the IP address falls within the address range of a named subnet. Set this to true to acquire the address from the named subnet and assign the subnet to the LIF.

[-is-dns-update-enabled true|false] - Is Dynamic DNS Update Enabled?

If this parameter is set to true, then dynamic DNS update is sent to the DNS server for the particular LIF entry if dynamic DNS updates are enabled for the corresponding Vserver. This field is set to true by default for both IPv4 and IPv6 LIFs. DNS Update is not supported on LIFs not configured with either the NFS or CIFS protocol.

[-probe-port <integer>] - Probe-port for Azure ILB

Use this parameter to specify a probe-port for the LIF in the Azure environment. It is a required field in the Azure environment. If no probe-port is specified, an error would be returned.

Examples

The following example creates an IPv4 LIF named datalif1 and an IPv6 LIF named datalif2 on a Vserver named vs0. Their home node is node0 and home port is e0c. The failover policy broadcast-domain-wide is assigned to both LIFs. The firewall policy is data and the LIFs are automatically reverted to their home node at startup and under other circumstances. The datalif1 has the IP address 192.0.2.130 and netmask 255.255.255.128, and datalif2 has the IP address 3ffe:1::aaaa and netmask length of 64.

```
cluster1::> network interface create -vserver vs0 -lif datalif1 -role data -home-node node0 -home-port e0c -address 192.0.2.130 -netmask 255.255.255.128 -failover-policy broadcast-domain-wide -firewall-policy data -auto-revert true
cluster1::> network interface create -vserver vs0 -lif datalif2 -role data -home-node node0 -home-port e0c -address 3ffe:1::aaaa -netmask-length 64 -failover-policy broadcast-domain-wide -firewall-policy data -auto-revert true
```

network interface delete

Delete a logical interface

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The network interface delete command deletes a logical interface (LIF) from a Vserver. Only administratively down LIFs can be deleted. To make a LIF administratively down, use the network interface modify command to set the "status-admin" parameter to "down".

Note: If the LIF is configured for a SAN protocol and is part of a port set, the LIF must be removed from the port set before it can be deleted. To determine if a LIF is in a port set, use the lun portset show command. To remove the LIF from the port set, use the lun portset remove command.

Note: On some cloud platforms, this operation might perform changes to the external route tables.

Parameters

-vserver <vserver> - Vserver Name

Use this parameter to specify the Vserver on which the logical interface to be deleted is located.
-lif <lif-name> - Logical Interface Name

Use this parameter to specify the logical interface to delete.

Examples
The following example deletes a logical interface named cluslif3 that is located on a Vserver named vs0.

```
cluster1::> network interface delete -vserver vs0 -lif cluslif3
```

Related references
network interface modify on page 340

lun portset remove on page 225

network interface migrate

Migrate a logical interface to a different port

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The network interface migrate command migrates a logical interface to a port or interface group on the node you specify.

Note: Manual migration of a logical interface can take up to 15 seconds to complete. Also, when you migrate a cluster logical interface, you must do so from the local node. Logical interface migration is a best-effort command, and can only be completed if the destination node and port are operational

Note: Logical interfaces for SAN protocols do not support migration. Attempts to do so will result in an error.

Note: On some cloud platforms, this operation might perform changes to the external route tables.

Parameters
-vserver <vserver> - Vserver Name
Use this parameter to specify the Vserver that owns the logical interface that is to be migrated.

-lif <lif-name> - Logical Interface Name
Use this parameter to specify the logical interface that is to be migrated.

-destination-node <nodename> - Destination Node
Use this parameter to specify the node to which the logical interface is to be migrated.

[-destination-port (<netport>|<ifgrp>)] - Destination Port
Use this parameter to specify the port or interface group to which the logical interface is to be migrated.

[-force [true]] - Force Migrate Data LIF Flag (privilege: advanced)
Use this parameter to force the migration operation.

Examples
The following example migrates a logical interface named datalif1 on a Vserver named vs0 to port e0c on a node named node2:

```
cluster1::> network interface migrate -vserver vs0 -lif datalif1 -dest-node node2 -dest-port e0c
```
**network interface migrate-all**

Migrate all data logical interfaces away from the specified node

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**
The `network interface migrate-all` command migrates all data logical interfaces from the node you specify.

**Note:** Manual migration of a logical interface can take up to 15 seconds to complete. Logical interface migration is a best-effort command and can only be completed if the destination node and port are operational. Logical interface migration requires that the logical interface be pre-configured with valid failover rules to facilitate failover to a remote node.

**Note:** Logical interfaces for SAN protocols do not support migration. Attempts to do so will result in an error.

**Note:** On some cloud platforms, this operation might perform changes to the external route tables.

**Parameters**

- `node <nodename>` - Node
  
  Use this parameter to specify the node from which all logical interfaces are migrated. Each data logical interface is migrated to another node in the cluster, assuming that the logical interface is configured with failover rules that specify an operational node and port.

- `[-port (netport|ifgrp)]` - Port
  
  Use this parameter to specify the port from which all logical interfaces are migrated. This option cannot be used with asynchronous migrations. If this parameter is not specified, then logical interfaces will be migrated away from all ports on the specified node.

**Examples**
The following example migrates all data logical interfaces from the current (local) node.

```
cluster1::> network interface migrate-all -node local
```

---

**network interface modify**

Modify a logical interface

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**
The `network interface modify` command modifies attributes of a logical interface (LIF).

**Note:** You cannot modify some properties of an iSCSI or FCP LIF, such as `-home-node` or `-home-port`, if the LIF is in a port set. To modify these properties, first remove the LIF from the port set. To determine if a LIF is in a port set, use the `lun portset show` command. To remove the LIF from the port set, use the `lun portset remove` command.

**Note:** On some cloud platforms, this operation might perform changes to the external route tables.

**Parameters**

- `vserver <vserver>` - Vserver Name
  
  Use this parameter to specify the Vserver on which the LIF to be modified is located.

- `lif <lif-name>` - Logical Interface Name
  
  Use this parameter to specify the name of the LIF that is to be modified
Use this parameter to modify the service policy associated with the LIF.

Use this parameter to modify the LIF’s IP address.

Note: A cluster LIF cannot be on the same subnet as a data or management LIF.

Use this parameter to modify the LIF’s netmask.

Use this parameter to modify the length (in bits) of the LIF’s netmask.

Use this parameter to allocate the interface address from a subnet. Modifying this parameter will cause a new IP address to be allocated and assigned to the interface.

Use this parameter to modify the LIF’s home node. The home node is the node to which the LIF returns when the network interface revert command is run on that LIF.

Use this parameter to modify the LIF’s home port. The home port is the port or interface group to which the LIF returns when the network interface revert command is run on that LIF.

Note: If you change this parameter for a cluster or management LIF, you must reboot the storage system to force the change to take effect.

Use this parameter to modify the administrative status of the LIF. The administrative status can differ from the operational status. For example, if you specify the status as up but a network problem prevents the interface from functioning, the operational status remains as down.

Use this parameter to modify the failover policy for the LIF.

- system-defined - The system determines appropriate failover targets for the LIF. The default behavior is that failover targets are chosen from the LIF’s current hosting node and also from one other non-partner node when possible.
- local-only - The LIF fails over to a port on the local or home node of the LIF.
- sfo-partner-only - The LIF fails over to a port on the home node or SFO partner only.
- broadcast-domain-wide - The LIF fails over to a port in the same broadcast domain as the home port.
- disabled - Failover is disabled for the LIF.

Note: The failover policy for cluster logical interfaces is local-only and cannot be changed. The default failover policy for data logical interfaces is system-defined. This value can be changed.

Note: Logical interfaces for SAN protocols do not support failover. Thus, such interfaces always show this parameter as disabled.

Use this parameter to set the firewall policy for the LIF. A LIF can use a default firewall policy that corresponds to its role (management, cluster, or data) or a custom firewall policy created by an administrator. When using a custom policy, the interface will fallback on its role’s default policy for unspecified services.
View existing firewall policies with the "system services firewall policy show" command. Modify existing firewall policies with the "system services firewall policy modify" command.

`[-auto-revert {true|false}] - Auto Revert`

Use this parameter to modify whether a data LIF is reverted automatically to its home node under certain circumstances. These circumstances would include startup, when the status of the management database changes to either master or secondary, and when the network connection is made. The default setting is false. If you set the value of this parameter to true, the load balancing migration capability of the data LIF is disabled (the `-allow-lb-migrate` parameter is set to false).

**Note:** Logical interfaces for SAN traffic do not support auto-revert. Thus, this parameter is always false on such interfaces.

`[-dns-zone {<zone-name>|none}] - Fully Qualified DNS Zone Name`

Use this parameter to modify the unique, fully qualified domain name of the DNS zone to which this data LIF belongs. You can associate a data LIF with a single DNS zone. All data LIFs included in a zone must be on the same Vserver. If you do not specify a value for this parameter, the data LIF is created with the value none.

`[-listen-for-dns-query {true|false}] - DNS Query Listen Enable`

Use this parameter to specify if the LIF has to listen for DNS queries. The default value for this parameter is true.

`[-allow-lb-migrate {true|false}] - (DEPRECATED)-Load Balancing Migrate Allowed (privilege: advanced)`

**Note:** This parameter has been deprecated and may be removed in a future version of Data ONTAP.

Use this parameter to modify whether or not load balancing migration is enabled for this data LIF. The default value of this parameter is false. If you set the value of this parameter to true, the automatic revert capability of the data LIF is disabled (the `-auto-revert` parameter is set to false). Also, data LIFs that migrate as a result of load balancing adhere to network interface failover rules.

**Note:** During times when a LIF is hosting active NFSv4, CIFS, or NRV connections, load balancing based LIF migrations between nodes will be temporarily disabled.

`[-lb-weight {load|0..100}] - Load Balanced Weight (privilege: advanced)`

Use this parameter to modify the load balancing weight of the data LIF. A valid load balancing weight is any integer between 1 and 100. If you specify the same load balancing weight for all data LIFs in a DNS zone, client requests are uniformly distributed, similar to round-robin DNS. A data LIF with a low load balancing weight is made available for client requests less frequently than one that has a high load balancing weight.

`[-failover-group <failover-group>] - Failover Group Name`

Use this parameter to modify the name of the failover group to associate with the network interface. Manage failover groups using the `network interface failover-groups` command. Each broadcast domain has a default failover group which is created by the system automatically and has the same name as the broadcast domain. The failover group associated with the broadcast domain includes all ports in the broadcast domain. A logical interface's failover group is set to the failover group of the home port's broadcast domain by default, but this value can be modified.

**Note:** Logical interfaces for SAN protocols do not support failover. Thus, this parameter cannot be specified for such interfaces.

`[-comment <text>] - Comment`

Use this parameter to modify the comment associated with the LIF.

`[-force-subnet-association {true}] - Force the LIF's Subnet Association`

This command will fail if the IP address falls within the address range of a named subnet. Set this to true to acquire the address from the named subnet and assign the subnet to the LIF.
[-is-dns-update-enabled \(true|false\)] - Is Dynamic DNS Update Enabled?

If this parameter is set to \(true\), then dynamic DNS update is sent to the DNS server for the particular LIF entry if dynamic DNS updates are enabled for the corresponding Vserver. This field is set to \(true\) by default for both IPv4 and IPv6 LIFs. DNS Update is not supported on LIFs not configured with either the NFS or CIFS protocol.

Examples
The following example modifies a LIF named datalif1 on a logical server named vs0. The LIF's netmask is modified to 255.255.255.128.

```
cluster1::> network interface modify -vserver vs0 -lif datalif1 -netmask 255.255.255.128
```

**network interface rename**

Rename a logical interface

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**
Use the network interface rename command to change the name of an existing logical interface.

**Parameters**
- `vserver <vserver>` - Vserver Name
  
  Use this parameter to specify the Vserver on which the logical interface to rename is located.

- `lif <lif-name>` - Logical Interface Name
  
  Use this parameter to specify the name of the logical interface to rename.

- `newname <text>` - The new name for the interface
  
  Use this parameter to specify the new name of the logical interface. For iSCSI and FC LIFs, the name cannot be more than 254 characters.

**Examples**
The following example renames a cluster logical interface named cluslif1 to cluslif4 on a Vserver named vs0.

```
cluster1::> network interface rename -vserver vs0 -lif cluslif1 -newname cluslif4
```

**network interface revert**

Revert a logical interface to its home port

**Availability:** This command is available to cluster administrators at the admin privilege level.
**Description**

The `network interface revert` command reverts a logical interface that is not currently on its home port to its home port, assuming that the home node and port are both operational. A logical interface's home port is specified when the logical interface is created. Determine a logical interface's home port by using the `network interface show` command.

**Note:** When you revert a cluster logical interface, you must do so from the local node.

**Note:** On some cloud platforms, this operation might perform changes to the external route tables.

**Parameters**

- `-vserver <vserver>` - Vserver Name
  
  Use this parameter to specify the Vserver on which the logical interface to be reverted is located.

- `-lif <lif-name>` - Logical Interface Name
  
  Use this parameter to specify the logical interface that is to be reverted.

  **Note:** Logical interfaces for SAN protocols are always home. Thus, this command has no effect on such interfaces. The same applies to logical interfaces for NAS protocols that are already home.

**Examples**

The following example returns any logical interfaces that are not currently on their home ports to their home ports.

```bash
cluster1::> network interface revert -vserver * -lif *
```

**Related references**

`network interface show` on page 344

**network interface show**

Display logical interfaces

**Availability:** This command is available to cluster and Vserver administrators at the `admin` privilege level.

**Description**

The `network interface show` command displays information about logical interfaces.

Running the command with the `-failover` parameter displays information relevant to logical interface failover rules.

Running the command with the `-status` parameter displays information relevant to logical interface operational status.

Running the command with the `-by-ipspace` parameter displays information relevant to logical interfaces on a specific IPspace.

See the examples for more information.

You can specify additional parameters to display only information that matches those parameters. For example, to display information only about logical interfaces whose operational status is down, run the command with the `-status-oper down` parameter.

**Parameters**

- `[-fields <fieldname>, ...]`
  
  If you specify the `-fields <fieldname>, ...` parameter, the command displays only the fields that you specify.

- `[-by-ipspace]`
  
  Use this parameter to display logical-interfaces sorted by IPspace and Vserver.
Use this parameter to display logical-interfaces and whether the interface is associated with a Domain Name System (DNS) load balancing zone.

Use this parameter to display logical-interface failover information.

Use this parameter to display detailed logical-interface status information.

Use this parameter to display all the fields for the specified logical-interfaces.

Use this parameter to display information only about logical interfaces on the Vserver you specify.

Use this parameter plus the -lif parameter to display detailed information only about the logical interface you specify.

Use this parameter to display information only about logical interfaces that match the name you specify.

Use this parameter with the -vserver parameter to display detailed information only about the logical interface you specify.

Use this parameter to display information only about logical interfaces that have the service policy you specify.

Use this parameter to display information only about logical interfaces that support all services in a comma-separated list of service names.

Use this parameter to display information only about logical interfaces that are associated with network ports that have the role you specify.

Use this parameter to display information only about logical interfaces that have the enabled data protocols you specify.

Use this parameter to display information only about logical interfaces that have the enabled data protocols you specify.

Use this parameter to display information only about logical interfaces that match the IP address or address range you specify.

Use this parameter to display information only about logical interfaces that have the netmask you specify.

Use this parameter to display information only about logical interfaces with a netmask that has the number of bits you specify.

Use this parameter to display information only about logical interfaces that are VIP LIFs or not as you specify.

Use this parameter to display the logical interfaces that match the subnet name.
[\texttt{-home-node \textless nodename\textgreater}] - Home Node

Use this parameter to display information only about logical interfaces that have the home node you specify.

[\texttt{-home-port \{\textless netport\}|\textless ifgrp\textgreater}] - Home Port

Use this parameter to display information only about logical interfaces that have the home port or interface group you specify.

[\texttt{-curr-node \textless nodename\textgreater}] - Current Node

Use this parameter to display information only about logical interfaces that are currently located on the node you specify.

[\texttt{-curr-port \{\textless netport\}|\textless ifgrp\textgreater}] - Current Port

Use this parameter to display information only about logical interfaces that are currently located on the port or interface group you specify.

[\texttt{-status-oper \{up\}|\textless down\textgreater}] - Operational Status

Use this parameter to display information only about logical interfaces that have the operational status you specify.

[\texttt{-status-extended \textless text\textgreater}] - Extended Status

Use this parameter to display information only about logical interfaces that match the extended status that you specify.

[\texttt{-numeric-id \textless integer\textgreater}] - Numeric ID (privilege: advanced)

Use this parameter to display information only about logical interfaces with the numeric ID (or range of IDs) you specify. The numeric ID is an integer that identifies the logical interface in the cluster.

[\texttt{-is-home \{true\}|\textless false\textgreater}] - Is Home

Use this parameter to display information only about logical interfaces that are (true) or are not (false) currently located on their home node and port.

[\texttt{-status-admin \{up\}|\textless down\textgreater}] - Administrative Status

Use this parameter to display information only about logical interfaces that have the administrative status you specify.

[\texttt{-failover-policy \{system-defined\}|\textless local-only\textgreater|\textless sfo-partner-only\textgreater|\textless disabled\textgreater|\textless broadcast-domain-wide\textgreater}] - Failover Policy

Use this parameter to display information only about logical interfaces that use the failover policy you specify.

[\texttt{-firewall-policy \textless policy\textgreater}] - Firewall Policy

Use this parameter to display information only about logical interfaces that use the firewall policies you specify.

[\texttt{-auto-revert \{true\}|\textless false\textgreater}] - Auto Revert

Use this parameter to display information only about logical interfaces that have auto-revert setting you specify.

[\texttt{-sticky \{true\}|\textless false\textgreater}] - Sticky Flag (privilege: advanced)

Use this parameter to display information only about logical interfaces that are "sticky". A sticky logical interface is one that has been manually migrated to another node and is not subject to auto-revert settings. A sticky logical interface remains at the migrated location until it is manually reverted or until it fails over to another node.

[\texttt{-dns-zone \{\textless zone-name\}|\textless none\textgreater}] - Fully Qualified DNS Zone Name

Use this parameter to display information only about logical interfaces in the specified DNS zone.

[\texttt{-listen-for-dns-query \{true\}|\textless false\textgreater}] - DNS Query Listen Enable

Use this parameter to display information only about logical interfaces that have the DNS query listen value you specify.
[-allow-lb-migrate \(\{true|false\}\)] - (DEPRECATED)-Load Balancing Migrate Allowed (privilege: advanced)

**Note:** This parameter has been deprecated and may be removed in a future version of Data ONTAP.
Use this parameter to display information only about logical interfaces for which load balancing migration is activated (true) or not activated (false).

[-lb-weight \(load\{0..100\}\)] - Load Balanced Weight (privilege: advanced)

Use this parameter to display information only about logical interfaces that have the load balancing weight you specify.

[-failover-group <failover-group>] - Failover Group Name

Use this parameter to display information only about logical interfaces that are in the failover group you specify. Logical interfaces in the same failover group are capable of failing over to the same set of ports.

[-wwpn <text>] - FCP WWPN

Use this parameter to display information only about logical interfaces that have the Fibre Channel Protocol port identifier (World Wide Port Name) you specify.

[-address-family \(ipv4|ipv6|ipv6z\)] - Address family

Use this parameter to view the address family that is in use on the interface. Only IPv4 and IPv6 non-zoned addresses can be configured. Configuration of IPv6z addresses is not allowed.

[-comment <text>] - Comment

Use this parameter to display information only about logical interfaces that have the comment you specify.

[-ipspace <IPspace>] - IPspace of LIF

Use this parameter to display information only about logical interfaces on the IPspace you specify.

[-is-dns-update-enabled \(\{true|false\}\)] - Is Dynamic DNS Update Enabled?

Use this parameter to display information only about logical interfaces that have (true) or do not have (false) dynamic DNS updates enabled for them.

[-probe-port <integer>] - Probe-port for Azure ILB

Use this parameter display the probe-port for the logical interface in the Azure environment.

### Examples

The following example displays general information about all logical interfaces.

```bash
cluster1::> network interface show
Logical  Status     Network            Current       Current Is
Interface Admin/Oper Address/Mask       Node          Port    Home
----------- ---------- ------------------ ------------- ------- ----
cluster1
cluster_mgmt
up/up      192.0.2.1/192      node0         e0M     true
node0_mgmt1
up/up      192.0.2.2/192      node0         e0M     true
node1_mgmt1
up/up      192.0.2.3/192      node1         e0M     true
Cluster
node0_clus1
up/up      192.0.2.66/192     node0         e0a     true
node0_clus2
up/up      192.0.2.67/192     node0         e0b     true
node1_clus1
up/up      192.0.2.68/192     node1         e0a     true
node1_clus2
up/up      192.0.2.69/192     node1         e0b     true
```

The following example displays failover information about all logical interfaces.
network interface start-cluster-check

Start the cluster check function

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
The network interface start-cluster-check command initiates an accessibility check from every logical interface to every aggregate. Automatic checks run periodically, but this command manually initiates a check immediately.

This command produces no direct output. Any errors encountered during the check are reported in the event log. See the event log show command for more information.

Examples
This example shows an execution of this command, with all parameters and output.

```
cluster1::> network interface start-cluster-check
```

Related references

event log show on page 116

network interface capacity commands

The capacity directory
network interface capacity show

Display the number of IP data LIFs capable of being configured on the cluster.

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**
The network interface capacity show command displays the number of IP LIFs of role data supported on the cluster, as well as the number of IP LIFs of role data currently configured on the cluster.

**Note:** The number of IP LIFs of role data that are supported on a node depends on the hardware platform and the Cluster’s Data ONTAP version. If one or more nodes in the cluster cannot support additional LIFs, then none of the nodes in the cluster can support additional LIFs.

**Examples**
The following displays the IP data LIF capacity.

```
cluster1::> network interface capacity show
<table>
<thead>
<tr>
<th>IP Data LIF</th>
<th>IP Data LIF</th>
</tr>
</thead>
<tbody>
<tr>
<td>Supported Limit</td>
<td>Count</td>
</tr>
<tr>

network interface capacity details commands

The details directory

network interface capacity details show

Display details about the IP data LIFs capable of being configured on each node.

**Availability:** This command is available to cluster administrators at the advanced privilege level.

**Description**
The network interface capacity details show command displays the number of IP LIFs of role data that can be configured on each node, the number of IP data LIFs of role data that are supported on each node, and the number of IP data LIFs of role data that are configured to be homed on each node.

**Note:** The number of IP LIFs of role data that are supported on a node depends on the hardware platform and the Cluster’s Data ONTAP version. If one or more nodes in the cluster cannot support additional LIFs, then none of the nodes in the cluster can support additional LIFs.

**Parameters**

```
[-fields <fieldname>, ...]
```

If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use ‘-fields ?’ to display the fields to specify.

```
[-instance ]
```

If you specify the -instance parameter, the command displays detailed information about all fields.

```
[-node (<nodename> | local)] - Node Name
```

Use this parameter to specify the node for which to obtain data LIF capacity.
[[-capacity-for-node <integer>]] - Number of IP data LIFs that can be configured on the node

This parameter specifies the number of IP LIFs of role data that can be configured on the node at the currently running Data ONTAP version. To view the version of a node, use the `cluster image show` command.

[[-limit-for-node <integer>]] - Number of IP data LIFs that are supported on the node

This parameter specifies the number of IP LIFs of role data that are supported on the node at the current effective cluster version (ECV). To view the version of a node, use the `cluster image show` command.

[[-count-for-node <integer>]] - Number of IP data LIFs that are assigned to the node

This parameter specifies the number of IP LIFs of role data currently configured to be homed on the node. To view LIFs homed on this node, use the `network interface show -home-node` command.

### Examples

The following displays the IP data LIF capacity.

```
cluster1::> network interface capacity details show
IP Data LIF       IP Data LIF      IP Data LIF
Node        Capacity   Supported Limit            Count
-----------------  ---------------  ---------------  ---------------
node1              512              512              128
node2              512              512              128
```

**network interface check failover commands**

The failover directory

**network interface check failover show**

Discover if any LIFs might become inaccessible during a node outage, due to over-provisioning

**Availability:** This command is available to `cluster` administrators at the `admin` privilege level.

**Description**

This command identifies logical interfaces (LIFs) at risk of becoming inaccessible if their hosting nodes were to experience an outage. The source-nodes parameter is the only required input.

The tuple `<destination-nodes, vserver-name, lif-name>` is sufficient to uniquely identify a record in the returned listing. All fields other than source-nodes can be filtered on in the usual fashion. There are some examples of this filtering below.

**Parameters**

Optionally:

<table>
<thead>
<tr>
<th>[-fields &lt;fieldname&gt;, ...]</th>
</tr>
</thead>
<tbody>
<tr>
<td>If you specify the <code>-fields &lt;fieldname&gt;, ...</code> parameter, the command output also includes the specified field or fields. You can use <code>-fields ?</code> to display the fields to specify.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>[-instance]</th>
</tr>
</thead>
<tbody>
<tr>
<td>If you specify the <code>-instance</code> parameter, the command displays detailed information about all fields.</td>
</tr>
</tbody>
</table>
[-destination-nodes <nodename>, ...] - Set Of Nodes Over Capacity
Use this parameter to display the nodes an at-risk LIF or LIFs could fail over to.

[-vserver-name <vserver>] - Vserver Name
Use this parameter to display only LIFs on the Vserver you specify.

[-lif-name <lif-name>] - LIF Name
Use this parameter to display at-risk information only about the LIF or LIFs whose name you specify.

-source-nodes <nodename>, ... - Nodes Going Down
List of nodes to test. At-risk LIFs currently hosted on these nodes will be identified. The list should contain no more than half the nodes in the cluster.

[-over-amount <integer>] - Amount Capacity Exceeded
Use this parameter to select only at-risk LIFs associated with a set of destination nodes whose amount over capacity matches the number you specify.

Note that the number of LIFs considered to be at risk may be higher than the actual amount over capacity a given set of nodes is. Once a given set of nodes is determined to be potentially over capacity, all LIFs whose set of failover target nodes is an exact match are marked as at risk. The amount over capacity is an upper bound on the number LIFs which could become unhosted if LIFs were to fail over in a random order, each to a target randomly selected from that LIF’s configured failover targets.

[-failover-group <failover-group>] - Failover Group Name
Use this parameter to display information only about at-risk LIFs whose failover-group you specify.

[-failover-policy {system-defined|local-only|sfo-partner-only|disabled|broadcast-domain-wide}] - Failover Policy
Use this parameter to display information only about at-risk LIFs whose failover-policy you specify.

Examples
The following example shows all the at-risk LIFs for a specific two-node outage in a six-node cluster.

```
cluster1::> network interface check failover show -source-nodes node1,node5
Destination Nodes: node2, node3, node4, node6
Amount Over Capacity: 2
Vserver Logical Interface Failover Group Failover Policy
------------------ ------------------- ---------------- ---------------------
vs0 data1 Default broadcast-domain-wide
     data2 Default broadcast-domain-wide
     data3 Default broadcast-domain-wide
vs1 data1 Custom_Name broadcast-domain-wide

Destination Nodes: node2
Amount Over Capacity: 1
Vserver Logical Interface Failover Group Failover Policy
------------------ ------------------- ---------------- ---------------------
vs0 data6 Default sfo-partner-only
vs1 data7 Default sfo-partner-only
```

The following example shows the same two-node outage scenario, but now with some filtering applied to the results.

```
cluster1::> network interface check failover show -source-nodes node1,node5 -destination-nodes node2,node3,node4,node6 -failover-group Def*
Destination Nodes: node2, node3, node4, node6
Amount Over Capacity: 2
Vserver Logical Interface Failover Group Failover Policy
------------------ ------------------- ---------------- ---------------------
```
network interface failover-groups commands

Manage logical interface failover group configuration

network interface failover-groups add-targets

Add failover targets to a failover group

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The network interface failover-groups add-targets command enables you to add a list of failover targets such as network ports, interface groups, or VLANs to an existing logical interface failover group.

Parameters
-\texttt{-vserver <vserver>\textbf{- Vserver Name\textquoteleft\textquoteleft}}
  Use this parameter to specify the name of the Vservers from which this failover group is accessible.

-\texttt{-failover-group <text>\textbf{- Failover Group Name\textquoteleft\textquoteleft}}
  Use this parameter to specify the failover group that you want to extend.

-\texttt{-targets <<node>:<port>>, ...\textbf{- Failover Targets\textquoteleft\textquoteleft}}
  Use this parameter to specify the failover targets such as network ports, interface groups, or VLANs you wish to add to the failover group.

Examples
This example shows the failover group "clyde" being extended to include additional failover targets.

\begin{verbatim}
cluster1::> network interface failover-group add-targets -vserver vs1 -failover-group clyde -targets xenal1:e0c, xenal1:e0d-100, xena2:a0a
\end{verbatim}

network interface failover-groups create

Create a new failover group

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The network interface failover-groups create command creates a grouping of failover targets for logical interfaces on one or more nodes. Use this command to add a new network port or interface group to an existing failover group.

Note: Interfaces for SAN protocols do not support failover. Such interfaces are not valid failover targets.

Parameters
-\texttt{-vserver <vserver>\textbf{- Vserver Name\textquoteleft\textquoteleft}}
  Use this parameter to specify the name of the Vservers from which this failover group is accessible.

-\texttt{-failover-group <text>\textbf{- Failover Group Name\textquoteleft\textquoteleft}}
  Use this parameter to specify the name of the logical interface failover group that you want to create.
-targets <<node>:<port>>, ... - Failover Targets

Use this parameter to specify the list of failover targets (network ports, interface groups, or VLANs on a node) belonging to this failover group.

Examples
The following example shows how to create a failover group named failover-group_2 containing ports e1e and e2e on node Xena.

```
cluster1::> network interface failover-groups create -vserver vs0 -failover-group failover-group_2
    -targets xena:e1e,xena:e2e
```

network interface failover-groups delete

Delete a failover group

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The `network interface failover-groups delete` command deletes a logical interface failover group.

Parameters
- `vserver <vserver>` - Vserver Name
  Use this parameter to specify the name of the Vservers from which this failover group is accessible.

- `failover-group <text>` - Failover Group Name
  Use this parameter to specify the name of the logical interface failover group to be deleted.

Examples
The following example shows how to delete a failover group named failover-group_2.

```
cluster1::> network interface failover-groups delete -vserver vs1 -failover-group failover-group_2
```

network interface failover-groups modify

Modify a failover group

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The `network interface failover-groups modify` command enables you modify the list of network ports, interface groups, or VLANs belonging to an existing logical interface failover group. The specified list will overwrite the existing list of network ports, interface groups, and VLANs currently belonging to the logical interface failover group.

Parameters
- `vserver <vserver>` - Vserver Name
  Use this parameter to specify the name of the Vserver(s) from which this failover group is accessible.

- `failover-group <text>` - Failover Group Name
  Use this parameter to specify the failover group that you want to modify.

- `[-targets <<node>:<port>>, ...]` - Failover Targets
  Use this parameter to specify the network ports, interface groups, or VLANs you wish to now belong to the failover group.
Examples
This example shows the failover group "clyde" being modified to now contain the specified network ports.

```
cluster1::> network interface failover-group modify -vserver vs1 -failover-group clyde -targets xena1:e0c, xena1:e0d-100, xena2:a0a
```

**network interface failover-groups remove-targets**

Remove failover targets from a failover group

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**
The `network interface failover-groups remove-targets` command enables you to specify a list of failover targets such as network ports, interface groups, or VLANs to be removed from an existing logical interface failover group.

**Parameters**
- `-vserver <vserver>` - Vserver Name
  
  Use this parameter to specify the name of the Vserver(s) from which this failover group is accessible.

- `-failover-group <text>` - Failover Group Name
  
  Use this parameter to specify the failover group that you want to remove failover targets from.

- `-targets <<node>:<port>>, ...` - Failover Targets
  
  Use this parameter to specify the failover targets such as network ports, interface groups, or VLANs you wish to remove from the failover group.

Examples
This example shows the failover targets xena1:e0c and xena1:e0d-100 being removed from the failover group "clyde".

```
cluster1::> network interface failover-group remove-targets -vserver vs1 -failover-group clyde -targets xena1:e0c, xena1:e0d-100, xena2:a0a
```

**network interface failover-groups rename**

Rename a logical interface failover Group

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**
The `network interface failover-groups rename` command enables you to rename an existing logical interface failover group.

**Parameters**
- `-vserver <vserver>` - Vserver Name
  
  Use this parameter to specify the name of the Vservers from which this failover group is accessible.

- `-failover-group <text>` - Failover Group Name
  
  Use this parameter to specify the failover group that you want to rename.

- `-new-failover-group-name <text>` - New name
  
  Use this parameter to specify the new name of the failover group.
Examples
This example shows the failover group "clusterwide" being renamed "clyde".

```
cluster1::> network interface failover-group rename -failover -vserver vs1 -failover-group clusterwide -new-failover-group-name clyde
```

**network interface failover-groups show**

Display logical interface failover groups

**Availability:** This command is available to cluster and Vserver administrators at the admin privilege level.

**Description**
The `network interface failover-groups show` command displays information about logical interface failover groups.

**Parameters**

- `[-fields <fieldname>, ...]`
  
  If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

- `[-instance]`
  
  If you specify the `-instance` parameter, the command displays detailed information about all fields.

- `[-vserver <vserver>] - Vserver Name`
  Use this parameter to display information only about the logical interface failover groups that have the target Vserver you specify.

- `[-failover-group <text>] - Failover Group Name`
  Use this parameter to display information only about the logical interface failover groups you specify.

- `[-targets <<node>:<port>>, ...] - Failover Targets`
  Use this parameter to display information only about the logical interface failover groups that have the failover target (physical port, interface group, or VLAN) you specify.

- `[-broadcast-domain <Broadcast Domain>] - Broadcast Domain`
  Use this parameter to display information only about the logical interface failover groups that have the broadcast domain you specify.

**Examples**
The following example displays information about all logical interface failover groups on a two node cluster.

```
cluster1::> network interface failover-groups show

<table>
<thead>
<tr>
<th>Vserver</th>
<th>Group</th>
<th>Targets</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cluster</td>
<td>Cluster</td>
<td>node1:e1a, node1:e2a, node2:e1a, node2:e2a,</td>
</tr>
<tr>
<td>cluster1</td>
<td>Default</td>
<td>node1:e0M, node1:e0a, node1:e0b, node1:e0c, node1:e0d, node2:e0M, node2:e0a, node2:e0b, node2:e0c, node2:e0d</td>
</tr>
</tbody>
</table>
```
network interface dns-lb-stats commands

The dns-lb-stats directory

network interface dns-lb-stats show

Show the DNS load-balancer stats for this node

Availability: This command is available to cluster and Vserver administrators at the advanced privilege level.

Description
The network interface dns-lb-stats show command displays the statistics for DNS load-balancing lookups for the zones belonging to the specified Vserver. These statistics represent the data for the Vserver on the local node. The following counts can be seen in the statistics output:

- success-count : Number of successful lookups.
- authoritative-count : Number of authoritative answers sent.
- nonauthoritative-count : Number of non authoritative answers sent.
- rr-set-missing-count : Number of times the RR set was missing.
- domain-missing-count : Number of times the domain was not be found.
- failure-count : Number of failed lookups.
- dropped-count : Number of lookups dropped.

Parameters

[[-fields <fieldname>, ...]
  If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

| [-instance ]
  If you specify the -instance parameter, the command displays detailed information about all fields.

[-vserver <vserver>] - Vserver
  Use this parameter to display DNS load-balancer statistics only for the specified Vservers.

[-zone <text>] - DNS Zone
  Use this parameter to display DNS load-balancer statistics only for the specified DNS zones.

[-success-count <integer>] - Successful Lookup Count
  Use this parameter to display DNS load-balancer statistics only for the specified number of successful lookups.

[-authoritative-count <integer>] - Authoritative Answer Count
  Use this parameter to display DNS load-balancer statistics only for the specified number of authoritative answers sent.

[-nonauthoritative-count <integer>] - Non Authoritative Answer Count
  Use this parameter to display DNS load-balancer statistics only for the specified number of non-authoritative answers sent.

[-rr-set-missing-count <integer>] - RR Set Missing Count
  Use this parameter to display DNS load-balancer statistics only for the specified number of times the RR set was missing.
[-domain-missing-count <integer>] - Name Missing Count
   Use this parameter to display DNS load-balancer statistics only for the specified number of times the domain was not found.

[-failure-count <integer>] - Failed Lookup Count
   Use this parameter to display DNS load-balancer statistics only for the specified number of failed lookups.

[-dropped-count <integer>] - Dropped Count
   Use this parameter to display DNS load-balancer statistics only for the specified number of dropped lookups.

Examples
The following example displays stats for the zone "x.com".

```
cluster1::> network interface dns-lb-stats show -zone x.com
Vserver    DNS Zone           SUCCESS    AUTH  NOAUTH  NORR  NODOM  FAILED  DROP
---------  -----------------  -------   -----  ------ -----  -----  ------ -----
        vs2                x.com            5       5       0     0      0       0     0
```

network interface lif-weights commands
The lif-weights directory

network interface lif-weights show
Show the load-balancer LIF weights

Availability: This command is available to cluster and Vserver administrators at the advanced privilege level.

Description
The network interface lif-weights show command displays the weights assigned to each LIF in a DNS load-balancing zone in a Vserver.

Parameters
{ [-fields <fieldname>, ...] 
   If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use ‘-fields ?’ to display the fields to specify.

| [-instance ]] 
   If you specify the -instance parameter, the command displays detailed information about all fields.

[-vserver <vserver>] - Vserver
   Use this parameter to display information only for the specified Vservers.

[-zone <text>] - DNS Zone
   Use this parameter to display information only for the specified DNS zones.

[-address <IP Address>] - Network Address
   Use this parameter to display information only for the specified IP addresses.

[-weight <double>] - Load Balancer Weight
   Use this parameter to display information only for the specified load balancer weights

Examples
The following example displays LIF weights for vserver "vs1". 
network interface service-policy commands

The service-policy directory

database interface service-policy add-service

Add an additional service entry to an existing service policy

Availability: This command is available to cluster administrators at the advanced privilege level.

Description

The network interface service-policy add-service command adds an additional service to an existing service-policy. When an allowed address list is specified, the list applies to only the service being added. Existing services included in this policy are not impacted.

Parameters

- `-vserver <vserver name> - Vserver`
  Use this parameter to specify the name of the Vserver of the service policy to be updated.

- `-policy <text> - Policy Name`
  Use this parameter to specify the name of service policy to be updated.

- `-service <LIF Service Name> - Service entry to be added`
  Use this parameter to specify the name of service to be added to the existing service policy.

- `[-allowed-addresses <IP Address/Mask>, ...] - Allowed address ranges for the service`
  Use this parameter to specify a list of subnet masks for addresses that are allowed to access this service. Use the value `0.0.0.0/0` to represent the wildcard IPv4 address and `::/0` to represent the wildcard IPv6 address.

Examples

The following example shows the addition of a service to an existing service policy.

```
cluster1::> network interface service-policy show -vserver cluster1
Vaerker  Policy                     Service: Allowed Addresses
--------- -------------------------- ----------------------------------------
cluster1
default-intercluster       intercluster-core: 0.0.0.0/0
                             management-https: 0.0.0.0/0

default-management       management-core: 0.0.0.0/0
                             management-autosupport: 0.0.0.0/0
                             management-ssh: 0.0.0.0/0
                             management-https: 0.0.0.0/0

default-route-announce     management-bgp: 0.0.0.0/0

3 entries were displayed.
```

```
cluster1::> network interface service-policy add-service -vserver cluster1 -policy default-intercluster -service management-ssh
cluster1::> network interface service-policy show -vserver cluster1
```
network interface service-policy clone

Clone an existing network service policy

**Availability:** This command is available to cluster administrators at the *advanced* privilege level.

**Description**
The `network interface service-policy clone` command creates a new service policy that includes the same services and allowed addresses as an existing policy. Once the new service policy has been created, it can be modified as necessary without impacting the original policy.

**Parameters**

- `-vserver <vserver name>` - *Vserver*
  
  Use this parameter to specify the name of the Vserver of the service policy to be cloned.

- `-policy <text>` - *Policy Name*
  
  Use this parameter to specify the name of the service policy to be cloned.

- `-target-vserver <vserver name>` - *Vserver Name*
  
  Use this parameter to specify the name of the vserver on which the new service policy should be created.

- `-target-policy <text>` - *New Service Policy Name*
  
  Use this parameter to specify the name of the new service policy.

**Examples**
The following example shows the cloning of a service policy.
The network interface service-policy create command creates a new service policy with a list of included services. LIFs can reference this policy to control the list of services that they are able to transport on their network. Services can represent applications accessed by a LIF as well as applications served by this cluster.

**Parameters**

- **-vserver <vserver name>** - Vserver
  
  Use this parameter to specify the name of the Vserver on which the service policy will be created.

- **-policy <text>** - Policy Name
  
  Use this parameter to specify the name of service policy to be created.

- **[-services <LIF Service Name>, ...]** - Included Services
  
  Use this parameter to specify a list of services that should be included in this policy.
[-allowed-addresses <IP Address/Mask>, ...] - Allowed Addresses

Use this parameter to specify a list of subnet masks for addresses that are allowed to access the services in this policy. Use the value 0.0.0.0/0 to represent the wildcard IPv4 address and ::/0 to represent the wildcard IPv6 address.

Examples

The following example shows the creation of a service policy with no initial services.

```
cluster1::> network interface service-policy create -vserver cluster1 -policy empty
cluster1::> network interface service-policy show -vserver cluster1
```

<table>
<thead>
<tr>
<th>Vserver</th>
<th>Policy</th>
<th>Service: Allowed Addresses</th>
</tr>
</thead>
<tbody>
<tr>
<td>cluster1</td>
<td>default-intercluster</td>
<td>intercluster-core: 0.0.0.0/0</td>
</tr>

5 entries were displayed.

**network interface service-policy delete**

Delete an existing service policy

**Availability:** This command is available to cluster administrators at the advanced privilege level.

**Description**

The `network interface service-policy delete` command deletes an existing service policy.
Parameters

- **vserver** `<vserver name>` - **Vserver**
  
  Use this parameter to specify the name of the Vserver of the service policy to be deleted.

- **policy** `<text>` - **Policy Name**
  
  Use this parameter to specify the name of the service policy to be deleted.

Examples

The following example shows the deletion of a service policy.

```
cluster1::> network interface service-policy show -vserver cluster1
Vserver   Policy                     Service: Allowed Addresses
--------- -------------------------- ----------------------------------------
cluster1  custom                     intercluster-core: 0.0.0.0/0
                     management-ssh: 0.0.0.0/0
                     management-https: 0.0.0.0/0
default-intercluster intercluster-core: 0.0.0.0/0
                     management-https: 0.0.0.0/0
default-management  management-core: 0.0.0.0/0
                     management-autosupport: 0.0.0.0/0
                     management-ssh: 0.0.0.0/0
                     management-https: 0.0.0.0/0
default-route-announce management-bgp: 0.0.0.0/0
4 entries were displayed.
```

```
cluster1::> network interface service-policy delete -vserver cluster1 -policy custom
```

```
cluster1::> network interface service-policy show -vserver cluster1
Vserver   Policy                     Service: Allowed Addresses
--------- -------------------------- ----------------------------------------
cluster1  default-intercluster      intercluster-core: 0.0.0.0/0
                     management-https: 0.0.0.0/0
default-management  management-core: 0.0.0.0/0

```

`network interface service-policy modify-service`

Modify a service entry in an existing service policy

**Availability:** This command is available to cluster administrators at the `advanced` privilege level.

**Description**

The `network interface service-policy modify-service` command modifies the policy-specific attributes of a service that is already included in a particular service policy. Other services in the policy are not impacted by the change.

**Parameters**

- **vserver** `<vserver name>` - **Vserver**
  
  Use this parameter to specify the name of the Vserver of the service policy to be updated.
-policy <text> - Policy Name

Use this parameter to specify the name of service policy to be updated.

-service <LIF Service Name> - Service entry to be modified

Use this parameter to specify the name of service to be updated.

-allowed-addresses <IP Address/Mask>,... - Allowed address ranges for the service

Use this parameter to specify a list of subnet masks for addresses that are allowed to access this service. Use the value 0.0.0.0/0 to represent the wildcard IPv4 address and ::/0 to represent the wildcard IPv6 address.

### Examples

The following example shows the modification of a service on an existing service policy.

```
cluster1::> network interface service-policy show -vserver cluster1
Vserver   Policy                     Service: Allowed Addresses
--------- -------------------------- ----------------------------------------
cluster1  default-intercluster       intercluster-core: 0.0.0.0/0
management-https: 0.0.0.0/0

default-management
management-core: 0.0.0.0/0
management-autosupport: 0.0.0.0/0
management-ssh: 0.0.0.0/0
management-https: 0.0.0.0/0

default-route-announce
management-bgp: 0.0.0.0/0

3 entries were displayed.

cluster1::> network interface service-policy modify-service -vserver cluster1 -policy default-management -service management-ssh -allowed-addresses 10.1.0.0/16

cluster1::> network interface service-policy show -vserver cluster1
Vserver   Policy                     Service: Allowed Addresses
--------- -------------------------- ----------------------------------------
cluster1  default-intercluster       intercluster-core: 0.0.0.0/0
management-https: 0.0.0.0/0

default-management
management-core: 0.0.0.0/0
management-autosupport: 0.0.0.0/0
management-ssh: 10.1.0.0/16
management-https: 0.0.0.0/0

default-route-announce
management-bgp: 0.0.0.0/0

3 entries were displayed.
```

network interface service-policy remove-service

Remove a service entry from an existing service policy

**Availability:** This command is available to cluster administrators at the advanced privilege level.

**Description**

The network interface service-policy remove-service command removes an individual service from an existing service policy. Other services in the policy are not impacted by the change.

**Parameters**

-service <service-name> - Service

Use this parameter to specify the name of the service to be removed.

-vserver <vserver name> - Vserver

Use this parameter to specify the name of the Vserver of the service policy to be updated.
-policy <text> - Policy Name

Use this parameter to specify the name of service policy to be updated.

-service <LIF Service Name> - Service entry to be removed

Use this parameter to specify the name of service to be removed from the existing service policy.

### Examples

The following example shows the removal of a service from an existing service policy.

```bash
cluster1::> network interface service-policy show -vserver cluster1
Vserver   Policy                     Service: Allowed Addresses
--------- -------------------------- ----------------------------------------
cluster1
default-intercluster       intercluster-core: 0.0.0.0/0
management-https: 0.0.0.0/0
default-management         management-core: 0.0.0.0/0
management-autosupport: 0.0.0.0/0
management-ssh: 0.0.0.0/0
management-https: 0.0.0.0/0
default-route-announce     management-bgp: 0.0.0.0/0
3 entries were displayed.
cluster1::> network interface service-policy remove-service -vserver cluster1 -policy default-management -service management-autosupport

cluster1::> network interface service-policy show -vserver cluster1
Vserver   Policy                     Service: Allowed Addresses
--------- -------------------------- ----------------------------------------
cluster1
default-intercluster       intercluster-core: 0.0.0.0/0
management-https: 0.0.0.0/0
default-management         management-core: 0.0.0.0/0
management-ssh: 0.0.0.0/0
management-https: 0.0.0.0/0
default-route-announce     management-bgp: 0.0.0.0/0
3 entries were displayed.
```

### network interface service-policy rename

Rename an existing network service policy

**Availability:** This command is available to cluster administrators at the advanced privilege level.

**Description**

The `network interface service-policy rename` command assigns a new name to an existing service policy without disrupting the LIFs using the policy.

**Parameters**

- **-vserver <vserver name> - Vserver**
  
  Use this parameter to specify the name of the Vserver of the service policy to be renamed.

- **-policy <text> - Policy Name**
  
  Use this parameter to specify the name of the service policy to be renamed.

- **-new-name <text> - New Service Policy Name**
  
  Use this parameter to specify the new name for the service policy.
Examples

The following example shows the renaming of a service policy.

```
cluster1::> network interface service-policy show -vserver cluster1
Vserver   Policy                     Service: Allowed Addresses
--------- -------------------------- ----------------------------------------
cluster1  custom                     intercluster-core: 0.0.0.0/0
          management-autosupport: 0.0.0.0/0
          management-ssh: 0.0.0.0/0
          management-https: 0.0.0.0/0
          management-core: 0.0.0.0/0
          management-autosupport: 0.0.0.0/0
          management-ssh: 0.0.0.0/0
          management-https: 0.0.0.0/0
          management-bgp: 0.0.0.0/0

4 entries were displayed.
```

```
cluster1::> network interface service-policy rename -vserver cluster1 -policy custom -new-name system
```

```
cluster1::> network interface service-policy show -vserver cluster1
Vserver   Policy                     Service: Allowed Addresses
--------- -------------------------- ----------------------------------------
cluster1  system                     intercluster-core: 0.0.0.0/0
          management-autosupport: 0.0.0.0/0
          management-ssh: 0.0.0.0/0
          management-https: 0.0.0.0/0
          management-core: 0.0.0.0/0
          management-autosupport: 0.0.0.0/0
          management-ssh: 0.0.0.0/0
          management-https: 0.0.0.0/0
          management-bgp: 0.0.0.0/0

4 entries were displayed.
```

group

```
43. network interface service-policy restore-defaults

Restore default settings to a service policy

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
The network interface service-policy restore-defaults command restores a built-in service-policy to its original state. The default list of services replaces any customizations that have been applied by an administrator. All included services will be updated to use the default allowed address list.

Parameters
-vserver <vserver name> - Vserver

Use this parameter to specify the name of the Vserver of the service policy to be restored.

-policy <text> - Policy Name

Use this parameter to specify the name of the service policy to be restored.
```
Examples
The following example shows the restoration of a service policy's default settings.

```
cluster1::> network interface service-policy show -vserver cluster1
Vserver   Policy                     Service: Allowed Addresses
--------- -------------------------- ----------------------------------------
cluster1  default-intercluster       intercluster-core: 10.1.0.0/16
         management-ssh: 10.1.0.0/16
         management-https: 10.1.0.0/16
         default-management       management-core: 0.0.0.0/0
         management-autosupport: 0.0.0.0/0
         management-ssh: 0.0.0.0/0
         management-https: 0.0.0.0/0
         default-route-announce    management-bgp: 0.0.0.0/0
3 entries were displayed.
cluster1::> network interface service-policy restore-defaults -vserver cluster1 -policy default-intercluster
cluster1::> network interface service-policy show -vserver cluster1
Vserver   Policy                     Service: Allowed Addresses
--------- -------------------------- ----------------------------------------
cluster1  default-intercluster       intercluster-core: 0.0.0.0/0
         management-https: 0.0.0.0/0
         default-management       management-core: 0.0.0.0/0
         management-autosupport: 0.0.0.0/0
         management-ssh: 0.0.0.0/0
         management-https: 0.0.0.0/0
         default-route-announce    management-bgp: 0.0.0.0/0
3 entries were displayed.
```

**network interface service-policy show**

Display existing service policies

**Availability:** This command is available to cluster and Vserver administrators at the admin privilege level.

**Description**
The `network interface service-policy show` command displays existing service policies.

**Parameters**

```
[-fields <fieldname>, ...]  
If you specify the -fields <fieldname>, ... parameter, the command displays only the fields that you specify.

[-instance]  
If you specify the -instance parameter, the command displays detailed information about all fields.

[-vserver <vserver name>] - Vserver  
Selects service policies that match the specified vserver name.

[-policy <text>] - Policy Name  
Selects service policies that match the specified service policy name.
```
[-services <LIF Service Name>, ...] - Included Services
Selects service policies that contain all services in the specified list of service names.

[-service-allowed-addresses <text>, ...] - Service: Allowed Addresses
Selects service policies that contain all "<service>:<allowed-addresses>" in the specified list of addresses.

Examples
The following example displays the built-in service policies.

```
cluster1::> network interface service-policy show -vserver cluster1
Vserver   Policy                     Service: Allowed Addresses
--------- -------------------------- ----------------------------------------
cluster1  default-intercluster       intercluster-core: 0.0.0.0/0
           management-https: 0.0.0.0/0
            default-management         management-core: 0.0.0.0/0
                                       management-autosupport: 0.0.0.0/0
                                       management-ssh: 0.0.0.0/0
                                       management-https: 0.0.0.0/0
            default-route-announce     management-bgp: 0.0.0.0/0
3 entries were displayed.
```

network interface service commands
The service directory

network interface service show
Display available interface services

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The network interface service show command displays available services for IP LIFs and the TCP or UDP ports that each service listens on. The ports listed in this table correspond to well-known ports that each service can be expected to open a listening socket. Services that do not listen for ingress connections are presented with an empty port list.

Parameters

<table>
<thead>
<tr>
<th>[-fields &lt;fieldname&gt;, ...]</th>
</tr>
</thead>
<tbody>
<tr>
<td>If you specify the -fields &lt;fieldname&gt;, ... parameter, the command displays only the fields that you specify.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>[-restrictions] (privilege: advanced)</th>
</tr>
</thead>
<tbody>
<tr>
<td>The network interface service show-restrictions command displays available services for IP LIFs and usage restrictions for each service. The restrictions determine which LIFs are permitted to use each service and what restrictions the service implies for the LIFs that do use it.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>[-instance]</th>
</tr>
</thead>
<tbody>
<tr>
<td>If you specify the -instance parameter, the command displays detailed information about all fields.</td>
</tr>
</tbody>
</table>

[-service <LIF Service Name>] - Service Name
Selects services that match the specified service name.
[-ports <integer>, ...] - TCP/UDP Port Numbers
Selects services that contain all IP ports in the specified list.

[-protocol-ports <text>, ...] - Protocol: Port Numbers
Selects services that match the <protocol>:<port> combination.

[-vserver-policy <svc_vserver_policy>] - Vserver Restrictions
Selects services that match a specific vserver restriction.

[-failover-policy <svc_failover_policy>] - Failover Restrictions
Selects services that match a specific interface failover restriction.

Examples
The following example displays the built-in services.

```plaintext
cluster1::> network interface service show
Service    Protocol:Port
---------------------- --------------
intercluster-core    tcp:11104
                  tcp:11105
management-bgp      tcp:179
2 entries were displayed.
```

network ipspace commands
Manage IP Spaces
Network IPspace commands.

network ipspace create
Create a new IPspace

Availability: This command is available to cluster administrators at the admin privilege level.

Description
IPspaces are distinct IP address spaces in which Storage Virtual Machines (SVMs) reside. The "Cluster" IPspace and "Default" IPspace are created by default. You can create more custom IPspaces when you need your SVMs to have overlapping IP addresses, or you need more control over networking configurations for cluster peering. Please reference the "Network Management Guide" for the limit of how many custom IPspaces are supported on your system.

Parameters
-ipspace <IPspace> - IPspace name

The name of the IPspace to be created.

- The name must contain only the following characters: A-Z, a-z, 0-9, ".", "-" or ".".
- The first character of each label, delimited by ",", must be one of the following characters: A-Z or a-z.
- The last character of each label, delimited by ",", must be one of the following characters: A-Z, a-z or 0-9.
- The maximum supported length is 47 characters.
- The system reserves the following names: "all", "local" and "localhost".
• The system provides the following IPspaces: "Cluster" and "Default".

Examples
The following example creates IPspace "ips1".

```
cluster1::> network ipspace create -name ips1
```

network ipspace delete
Delete an IPspace

Availability: This command is available to cluster administrators at the admin privilege level.

Description
Delete an IPspace that contains no ports or Vservers.

Parameters
-ipspace <IPspace> - IPspace name
The name of the IPspace to be deleted. If the IPspace is associated with one or more logical-interfaces, you must delete them before you can delete the IPspace.

Examples
The following example deletes the IPspace "ips1".

```
cluster1::> network ipspace delete -ipspace ips1
```

network ipspace rename
Rename an IPspace

Availability: This command is available to cluster administrators at the admin privilege level.

Description
Rename an IPspace.

Parameters
-ipspace <IPspace> - IPspace name
The name of the IPspace to be renamed.

-new-name <IPspace> - New Name
The new name for the IPspace.

• The name must contain only the following characters: A-Z, a-z, 0-9, ".", "," or "_".

• The first character of each label, delimited by ".", must be one of the following characters: A-Z or a-z.

• The last character of each label, delimited by ".", must be one of the following characters: A-Z, a-z or 0-9.

• The maximum supported length is 47 characters.

• The system reserves the following names: "all", "cluster", "local" and "localhost".
Examples
The following example renames IPspace "ips1" to "ips2".

```
cluster1::> network ipspace rename -ipspace ips1 -new-name ips2
```

**network ipspace show**
Display IPspace information

*Availability:* This command is available to cluster administrators at the admin privilege level.

**Description**
Display network IPspaces.

**Parameters**
- `[ [-fields <fieldname>, ...]`  
  Specify the fields to be displayed for each IPspace.
- `[ [-instance ]]`  
  Display all parameters of the IPspace objects.
- `[ -ipspace <IPspace> ] - IPspace name`  
  Display the names of the IPspaces.
- `[ -ports <node>:<port>, ...] - Ports`  
  The list of network ports assigned to each IPspace.
- `[ -broadcast-domains <Broadcast Domain>, ...] - Broadcast Domains`  
  The list of broadcast domains that belong to the IPspace.
- `[ -vservers <vserver name>, ...] - Vservers`  
  The list of Vservers assigned to each IPspace.

**Examples**
The following example displays general information about IPspaces.

```
cluster1::> network ipspace show
IPspace            Vserver List                  Broadcast Domains
------------------- ----------------------------- ----------------------------
Cluster             Cluster                       -
Default             cluster1, vs1, vs2          br1, br2, br3
2 entries were displayed.
```

**network ndp commands**
Manage Neighbor Discovery Protocol

Network Discovery Protocol commands.
network ndp default-router commands

Manage default router entries
NDP default router commands.

network ndp default-router delete-all

Delete default routers on a given IPspace

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
The `network ndp default-router delete-all` command deletes default router lists from the specified IPspace.

Parameters

- `--ipspace <IPspace>` - IPspace Name
  Use this parameter to specify the IPspace where the default routers are to be deleted.

Examples

The following example deletes default routers from IPspace ips1.

```
cluster1:*> network ndp default-router delete-all --ipspace ips1
```

network ndp default-router show

Display default routers

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
The `network ndp default-router show` command displays Neighbor Discovery Protocol (NDP) default routers learned on a specified port.

Parameters

`[-fields <fieldname>, ...]`
If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

`[-instance ]`
If you specify the `-instance` parameter, the command displays detailed information about all fields.

`[-node <nodename>|local]` - Node
Displays the NDP default routers from the specified node.

`[-ipspace <IPspace>]` - IPspace name
Displays the NDP default routers from the specified IPspace.

`[-port (<netport>|<ifgrp>)]` - Port
Displays the NDP default routers from the specified port.

`[-router-addr <IP Address>]` - Router Address
Displays the default routers that have the specified IPv6 addresses.
[-flag {none|managed-address-DHCPv6|other-DHCPv6}] - Flag
Displays the default routers that have the specified flag. The flag indicates whether addresses are available via DHCPv6 or other configuration information is available via DHCPv6.

[-expire-time {<integer>d|<integer>h|<integer>m|<integer>s|never|expired}] - Expire Time
Displays the default routers that have the specified expire time.

Examples
The following example displays NDP default routers on local port e0f.

```
cluster1::*> network ndp default-router show -port e0f -node local
Node: node1
IPspace: Default
Port     Router Address             Flag            Expire Time
-------- -------------------------- --------------  --------------
e0f      fe80::5:73ff:fea0:107      none            0d0h23m9s
```

network ndp neighbor commands
Manage neighbor entries
Neighbor Discovery Protocol (NDP) neighbor commands.

network ndp neighbor create
Create a static NDP neighbor entry
Availability: This command is available to cluster and Vserver administrators at the advanced privilege level.

Description
The network ndp neighbor create command creates a static Neighbor Discovery Protocol (NDP) neighbor entry within a Vserver.

Parameters
-vserver <vserver name> - Vserver Name
Use this parameter to specify the Vserver on which the NDP neighbor is to be created.

-neighbor <IP Address> - Neighbor Address
Use this parameter to specify the neighbor's IPv6 address.

-mac-address <MAC Address> - MAC Address
Use this parameter to specify the neighbor's MAC address.

Examples
The following example creates a NDP neighbor entry within Vserver vs0.

```
cluster1::*> network ndp neighbor create -vserver vs0 -neighbor 20:20::20 -mac-address 10:10:10:0:0:1
```

network ndp neighbor delete
Delete a static NDP neighbor entry
Availability: This command is available to cluster and Vserver administrators at the advanced privilege level.
Description
The `network ndp neighbor delete` command deletes a static Neighbor Discovery Protocol (NDP) neighbor from a Vserver.

Parameters
- `vserver <vserver name>` - Vserver Name
  Use this parameter to specify the Vserver on which the NDP neighbor is to be deleted.
- `neighbor <IP Address>` - Neighbor Address
  Use this parameter to specify the neighbor's IPv6 address.

Examples
The following example deletes a NDP neighbor entry within Vserver vs0.
```bash
cluster1:*> network ndp neighbor delete -vserver vs0 -neighbor 20:20::20
```

**network ndp neighbor show**

Display static NDP neighbor entries

Availability: This command is available to cluster and Vserver administrators at the advanced privilege level.

Description
The `network ndp neighbor show` command displays a group of static Neighbor Discovery Protocol (NDP) neighbors within one or more Vservers. You can view static NDP neighbors within specified Vservers, neighbors with specified IPv6 address, and neighbors with specified MAC address.

Parameters
- `{ [-fields <fieldname>, ...] }
  If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.
- `[-instance]`
  If you specify the `-instance` parameter, the command displays detailed information about all fields.
- `[-vserver <vserver name>]` - Vserver Name
  Displays the static NDP neighbors that have the specified Vserver as their origin.
- `[-neighbor <IP Address>]` - Neighbor Address
  Displays the static NDP neighbors that have the specified IPv6 address.
- `[-mac-address <MAC Address>]` - MAC Address
  Displays the static NDP neighbors that have the specified MAC address.

Examples
The following example displays all of the static NDP neighbors configured on Vserver vs0.
```bash
cluster1:*> network ndp neighbor show -vserver vs0
Vserver          Neighbor            MAC Address
----------------- ------------------------ -------------------
vs0              10:10::10              04:04:04:04:04:04
                20:20::20              01:01:01:01:01:01
2 entries were displayed.
```
network ndp neighbor active-entry commands

Manage neighbor active entries
NDP active neighbor commands.

network ndp neighbor active-entry delete

Delete active neighbor entry from a System or Admin Vserver

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
The network ndp neighbor active-entry delete command deletes a Network Discovery Protocol (NDP) neighbor entry on the specified port from a given Vserver's subnet group.

Parameters
- -node {<nodename>|local} - Node
  Use this parameter to specify the node on which the neighbor entry is to be deleted.
- -vserver <vserver> - System or Admin Vserver Name
  Use this parameter to specify the System or Admin Vserver on which the neighbor entry is to be deleted.
- -subnet-group <IP Address/Mask> - Subnet Group
  Use this parameter to specify the subnet group from which the neighbor entry is to be deleted.
- -neighbor <IP Address> - Neighbor
  Use this parameter to specify the IPv6 address of the neighbor entry which is to be deleted.
- -port {<netport>|<ifgrp>} - Port
  Use this parameter to specify the port on which the neighbor entry is to be deleted.

Examples
The following example deletes a neighbor entry from the Admin Vserver cluster1:

```
cluster1::*> network ndp neighbor active-entry delete -vserver cluster1 -node local -subnet-group ::/0 -neighbor fe80:4::5:73ff:fea0:107 -port e0d
```

network ndp neighbor active-entry show

Display active neighbor entries organized by Vserver

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
The network ndp neighbor active-entry show command displays Network Discovery Protocol (NDP) neighbor cache entries on one or more nodes. You can view ndp neighbors within specified nodes and within specified System or Admin Vservers.

Parameters

[-fields <fieldname>, ...]
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use `-fields ?' to display the fields to specify.

[-verbose]
Displays the expire time, state, is-router, and probe count fields.
If you specify the `-instance` parameter, the command displays detailed information about all fields.

- **-instance** - Node
  Displays the NDP neighbors from the specified node.

- **-node <nodename>|local** - Node
  Displays the NDP neighbors from the specified node.

- **-vserver <vserver>** - System or Admin Vserver Name
  Displays the NDP neighbors from the specified System or Admin Vserver. Data and Node Vservers do not have dynamic NDP neighbors.

- **-subnet-group <IP Address/Mask>** - Subnet Group
  Displays the NDP neighbors in the specified subnet group.

- **-neighbor <IP Address>** - Neighbor
  Displays the NDP neighbors that have the specified IPv6 address.

- **-port <netport>|<ifgrp>** - Port
  Displays the NDP neighbors on the specified port.

- **-mac-address <MAC Address>** - MAC Address
  Displays the NDP neighbors have the specified MAC address.

- **-expire-time \[[<integer>d]\[<integer>h]\[<integer>m]\[<integer>s]\|never\|expired\]** - Expire Time
  Displays the NDP neighbors have the specified expire time.

- **-state \[<nostate|incomplete|reachable|stale|delay|probe|unknown>\]** - State
  Displays the NDP neighbors in the specified state.

- **-is-router \[true\|false\]** - Is Router
  Displays the NDP neighbor which is a router.

- **-probe-count <integer>** - Probe Count
  Displays the NDP neighbors with the specified probe count. Probe count is the number of times that this neighbor's MAC address has been queried.

- **-is-static \[true\|false\]** - Is Static
  Displays the NDP neighbors which are statically configured.

**Examples**

The following example displays NDP neighbors on the Admin Vserver cluster1:

```bash
cluster1::*> network ndp neighbor active-entry show -vserver cluster1
Node: node1
Vserver: cluster1
Subnet Group: ::/0
Neighbor                     MAC Address          Port
------------------------------ -------------------- --------
fe80:4::5:73ff:fea0:107      00:05:73:a0:01:07    e0d
fe80:4::226:98ff:fe0c:b6c1   00:26:98:0c:b6:c1    e0d
3 entries were displayed.
```

**network ndp prefix commands**

Manage prefix entries

NDP prefix commands.
network ndp prefix delete-all
Delete IPv6 prefixes on a given IPspace

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
The `network ndp prefix delete-all` command deletes all prefixes learned from the specified IPspace.

Parameters
- `--ipspace <IPspace>` - IPspace Name
  Use this parameter to specify the IPspace where the IPv6 prefixes are to be deleted.

Examples
The following example deletes all IPv6 prefixes within IPspace ips1.
```
cluster1::*> network ndp prefix delete-all --ipspace ips1
```

network ndp prefix show
Display IPv6 prefixes

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
The `network ndp prefix show` command displays IPv6 prefixes on one or more nodes.

Parameters
- `[-fields <fieldname>, ...]`
  If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

  | `-verbose`
  | Displays the valid-lifetime, preferred-lifetime, origin and advertising-router fields.

  | `-instance`
  | If you specify the `-instance` parameter, the command displays detailed information about all fields.

  | `-node {<nodename> | local}]` - Node
  | Displays the IPv6 prefixes from the specified node.

  | `-ipspace <IPspace>` - IPspace name
  | Displays the IPv6 prefixes from the specified IPspace.

  | `-port {<netport> | <ifgrp>}]` - Port
  | Displays the IPv6 prefixes on the specified port.

  | `-prefix <IP Address/Mask>` - Prefix
  | Displays the IPv6 prefixes with the specified prefix value.

  | `-flag {none | on-link | autonomous | on-link-autonomous}]` - Flag
  | Displays the IPv6 prefixes with the specified flag. The flag indicates whether a prefix is on-link and whether it can be used in autonomous address configuration.
Valid Lifetime
Displays the IPv6 prefixes having the specified valid lifetime in seconds.

Preferred Lifetime
Displays the IPv6 prefixes having the specified preferred lifetime in seconds.

Expire Time
Displays the IPv6 prefixes having the specified expire time.

Origin of the Prefix
Displays the IPv6 prefixes with the specified origin.

Router that Advertised the Prefix
Displays the IPv6 prefixes which are propagated by the specified router list.

Examples
The following example displays IPv6 prefixes on port e0f.

```
cluster1:*> network ndp prefix show -port e0f -node local
```

Node: node1
IPspace: Default
Port      Prefix                    Flag               Expire Time
--------- ------------------------- ------------------ -------------
e0f       fd20:8b1e:b255:814e::/64  on-link-autonomous 29d23h56m48s

network options commands
The options directory

network options cluster-health-notifications commands
The cluster-health-notifications directory

network options cluster-health-notifications modify
cluster health notification options

Availability: This command is available to cluster administrators at the admin privilege level.

Description
This command enables or disables cluster health notifications on the specified node.

Parameters
-node {<nodename>|local} - Node
   This parameter specifies the node for which the cluster health notification status will be modified.

-enabled {true|false} - Cluster Health Notifications Enabled
   Setting this parameter to true enables cluster health notification. Setting it to false disables cluster health notification.

Examples
The following example modifies the cluster health notification status for a node:
network options cluster-health-notifications show

Display cluster health notification options

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The network options cluster-health-notifications show command displays whether the node's cluster health notifications are enabled.

Parameters

{[-fields <fieldname>, ...]

If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

| [-instance ]

If you specify the -instance parameter, the command displays detailed information about all fields.

[-node {<nodename>|local}] - Node

This parameter specifies the node for which the cluster health notification status will be displayed.

[-enabled {true|false}] - Cluster Health Notifications Enabled

Selects the entries that match this parameter value.

Examples

The following example displays the cluster health notification status for a node:

```
cluster1::> network options cluster-health-notifications show -node node1
Node: node1
Cluster Health Notifications Enabled: true
```

network options detect-switchless-cluster commands

Manage capability to automatically detect switchless cluster configurations

network options detect-switchless-cluster modify

Modify the status of switchless cluster detection

Availability: This command is available to cluster administrators at the advanced privilege level.

Description

This command enables or disables the automatic detection of a switchless cluster. A switchless cluster consists of two nodes where the cluster ports are directly connected without a switch between them.
Parameters

[-enabled {true|false}] - Enable Switchless Cluster Detection

This parameter specifies whether switchless cluster detection is enabled or not. Setting this parameter to true enables switchless cluster detection.

Examples

The following example enables switchless cluster detection:
cluster1::*> network options detect-switchless-cluster modify -enabled true

network options detect-switchless-cluster show

Display the status of switchless cluster detection

Availability: This command is available to cluster administrators at the advanced privilege level.

Description

The network options detect-switchless-cluster show command displays whether switchless cluster detection is enabled.

Examples

The following example displays whether switchless cluster detection is enabled:
cluster1::*> network options detect-switchless-cluster show
Enable Detect Switchless Cluster: true

network options ipv6 commands

The ipv6 directory

network options ipv6 modify

Modify IPv6 options

Availability: This command is available to cluster administrators at the admin privilege level.

Description

This command sets the state of IPv6 options for the cluster.

Parameters

[-enabled {true}] - IPv6 Enabled

Setting this parameter to true enables IPv6 for the cluster. IPv6 cannot be disabled once it is enabled for the cluster. Call technical support for guidance regarding disabling IPv6.

[-is-ra-processing-enabled {true|false}] - Router Advertisement (RA) Processing Enabled

Setting this parameter to true enables cluster to process IPv6 router advertisements. Setting it to false disables router advertisement processing by the cluster.

Examples

The following example enables IPv6 for the cluster:
cluster1::> network options ipv6 modify -enabled true
network options ipv6 show

Display IPv6 options

Availability: This command is available to cluster administrators at the admin privilege level.

Description
This command displays the current state of IPv6 options for the cluster.

Examples

cluster1::> network options ipv6 show
IPv6 Enabled: false
Router Advertisement (RA) Processing Enabled: false

network options load-balancing commands

The network options load-balancing directory

network options load-balancing modify

Modify load balancing algorithm

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
This command sets the state of geometric mean algorithm for load balancing

Parameters

[-enable |true|false]| - Geometric Mean Algorithm for load balancing

Setting this parameter to true enables the geometric mean algorithm for load balancing. Setting it to false disables the geometric mean algorithm for the cluster.

Examples

The following example will enable the geometric mean algorithm for load balancing.
cluster1::> network options load-balancing modify -enable true

The following example will disable the geometric mean algorithm for load balancing.
cluster1::> network options load-balancing modify -enable false
network options load-balancing show
Display load balancing algorithm
Availability: This command is available to cluster administrators at the advanced privilege level.

Description
This command displays the use of geometric mean load balancing algorithm.

Examples
```
cluster1::> network options load-balancing show
   Geometric Mean Algorithm for load balancing: false
```

network options multipath-routing commands
The multipath-routing directory

network options multipath-routing modify
Modify multipath-routing
Availability: This command is available to cluster administrators at the advanced privilege level.

Description
The network options multipath-routing modify command is used to modify cluster-wide multipath routing configuration.

Parameters
```
[-is-enabled [true|false]] - Is Multipath Routing Enabled
```
This parameter specifies whether multipath routing configuration is enabled or not. Setting this parameter to true enables multipath routing for all nodes in the cluster.

Examples
```
cluster1::> network options multipath-routing modify -is-enabled true
```

network options multipath-routing show
Display multipath-routing
Availability: This command is available to cluster administrators at the advanced privilege level.

Description
The network options multipath-routing show command displays the multipath routing configuration for the cluster.
network options port-health-monitor commands

Manage port health monitor

network options port-health-monitor disable-monitors

Disable one or more port health monitors

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
This command disables the given port health monitors for the given IPspaces in the cluster.

Parameters
-ipspace <IPspace> - IPspace Name
  The name of the IPspace for which the specified port health monitors are disabled.

-health-monitors {l2-reachability|link-flapping|crc-errors|vswitch-link}, ... - List of Port Health Monitors to Disable
  The port health monitors to disable.

Examples
The following example disables the "l2_reachability" health monitor for the "Default" IPspace.

  Note: The status of the "link_flapping" monitor is unaffected by the command.

    cluster1::*> network options port-health-monitor show
    IPspace      Enabled Port Health Monitors
    ------------  ----------------------------
    Cluster       l2_reachability,  
                  link_flapping
    Default       l2_reachability,  
                  link_flapping
    2 entries were displayed.

    cluster1::*> network options port-health-monitor disableMonitors -ipspace Default -health-monitors l2_reachability

    cluster1::*> network options port-health-monitor show
    IPspace      Enabled Port Health Monitors
    ------------  ----------------------------
    Cluster       l2_reachability,  
                  link_flapping
    Default       link_flapping
    2 entries were displayed.
network options port-health-monitor enable-monitors

Enable one or more port health monitors

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
This command enables the given port health monitors for the given IPspaces in the cluster.

Parameters
- **-ipspace <IPspace>** - IPspace Name
  The name of the IPspace for which the specified port health monitors are enabled.

- **-health-monitors {l2-reachability|link-flapping|crc-errors|vswitch-link}, ...** - List of Port Health Monitors to Enable
  The port health monitors to enable. Upon enabling the l2_reachability health monitor, it runs in an "unpromoted" state. While in this state, the monitor does not mark any ports as unhealthy due to the l2_reachability health check. The monitor is promoted in the "Cluster" IPspace when the "Cluster" broadcast domain is found to have passed the l2_reachability health check. An EMS event called "vifmgr.hm.promoted" event is generated when the health monitor is promoted for the IPspace.

Examples
The following example enables the "l2_reachability" health monitor for the "Default" IPspace:

Note: The status of the "link_flapping" monitor is unaffected by the command.

```
cluster1::*> network options port-health-monitor show
IPspace         Enabled Port Health Monitors
-------------   ----------------------------
Cluster         l2_reachability,
                link_flapping
Default         link_flapping
2 entries were displayed.
cluster1::*> network options port-health-monitor enableMonitors -ipspace Default -health-monitors l2_reachability
cluster1::*> network options port-health-monitor show
IPspace         Enabled Port Health Monitors
-------------   ----------------------------
Cluster         l2_reachability,
                link_flapping
Default         l2_reachability,
                link_flapping
2 entries were displayed.
```

network options port-health-monitor modify

Modify port health monitors configuration

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
This command modifies the enabled port health monitors for the given IPspaces in the cluster.
**Parameters**

`-ipspace <IPspace> - IPspace Name`

The name of the IPspace for which enabled port health monitors are modified.

`[-health-monitors (l2-reachability|link-flapping|crc-errors|vswitch-link),...] - List of Enabled Port Health Monitors`

All of the port health monitors that you want to enable. This command enables any port health monitors in this list that are currently disabled, and it disables any currently enabled monitors that are not in this list. Upon enabling the `l2_reachability` health monitor, it runs in an "unpromoted" state. While in this state, the monitor does not mark any ports as unhealthy due to the `l2_reachability` health check. The monitor is promoted in the "Cluster" IPspace when the "Cluster" broadcast domain is found to have passed the `l2_reachability` health check. An EMS event called "vifmgr.hm.promoted" event is generated when the health monitor is promoted for the IPspace.

**Examples**

The following example modifies the port health monitor configuration of the "Default" IPspace such that only the "link_flapping" port health monitor is enabled. enabled for all IPspaces in the cluster.

**Note:** Only the specified monitor is enabled after the modify command is issued.

```
cluster1::*> network options port-health-monitor show
IPspace      Enabled Port Health Monitors
------------- ----------------------------
Cluster      l2_reachability, link_flapping
Default      l2_reachability, link_flapping
2 entries were displayed.
```

```
cluster1::*> network options port-health-monitor modify -ipspace Default -health-monitors link_flapping
```

```
cluster1::*> network options port-health-monitor show
IPspace      Enabled Port Health Monitors
------------- ----------------------------
Cluster      l2_reachability, link_flapping
Default      link_flapping
2 entries were displayed.
```

**network options port-health-monitor show**

Display port health monitors configuration

**Availability:** This command is available to `cluster` administrators at the `advanced` privilege level.

**Description**

This command displays the enabled port health monitors for the IPspaces in the cluster.

**Parameters**

```
[-fields <fieldname>,...]  
If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.
```

```
[-instance]  
If you specify the `-instance` parameter, the command displays detailed information about all fields.
```
[-ipspace <IPspace>] - IPspace Name
Displays the port health monitors that are enabled only for the given IPspace name.

[-health-monitors (l2-reachability|link-flapping|crc-errors|vswitch-link), ...] - List of Enabled Port Health Monitors
Displays the IPspaces that have the given monitors enabled.

Examples
The following example lists all port health monitors that are enabled for all IPspaces in the cluster.

```
cluster1::*> network options port-health-monitor show
              IPspace         Enabled Port Health Monitors
                    --------------    ----------------------------
                    Cluster          l2_reachability,
                                      link_flapping
                    Default          l2_reachability,
                                      link_flapping
2 entries were displayed.
```

network options send-soa commands
Manage Send Start of Authority settings

network options send-soa modify
 Modify Send SOA settings

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
This command sets the status of sending statement of authority record in the DNS response.

Parameters
[-enable {true|false}] - Enable sending SOA
Setting this parameter to true enables sending the statement of authority (SOA) record in the DNS response. Setting it to false disables sending the statement of authority (SOA) record in the DNS response for the cluster.

Examples
The following example will enable the sending of statement of authority (SOA) in the DNS response.
cluster1::> network options send-soa modify -enable true

The following example will disable the sending of statement of authority (SOA) in the DNS response.
cluster1::> network options send-soa modify -enable false

network options send-soa show
Display Send SOA settings

Availability: This command is available to cluster administrators at the advanced privilege level.
**Description**
This command displays whether sending the statement of authority record (SOA) in the DNS response is enabled or not.

<table>
<thead>
<tr>
<th>Examples</th>
</tr>
</thead>
</table>
| cluster1::> network options send-soa show  
  Enable sending SOA: true |

**network options switchless-cluster commands**
Manage switchless cluster options

**network options switchless-cluster modify**
Modify switchless cluster network options

**Availability:** This command is available to cluster administrators at the advanced privilege level.

**Description**
This command sets whether the cluster network is in switchless or switched mode. A switchless cluster is physically formed by connecting two nodes back-to-back, without a switch between them.

**Parameters**
[-enabled {true|false}] - Enable Switchless Cluster

This parameter specifies whether the switchless cluster is enabled or not. Setting this parameter to true enables the switchless cluster.

<table>
<thead>
<tr>
<th>Examples</th>
</tr>
</thead>
</table>
| The following example enables the switchless cluster:  
  cluster1::*> network options switchless-cluster modify -enabled true |

**network options switchless-cluster show**
Display switchless cluster network options

**Availability:** This command is available to cluster administrators at the advanced privilege level.

**Description**
The network options switchless-cluster show command displays the attributes of a switchless cluster.

<table>
<thead>
<tr>
<th>Examples</th>
</tr>
</thead>
</table>
| The following example displays the attributes of the switchless cluster:  
  cluster1::*> network options switchless-cluster show  
  Enable Switchless Cluster: true |
network port commands

Manage network ports

network port delete

Delete a network port

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
The network port delete command deletes a network port that is no longer physically present on the storage system.

Parameters
- `node {<nodename>|local} - Node`
  This specifies the node on which the port is located.
- `port {<netport>|<ifgrp>} - Port`
  This specifies the port to delete.

Examples
The following example deletes port e0c from a node named node0. The command works only when the port does not physically exist on the storage system.

```
cluster1:*> network port delete -node node0 -port e0c
```

network port modify

Modify network port attributes

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The network port modify command enables you to change the maximum transmission unit (MTU) setting, autonegotiation setting, administrative duplex mode, and administrative speed of a specified network port.

The MTU of ports that belong to broadcast-domains must be updated through the broadcast-domain modify command.

Modification of a port’s IPspace will only work before a node is added to a cluster, when the cluster version is below Data ONTAP 8.3, or when the node is offline. To change the IPspace of a port once the node is in a Data ONTAP 8.3 cluster, the port should be added to a broadcast-domain that belongs to that IPspace.

Parameters
- `node {<nodename>|local} - Node`
  Use this parameter to specify the node on which the port is located.
- `port {<netport>|<ifgrp>} - Port`
  Use this parameter to specify the port that you want to modify.
- `[-mtu <integer>] - MTU`
  The port's MTU setting. The default setting for ports in the "Cluster" IPspace is 9000 bytes. All other ports use a default value of 1500 bytes.
- **autonegotiate-admin** *(true|false)* - Auto-Negotiation Administrative
  Whether the port uses Ethernet autonegotiation to determine the highest speed and duplex mode that the port and its endpoint can support. The default setting when you create a port is true.

- **duplex-admin** *(auto|half|full)* - Duplex Mode Administrative
  The administrative setting for the port's duplex mode. This is the duplex mode that you prefer the port to use. Depending on network limitations, the operational value can be different from the administrative setting. The default setting when you create a port is full.

- **speed-admin** *(auto|10|100|1000|10000|40000|25000)* - Speed Administrative
  The administrative speed setting, in megabits per second. This is the speed setting that you prefer the port to use. Depending on network limitations, the operational value can be lower than the administrative setting.

- **flowcontrol-admin** *(none|receive|send|full)* - Flow Control Administrative
  The administrative flow control setting of the port. This is the flow control setting that you prefer the port to use. Depending on network and port limitations, the operational value can be different from the administrative setting.

- **up-admin** *(true|false)* - Up Administrative (privilege: advanced)
  The administrative state of the port. If set to true, the port is used if it is operational. If set to false, the port is configured down.

- **ipspace** `<IPspace>` - IPspace Name
  Use this parameter to specify the IPspace the network port is assigned to. Modification of a port's IPspace will only work before a node is added to a cluster, when the cluster version is below Data ONTAP 8.3, or when the node is offline. To change the IPspace of a port once the node is in a Data ONTAP 8.3 cluster, the port should be added to a broadcast-domain that belongs to that IPspace. If there is an inconsistency between the broadcast-domain and IPspace, this parameter can be set to bring the IPspace into alignment with the broadcast-domain.

- **ignore-health-status** *(true|false)* - Ignore Port Health Status (privilege: advanced)
  Use this parameter to specify that the system ignore network port health status of the specified port for the purpose of hosting a logical interface.

### Examples
The following example modifies port e0a on a node named node0 not to use auto-negotiation, to preferably use half duplex mode, and to preferably run at 100 Mbps.

```bash
cluster1::> network port modify -node node0 -port e0a -autonegotiate-admin false -duplex-admin half -speed-admin 100
```

**network port show**
Display network port attributes

**Availability:** This command is available to cluster and Vserver administrators at the admin privilege level.

**Description**
The network port show command displays information about network ports. The command output indicates any inactive links, and lists the reason for the inactive status.

Some parameters can have "administrative" and "operational" values. The administrative setting is the preferred value for that parameter, which is set when the port is created or modified. The operational value is the actual current value of that parameter. For example, if the network is underperforming due to network problems, the operational speed value can be lower than the administrative setting.
If the operational duplex mode and speed of a port cannot be determined (for instance, if the link is down), that port's status is listed as *undef*, meaning undefined.

**Parameters**

```
[-fields <fieldname>, ...]
```

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

```
[[-health]]
```

Use this parameter to display detailed health information for the specified network ports.

```
[[-instance]]
```

If you specify the `-instance` parameter, the command displays detailed information about all fields.

```
[-node <nodename>|local] - Node
```

Selects the network ports that match this parameter value. Use this parameter with the `-port` parameter to select a port.

```
[-port <netport>|<ifgrp>] - Port
```

Selects the network ports that match this parameter value. If you do not use this parameter, the command displays information about all network ports.

```
[-link {off|up|down}] - Link
```

Selects the network ports that match this parameter value.

```
[-mtu <integer>] - MTU
```

Selects the network ports that match this parameter value.

```
[-autonegotiate-admin {true|false}] - Auto-Negotiation Administrative
```

Selects the network ports that match this parameter value.

```
[-autonegotiate-oper {true|false}] - Auto-Negotiation Operational
```

Selects the network ports that match this parameter value.

```
[-duplex-admin {auto|half|full}] - Duplex Mode Administrative
```

Selects the network ports that match this parameter value.

```
[-duplex-oper {auto|half|full}] - Duplex Mode Operational
```

Selects the network ports that match this parameter value.

```
[-speed-admin {auto|10|100|1000|10000|100000|40000|25000}] - Speed Administrative
```

Selects the network ports that match this parameter value.

```
[-speed-oper {auto|10|100|1000|10000|100000|40000|25000}] - Speed Operational
```

Selects the network ports that match this parameter value.

```
[-flowcontrol-admin {none|receive|send|full}] - Flow Control Administrative
```

Selects the network ports that match this parameter value.

```
[-flowcontrol-oper {none|receive|send|full}] - Flow Control Operational
```

Selects the network ports that match this parameter value.

```
[-mac <MAC Address>] - MAC Address
```

Selects the network ports that match this parameter value.

```
[-up-admin {true|false}] - Up Administrative (privilege: advanced)
```

Selects the network ports that match this parameter value.

```
[-type {physical|if-group|vlan|vip}] - Port Type
```

Selects the network ports that match this parameter value.
[-ifgrp-node <nodename>] - Interface Group Parent Node
Selects the network ports that match this parameter value.

[-ifgrp-port (<netport>|<ifgrp>)] - Interface Group Parent Port
Selects the network ports that match this parameter value.

[-ifgrp-distr-func (mac|ip|sequential|port)] - Distribution Function
Selects the network ports that match this parameter value.

[-ifgrp-mode (multimode|multimode_lacp|singlemode)] - Create Policy
Selects the network ports that match this parameter value.

[-vlan-node <nodename>] - Parent VLAN Node
Selects the network ports that match this parameter value.

[-vlan-port (<netport>|<ifgrp>)] - Parent VLAN Port
Selects the network ports that match this parameter value.

[-vlan-tag <integer>] - VLAN Tag
Selects the network ports that match this parameter value.

[-remote-device-id <text>] - Remote Device ID
Selects the network ports that match this parameter value.

[-ipspace <IPspace>] - IPspace Name
Use this parameter to display information only about the ports that match the IPspace you specify.

[-broadcast-domain <Broadcast Domain>] - Broadcast Domain
Use this parameter to display information only about the ports that match the broadcast-domain you specify.

[-mtu-admin <integer>] - MTU Administrative
Selects the network ports that match this parameter value.

[-health-status (healthy|degraded)] - Port Health Status
Use this parameter to display information only about the ports that match the health-status you specify.

[-ignore-health-status {true|false}] - Ignore Port Health Status
Use this parameter to display information only about the ports that match the ignore-health-status you specify.

[-health-degraded-reasons {l2-reachability|link-flapping|crc-errors|vswitch-link}, ...] - Port Health Degraded Reasons
Use this parameter to display information only about the ports that match the degraded-reason you specify.

[-vm-network-name <text>] - Virtual Machine Network Name
Use this parameter to display information only about the ports that match the network name you specify.
Google Cloud Platform only.

Examples
The following example displays information about all network ports.

```
cluster1::> network port show
Node: node1
                  Speed(Mbps) Health   Health
Port      IPspace      Broadcast Domain Link  MTU      Admin/Oper  Status   Status
--------- ------------ ---------------- ---- ---- ----------- -------- ------
e0a       Cluster      Cluster          up   9000  auto/1000  healthy  false
e0b       Cluster      Cluster          up   9000  auto/1000  healthy  false
e0c       Default      Default          up   1500  auto/1000  degraded false

**network port show-address-filter-info**

Print the port's address filter information

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**
The network port show-address-filter-info command displays information about the port's address filter.

**Parameters**

\{[-fields <fieldname>, ...]

If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use -fields ? to display the fields to specify.

| [-instance ]]|

If you specify the -instance parameter, the command displays detailed information about all fields.

- **-node <nodename>** - Node
  Use this parameter to specify the node.

- **-port <netport>|<ifgrp>** - Port
  Use this parameter to specify the port. For example, e0c.

- **[-num-total <integer>]** - Total Number Of Entries
  Use this parameter to specify the total number of entries.

- **[-num-used <integer>]** - Number Of Used Entries
  Use this parameter to specify the number of used entries.
[-used-entries <text>,...] - The Used Entries

Use this parameter to list the used entries.

Examples
The following example displays information of the given port's address filter on the specified node of the cluster.

```
cluster1::*> network port show-address-filter-info -node local -port e0c
```

<table>
<thead>
<tr>

Manage broadcast domains

Manage broadcast domains

Network port broadcast-domain commands. A broadcast domain object is used to define a layer 2 broadcast domain network configuration. It is used to group the ports which belong to the same layer 2 network.

network port broadcast-domain add-ports

Add ports to a layer 2 broadcast domain

Availability: This command is available to cluster administrators at the admin privilege level.

Description
Add ports to a broadcast domain.

Note: The IPSpace of the ports added will be updated to the IPSpace of the broadcast-domain. The ports will be added to the failover-group of the broadcast-domain. The MTU of the ports will be updated to the MTU of the broadcast-domain.

Parameters
- -ipspace <IPspace> - IPspace Name
  The IPspace of the broadcast domain.
- -broadcast-domain <Broadcast Domain> - Layer 2 Broadcast Domain
  The broadcast domain for this port assignment.
- -ports <<node>:<port>>, ... - List of ports
  The ports to be added to this broadcast domain.

Examples
The following example adds the port "e0d" on node "cluster1-1" and port "e0d" on node "cluster1-2" to broadcast domain "mgmt" in IP space "Default".

```
cluster1::network port broadcast-domain> add-ports -ipspace Default -broadcast-domain mgmt -ports cluster1-1:e0d, cluster1-2:e0d
```
network port broadcast-domain create

Create a new layer 2 broadcast domain

Availability: This command is available to cluster administrators at the admin privilege level.

Description
Create a new broadcast domain.

Note: The IPSpace of the ports added will be updated to the IPSpace of the broadcast-domain. A failover-group will be generated containing the ports of the broadcast-domain. The MTU of all of the ports in the broadcast-domain will be updated to the MTU specified for the broadcast-domain.

Parameters
[-ipspace <IPspace>] - IPSpace Name
The IPSpace to which the new broadcast domain belongs.

-broadcast-domain <Broadcast Domain> - Layer 2 Broadcast Domain
The name of the broadcast domain to be created. The name of the broadcast domain needs to be unique within the IPSpace.

-mtu <integer> - Configured MTU
MTU of the broadcast domain.

[-ports <node>:<port>, ...] - Ports
The network ports to be added to the broadcast domain. Ports need to be added to the broadcast domain before interfaces can be hosted on the port. By default, no port will be added to the broadcast domain.

Examples
The following example creates broadcast domain "mgmt" in IPSpace "Default" with an MTU of 1500 and network ports e0c from node "gx1" and node "gx2".

    cluster1::> network port broadcast-domain create -ipspace Default -broadcast-domain mgmt -mtu 1500 -ports gx1:e0c,gx2:e0c

network port broadcast-domain delete

Delete a layer 2 broadcast domain

Availability: This command is available to cluster administrators at the admin privilege level.

Description
Delete a broadcast domain that contains no ports.

Parameters
-ipspace <IPspace> - IPSpace Name
The IPSpace to which the broadcast domain belongs

-broadcast-domain <Broadcast Domain> - Layer 2 Broadcast Domain
The name of the broadcast domain to be deleted.

Examples
The following example deletes the broadcast domain "mgmt" in IPSpace "Default".

    cluster1::> network port broadcast-domain delete -ipspace Default -broadcast-domain mgmt
network port broadcast-domain merge
Merges two layer 2 broadcast domains

Availability: This command is available to cluster administrators at the admin privilege level.

Description
Merges a broadcast domain into an existing broadcast domain.

Parameters
- ipspace <IPspace> - IPspace Name
  The IPspace of the broadcast domain.
- broadcast-domain <Broadcast Domain> - Layer 2 Broadcast Domain
  The merging broadcast domain.
- into-broadcast-domain <Broadcast Domain> - Merge with This Layer 2 Broadcast Domain
  The target broadcast domain for the merge operation.

Examples
The following example merges broadcast domain "bd-mgmt" in IPspace "Default" to broadcast domain "bd-data".

```
cluster1::network port broadcast-domain> merge -ipspace Default -broadcast-domain bd-mgmt -into-broadcast-domain bd-data
```

network port broadcast-domain modify
Modify a layer 2 broadcast domain

Availability: This command is available to cluster administrators at the admin privilege level.

Description
Modify a broadcast domain.

Parameters
- ipspace <IPspace> - IPspace Name
  The IPspace to which the broadcast domain belongs.
- broadcast-domain <Broadcast Domain> - Layer 2 Broadcast Domain
  The name of the broadcast domain.
- mtu <integer> - Configured MTU
  MTU of the broadcast domain.

Examples
The following example modifies the mtu attribute of broadcast domain "mgmt" in IPspace "Default" to 1500

```
cluster1::network port broadcast-domain*> modify -ipspace Default -broadcast-domain mgmt -mtu 1500
```
network port broadcast-domain remove-ports

Remove ports from a layer 2 broadcast domain

Availability: This command is available to cluster administrators at the admin privilege level.

Description
Remove port assignments from a broadcast domain.

Parameters
- **-ipspace <IPspace>** - IPspace Name
  The IPspace of the broadcast domain.
- **-broadcast-domain <Broadcast Domain>** - Layer 2 Broadcast Domain
  The broadcast domain of the ports.
- **-ports <<node>:<port>>, ... - List of ports**
  The ports to removed from the broadcast-domain.

Examples
The following example removes port "e0d" on node "cluster1-1" and port "e0d" on node "cluster1-2" from broadcast domain "mgmt" in IPspace "Default".

```
cluster1::network port broadcast-domain> remove-ports -ipspace Default -broadcast-domain mgmt -ports cluster1-1:e0d, cluster1-2:e0d
```

network port broadcast-domain rename

Rename a layer 2 broadcast domain

Availability: This command is available to cluster administrators at the admin privilege level.

Description
Rename a broadcast domain.

Parameters
- **-ipspace <IPspace>** - IPspace Name
  The IPspace to which the broadcast domain belongs.
- **-broadcast-domain <Broadcast Domain>** - Layer 2 Broadcast Domain
  The name of the broadcast domain.
- **-new-name <text>** - New Name
  The new name of the broadcast domain.

Examples
The following example renames the broadcast domain named "mgmt" to "mgmt2" in IPspace "Default".

```
cluster1::network port broadcast-domain> rename -ipspace Default -broadcast-domain mgmt -new-name mgmt2
```
network port broadcast-domain show

Display layer 2 broadcast domain information

Availability: This command is available to cluster administrators at the admin privilege level.

Description
Display broadcast domain information.

Parameters

<table>
<thead>
<tr>
<th>[-fields &lt;fieldname&gt;, ...]</th>
</tr>
</thead>
</table>
| If you specify the `[-fields <fieldname>, ...]` parameter, the command output also includes the specified field or fields. You can use `'-fields ?'` to display the fields to specify.

<table>
<thead>
<tr>
<th>[-instance]</th>
</tr>
</thead>
</table>
| If you specify the `[-instance]` parameter, the command displays detailed information about all fields.

|-ipspace <IPspace> - IPspace Name
Selects the broadcast domains that match the IPspace name.

|-broadcast-domain <Broadcast Domain> - Layer 2 Broadcast Domain
Selects the broadcast domains that match the broadcast domain name.

|-mtu <integer> - Configured MTU
Selects the broadcast domains that match the MTU value. This field is the MTU that was configured by the user, which might be different from the operational MTU.

|-ports <<node>:<port>>, ...] - Ports
Selects the broadcast domains that contain the network ports. For example, node1:e0a will display broadcast domains that contain node1:e0a network port.

|-port-update-status {complete|in-progress|error|overridden-while-offline}, ...] - Port Update Status
Selects the broadcast domains that contain the network port status. For example, specifying "error" will display broadcast domains that contain "Error" network port status.

|-port-update-status-details <text>, ...] - Status Detail Description
Selects the broadcast domains that contain the network port status detail text.

|-port-update-status-combined {complete|in-progress|error|overridden-while-offline}] - Combined Port Update Status
Selects the broadcast domains that contain the combined network port status. For example, specifying "error" will display broadcast domains that contain a combined network port status of "Error".

|-failover-groups <failover-group>, ...] - Failover Groups
Selects the broadcast domains that contain the failover groups.

|-subnet-names <subnet name>, ...] - Subnet Names
Selects the broadcast domains that contain the subnet name or names.

|-is-vip {true|false}] - Is VIP Broadcast Domain
Selects the broadcast domains that match a specific "is-vip" flag. Specifying "true" matches only broadcast domains associated with the Virtual IP feature; "false" matches only broadcast domains that do not.

Examples
The following example displays general information about broadcast domains.
network port broadcast-domain split

Splits a layer 2 broadcast domain into two layer 2 broadcast domains.

Availability: This command is available to cluster administrators at the admin privilege level.

Description
Splits ports from a broadcast domain into a new broadcast domain.

The following restrictions apply to this command:

• If the ports are in a failover group, all ports in the failover group must be provided. Use `network interface failover-groups show` to see which ports are in failover groups.

• If the ports have LIFs associated with them, the LIFs cannot be part of a subnet’s ranges and the LIF’s curr-port and home-port must both be provided. Use `network interface show -fields subnet-name, home-node, home-port, curr-node, curr-port` to see which ports have LIFs associated with them and whether the LIFs are part of a subnet’s ranges. Use `network subnet remove-ranges` with the LIF’s IP address and `-force-update-lif-associations` set to true to remove the LIF’s association with a subnet.

Parameters
- `ipspace <IPspace>` - IPspace Name
  The IPspace of the broadcast domain.

- `broadcast-domain <Broadcast Domain>` - Layer 2 Broadcast Domain
  The broadcast domain to split.

- `new-broadcast-domain <Broadcast Domain>` - New Layer 2 Broadcast Domain Name
  The new broadcast domain.

- `ports <<node>:<port>>, ...` - List of Ports
  The ports to be split from this broadcast domain.

Examples
The following example splits port "e0d" on node "cluster1-1" and port "e0d" on node "cluster1-2" from broadcast domain "bd-mgmt" in IPspace "Default" to broadcast domain "bd-data".

```
class1::> network port broadcast-domain split -ipspace Default -broadcast-domain bd-mgmt -new-broadcast-domain bd-data -ports cluster1-1:e0d, cluster1-2:e0d
```

network port ifgrp commands

The network port ifgrp directory

network port ifgrp add-port

Add a port to an interface group

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The network port ifgrp add-port command adds a network port to a port interface group. The port interface group must already exist. You can create a port interface group by using the network port ifgrp create command.

The following restrictions apply to port interface groups:

• A port that is already a member of a port interface group cannot be added to another port interface group.
• Cluster ports and management ports cannot be in a port interface group.
• A port to which a logical interface is already bound cannot be added to a port interface group.
• A port that already has an assigned failover role cannot be added to a port interface group.
• A VLAN port cannot be added to a port interface group.
• A port which attaches to a VLAN cannot be added to a port interface group.
• An interface group port cannot be added to a port interface group.
• A port that is assigned to a broadcast domain cannot be added to a port interface group.
• All ports in a port interface group must be physically located on the same node.

Parameters

-node {<nodename>|local} - Node
The node on which the port interface group is located.

-ifgrp <ifgrp name> - Interface Group Name
The port interface group to which a port is to be added.

-port <netport> - Specifies the name of port.
The network port that is to be added to the port interface group.

Examples

The following example adds port e0c to port interface group a1a on a node named node1:

cluster1::> network port ifgrp add-port -node node1 -ifgrp a1a -port e0c

Related references

network port ifgrp create on page 398

network port ifgrp create

Create a port interface group

Availability: This command is available to cluster administrators at the admin privilege level.
Description
The `network port ifgrp create` command creates a port interface group. See the documentation for the `network port ifgrp add-port` command for a list of restrictions on creating port interface groups.

Parameters

- **node `<nodename> | local`** - Node
  The node on which the port interface group will be created.

- **ifgrp `<ifgrp name>`** - Interface Group Name
  The name of the port interface group that will be created. Port interface groups must be named using the syntax "a<number><letter>", where <number> is an integer in the range [0-999] without leading zeros and <letter> is a lowercase letter. For example, "a0a", "a0b", "a1c", and "a2a" are all valid port interface group names.

- **distr-func `{mac | ip | sequential | port}`** - Distribution Function
  The distribution function of the port interface group that will be created. Valid values are:
  
  - mac - Network traffic is distributed based on MAC addresses
  - ip - Network traffic is distributed based on IP addresses
  - sequential - Network traffic is distributed in round-robin fashion from the list of configured, available ports
  - port - Network traffic is distributed based on the transport layer (TCP/UDP) ports

- **mode `{multimode | multimode_lacp | singlemode}`** - Create Policy
  The create policy for the interface group that will be created. Valid values are:
  
  - multimode - Bundle multiple member ports of the interface group to act as a single trunked port
  - multimode_lacp - Bundle multiple member ports of the interface group using Link Aggregation Control Protocol
  - singlemode - Provide port redundancy using member ports of the interface group for failover

Examples

The following example creates a port interface group named a0a on node node0 with a distribution function of ip:

```
cluster1::> network port ifgrp create -node node0 -ifgrp a0a -distr-func ip -mode multimode
```

network port ifgrp delete

Destroy a port interface group

**Availability:** This command is available to `cluster` administrators at the `admin` privilege level.

**Description**

The `network port ifgrp delete` command destroys a port interface group.

**Note:** When you delete an interface group port, it is automatically removed from failover rules and groups to which it belongs.
Parameters
- **node** *(<nodename>|local)* - **Node**
  The node on which the port interface group is located.

- **ifgrp** *(<ifgrp name>)* - **Interface Group Name**
  The port interface group that will be deleted.

Examples
The following example deletes port interface group a0b from a node named node0.

```text
cluster1:/> network port ifgrp delete -node node0 -ifgrp a0b
```

**network port ifgrp remove-port**

Remove a port from an interface group

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**
The *network port ifgrp remove-port* command removes a network port from a port interface group.

Parameters
- **node** *(<nodename>|local)* - **Node**
  The node on which the port interface group is located.

- **ifgrp** *(<ifgrp name>)* - **Interface Group Name**
  The port interface group from which a port will be removed.

- **port** *(<netport>)* - **Specifies the name of port.**
  The network port that will be removed from the port interface group.

Examples
The following example removes port e0d from port interface group a1a on a node named node1:

```text
cluster1:/> network port ifgrp remove-port -node node1 -ifgrp a1a -port e0d
```

**network port ifgrp show**

Display port interface groups

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**
The *network port ifgrp show* command displays information about port interface groups. By default, it displays information about all port interface groups on all nodes in the cluster.

Parameters

```bash
{ [-fields <fieldname>], ...] 
```
If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

```bash
[ [-instance ]] 
```
If you specify the `-instance` parameter, the command displays detailed information about all fields.
[-node {<nodename>|local}] - Node
Selects the port interface groups that match this parameter value. Use this parameter with the -ifgrp
parameter to select information about a specific port interface group.

[-ifgrp <ifgrp name>] - Interface Group Name
Selects the port interface groups that match this parameter value. Use this parameter with the -node
parameter, to select information about a specific port interface group.

[-distr-func {mac|ip|sequential|port}] - Distribution Function
Selects the port interface groups that match this parameter value.

[-mode {multimode|multimode_lacp|singlemode}] - Create Policy
Selects the port interface groups that match this parameter value.

[-mac <MAC Address>] - MAC Address
Selects the port interface groups that match this parameter value.

[-activeports {full|partial|none}] - Port Participation
Selects the port interface groups that match this parameter value. The value "partial" indicates that some but
not all of the port interface group's ports are active. The value "full" indicates that all of the port interface
group's ports are active.

[-ports {<netport>|<ifgrp>}, ...] - Network Ports
Selects the port interface groups that match this parameter value.

[-up-ports {<netport>|<ifgrp>}, ...] - Up Ports
Selects the port interface groups that match this parameter value. Displays only the ports that are up.

[-down-ports {<netport>|<ifgrp>}, ...] - Down Ports
Selects the port interface groups that match this parameter value. Displays only the ports that are down.

Examples
The following example displays information about all port interface groups.

```
cluster1::> network port ifgrp show
  Node | Port | Distribution | MAC Address | Active Ports | Ports
  ---- | ---- | ----------- | ---------- | ------------ | ----
  node0 | a0a | ip | b8:f8:7a:20:00 | partial | e0c
  node1 | a1a | ip | 07:26:60:02:00 | full | e0d
```

network port vip commands
Manage VIP ports

network port vip create
Create a VIP port

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
The network port vip create command creates a VIP port in the specified IPspace on the specified node. Only one VIP
port can be created per IPspace on the given node.
Parameters

- **node** *(<nodename>|local)* - Node
  
The node where the VIP port should be created.

- **port** *(<netport>)* - Network Port
  
The name of the VIP port to be created in the format v<slot-number><port-letter>

- **ipspace** *(<IPspace>)* - IPspace Name
  
The IPspace where the VIP port should be created. The default value for this parameter is "Default", which identifies the default IPspace.

Examples

This example shows how to create a VIP port named v0a in ipspace ips on node1.

```
cluster1::> network port vip create -node node1 -port v0a -ipspace ips
```

network port vip delete

Delete a VIP port

Availability: This command is available to cluster administrators at the advanced privilege level.

Description

The network port vip delete command deletes a VIP port.

Parameters

- **node** *(<nodename>|local)* - Node
  
The node associated with the VIP port to be deleted.

- **port** *(<netport>)* - Network Port
  
The name of the VIP port to be deleted.

Examples

This example shows how to delete VIP Port v0a on node1.

```
cluster1::> network port vip delete -node node1 -port v0a
```

network port vip show

Display VIP ports

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The network port vip show command displays information about VIP ports.

Parameters

{ [ -fields *(<fieldname>)*,... ]
  
  If you specify the -fields *(<fieldname>)*,... parameter, the command output also includes the specified field or fields. You can use -fields ? to display the fields to specify.}
If you specify the -instance parameter, the command displays detailed information about all fields.

```
[-node {<nodename>|local}] - Node
This parameter selects the VIP ports that match the specified node.
```

```
[-port <netport>] - Network Port
This parameter selects the VIP ports that match the specified port.
```

```
[-ipspace <IPspace>] - IPspace Name
This parameter selects the VIP ports that match the specified IPspace.
```

### Examples

The example below shows VIP port v0a is created in IPspace ips on node1.

```
cluster1::> network port vip show
Node   VIP Port IPspace
------ -------- -------------
node1  v0a      ips
```

---

**network port vlan commands**

The network port vlan directory

**network port vlan create**

Create a virtual LAN (VLAN)

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**

The `network port vlan create` command attaches a VLAN to a network port on a specified node.

**Parameters**

```
-node {<nodename>|local} - Node
The node to which the VLAN is to be attached.
```

**Note:** You cannot attach a VLAN to a cluster port.

```
{ -vlan-name <netport>|<ifgrp> } - VLAN Name
The name of the VLAN that is to be attached. This name should be a combination of the name of the port or interface group and the VLAN ID, with a hyphen between, such as "e1c-80".
```

```
| -port <netport>|<ifgrp> - Associated Network Port
The network port to which the VLAN is to be attached.
```

```
-vlan-id <integer> - Network Switch VLAN Identifier
The ID tag of the created VLAN.
```

### Examples

This example shows how to create VLAN e1c-80 attached to network port e1c on node1.

```
cluster1::> network port vlan create -node node1 -vlan-name e1c-80
```
network port vlan delete

Delete a virtual LAN (VLAN)

Availability: This command is available to cluster administrators at the admin privilege level.

**Description**
The `network port vlan delete` command deletes a VLAN from a network port.

**Note:** When you delete a VLAN port, it is automatically removed from all failover rules and groups that use it.

**Parameters**
- `-node <nodename>|local` - Node
  The node from which the VLAN is to be deleted.
- `{ -vlan-name <netport>|<ifgrp> }` - VLAN Name
  The name of the VLAN that is to be deleted
- `{ -port <netport>|<ifgrp> }` - Associated Network Port
  The network port to which the VLAN is to be attached.
- `-vlan-id <integer>` - Network Switch VLAN Identifier
  The ID tag of the deleted VLAN.

**Examples**
This example shows how to delete VLAN e1c-80 from network port e1c on node1.

```
cluster1::> network port vlan delete -node node1 -vlan-name e1c-80
```

network port vlan show

Display virtual LANs (VLANs)

Availability: This command is available to cluster administrators at the admin privilege level.

**Description**
The `network port vlan show` command displays information about network ports that are attached to VLANs. The command output indicates any inactive links and lists the reason for the inactive status.

If the operational duplex mode and speed cannot be determined (for instance, if the link is down), they are listed as `undef`, meaning undefined.

**Parameters**
- `[-fields <fieldname>, ...]`
  If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.
- `[-instance ]`
  If you specify the `-instance` parameter, the command displays detailed information about all fields.
- `-node <nodename>|local` - Node
  Selects the VLAN network ports that match this parameter value.
- `{ -vlan-name <netport>|<ifgrp> }` - VLAN Name
  Selects the VLAN network ports that match this parameter value.
-port <netport>|<ifgrp>\] - Associated Network Port
Selects the VLAN network ports that match this parameter value. If neither this parameter nor -name are used, the command displays information about all network ports.

-vlan-id <integer>\] - Network Switch VLAN Identifier
Selects the VLAN network ports that match this parameter value.

-mac <MAC Address>\] - MAC address
Selects the VLAN network ports that match this parameter value.

Examples

<table>
<thead>
<tr>
<th>Node</th>

</tbody>
</table>

network qos-marking commands

The qos-marking directory

network qos-marking modify

Modify the QoS marking values

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The network qos-marking modify command modifies the QoS marking values for different protocols, for each IPspace.

Parameters

-ipspace <IPspace> - IPspace name
Use this parameter to specify the IPspace for which the QoS marking entry is to be modified.

-protocol <text> - Protocol
Use this parameter to specify the protocol for which the QoS marking entry is to be modified. The possible values are NFS, CIFS, iSCSI, SnapMirror, SnapMirror-Sync, NDMP, FTP, HTTP-admin, HTTP-filesrv, SSH, Telnet, and SNMP.

-dscp <integer>\] - DSCP Marking Value
Use this parameter to specify the DSCP value. The possible values are 0 to 63.

-is-enabled \{true|false\} - Is QoS Marking Enabled
Use this parameter to enable or disable the QoS marking for the specified protocol and IPspace.

Examples
The following example modifies the QoS marking entry for the NFS protocol in the Default IPspace:

cluster1::> network qos-marking modify -ipspace Default -protocol NFS -dscp 10 -is-enabled true
network qos-marking show

Display the QoS marking values

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**
The `network qos-marking show` command displays the QoS marking values for different protocols, for each IPspace.

**Parameters**

`[-fields <fieldname>,...]`

Use this parameter to display only certain fields of the QoS marking table.

`[-instance]`

Use this parameter to display all the fields of the QoS marking table.

`[-ipspace <IPspace>] - IPspace name`

Use this parameter to display the QoS marking entries for the specified IPspace.

`[-protocol <text>] - Protocol`

Use this parameter to display the QoS marking entries for the specified protocol. The possible values are NFS, CIFS, iSCSI, SnapMirror, SnapMirror-Sync, NDMP, FTP, HTTP-admin, HTTP-filesrv, SSH, Telnet, and SNMP.

`[-dscp <integer>] - DSCP Marking Value`

Use this parameter to display the QoS marking entries matching the specified DSCP value. The possible values are 0 to 63.

`[-is-enabled {true|false}] - Is QoS Marking Enabled`

Use this parameter to display the QoS marking entries matching the specified flag.

**Examples**
The following example displays the QoS marking entries for the Default IPspace.

```
cluster1::> network qos-marking show -ipspace Default
IPspace           Protocol           DSCP  Enabled?
-------------------- ----------------- -----  --------
Default
               CIFS                 10  false
               FTP                  48  false
               HTTP-admin           48  false
               HTTP-filesrv         10  false
               NDMP                 10  false
               NFS                  10  true
               SNMP                 48  false
               SSH                  48  false
               SnapMirror           10  false
               SnapMirror-Sync      10  false
               Telnet               48  false
               iSCSI                10  false
12 entries were displayed.
```

**network route commands**

Manage routing tables

Network route commands.
network route create

Create a static route

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

**Description**
The `network route create` command creates a static route within a Vserver.

**Parameters**
- `vserver <vserver>` - Vserver Name
  Use this parameter to specify the Vserver on which the route is to be created.
- `destination <IP Address/Mask>` - Destination/Mask
  Use this parameter to specify the IP address and subnet mask of the route's destination. The format for this value is: address, slash (/), mask. `0.0.0.0/0` is a valid destination value to create default IPv4 route. And `::/0` is a valid destination value to create default IPv6 route.
- `gateway <IP Address>` - Gateway
  Use this parameter to specify the IP address of the gateway server leading to the route's destination.
- `[metric <integer>]` - Metric
  Use this parameter to specify the metric of the route.

**Examples**
The following example creates default routes within Vserver vs0 for IPv4 and IPv6.

```
cluster1::> network route create -vserver vs0 -destination 0.0.0.0/0 -gateway 10.61.208.1
cluster1::> network route create -vserver vs0 -destination ::/0 -gateway 3ffe:1::1
```

network route delete

Delete a static route

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

**Description**
The `network route delete` command deletes a static route from a Vserver.

**Parameters**
- `vserver <vserver>` - Vserver Name
  Use this parameter to specify the Vserver on which the route is to be deleted.
- `destination <IP Address/Mask>` - Destination/Mask
  Use this parameter to specify the IP address and subnet mask of the route's destination. The format for this value is: address, slash (/), mask. For example, `0.0.0.0/0` is a correctly formatted value for the -destination parameter.
- `gateway <IP Address>` - Gateway
  Use this parameter to specify the gateway on which the route is to be deleted.

**Examples**
The following example deletes a route within Vserver vs0 for destination 0.0.0.0/0.

```
```
network route show

Display static routes

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The network route show command displays a group of static routes within one or more Vservers. You can view routes within specified Vservers, routes with specified destinations, and routes with specified gateways.

Parameters

\(-fields\ <fieldname>,...\)
Use this parameter to display only certain fields of the routing tables.

\(-instance\)
Use this parameter to display all fields of the routing tables.

\(-vserver\ <vserver>\) - Vserver Name
Use this parameter to display only routes that have the specified Vserver as their origin.

\(-destination\ <IP\ Address/\Mask>\) - Destination/Mask
Use this parameter to display only routes that have the specified IP address and subnet mask as their destination. The format for this value is: address, slash ("/"), mask. The example below has 0.0.0.0/0 as a valid value for the -destination parameter.

\(-gateway\ <IP\ Address>\) - Gateway
Use this parameter to display only routes that have the specified IP address as their gateway.

\(-metric\ <integer>\) - Metric
Use this parameter to display only routes that have the specified metric.

\(-ipspace\ <IPspace>\) - IPspace Name
Use this parameter to optionally specify the IPspace associated with the Vserver. This parameter can be used in conjunction with the Vserver parameter in order to configure the same route across multiple Vservers within an IPspace.

\(-address-family\ {ipv4|ipv6|ipv6z}\) - Address family of the route
Use this parameter to display only the routes that have the specified address-family.

Examples
The following example displays information about all routing groups.

```
cluster1::> network route show
(network route show)
Server      Destination     Gateway         Metric
------------------- -------------- ------------ ---
node1       0.0.0.0/0     10.61.208.1     20
node2       0.0.0.0/0     10.61.208.1     20
vs0          0.0.0.0/0    10.61.208.1     20
3 entries were displayed.
```
network route show-lifs

Show the Logical Interfaces for each route entry

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The network route show-lifs command displays the association of static routes and Logical Interfaces (LIFs) within one or more Vservers. You can view routes within specified Vservers, routes with specified destinations, and routes with specified gateways.

Parameters
{ [-fields <fieldname>, ...]
    If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use ‘-fields ?’ to display the fields to specify.
}
| [-instance ]
    If you specify the -instance parameter, the command displays detailed information about all fields.

[-vserver <vserver>] - Vserver Name
    Use this parameter to display only routes that have the specified Vserver as their origin.

[-destination <IP Address/ Mask>] - Destination/ Mask
    Use this parameter to display only routes that have the specified IP address and subnet mask as their destination. The format for this value is: address, slash (“/”), mask. For example, 0.0.0.0/0 is a valid value for the -destination parameter.

[-gateway <IP Address>] - Gateway
    Use this parameter to display only routes that have the specified IP address as their gateway.

[-lifs <lif-name>, ...] - Logical Interfaces
    Use this parameter to display only the routes that are associated with the specified Logical Interfaces (LIFs).

[-address-family {ipv4 | ipv6 | ipv6z}] - Address Family
    Use this parameter to display only the routes that belong to specified address family.

network route active-entry commands

Active routes
Dynamic network route commands.

network route active-entry show

Display active routes

Availability: This command is available to cluster and Vserver administrators at the advanced privilege level.

Description
The network route active-entry show command displays installed routes on one or more nodes. You can view routes within specified nodes, within specified Vservers, routes in specified subnet groups, and routes with specified destinations.

Parameters
{ [-fields <fieldname>, ...]
    If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use ‘-fields ?’ to display the fields to specify.
}
Use this parameter to display the reference count, use, interface, and Path MTU fields.

If you specify the -instance parameter, the command displays detailed information about all fields.

Displays the routes that have the specified Vserver as their origin.

Displays the routes from the specified node.

Displays the routes that have the specified IP address type.

Displays the group of routes that belong to the specified subnet. Routes within the specified subnet group are used first before the default set. The "default" subnet group is a system-provided set of default routes.

Displays the routes that have the specified IP address or subnet as their destination. The format for the subnet is: <address>/<mask>. IPv6 address includes the scope value after percentage ("%"). 0.0.0.0/0, 169.254.4.60, ff02::%e0a/32 and fe80::250:56ff:fea6:db7c%e0b are valid values for this parameter.

Displays the routes that use the specified interface to transmit packets to the destination. A valid interface has the format of {<netport>|<ifgrp>}, such as "e0a", "e0a-1" and "a0a", or it can be a loopback interface, such as "lo" and "losk".

Displays the routes that use the specified IP address on the transmit interface.

Displays the routes that have the specified gateway. The gateway can be an IP address, such as "10.10.2.1" and "fe80::1%lo", MAC address, such as "0:5:73:a0:1:7" or refer to a local link, such as "link#3".

Displays the routes that have the specified metric.

Displays the routes that have the specified flags. The type string for "-flags" needs to be one or more of the following {U|G|H|R|D|S|1|2|L|C} in the order shown.

- U - Usable
- G - Gateway
- H - Host
- R - Reject
- D - Dynamic
- S - Static
- 1 - Protocol1
- 2 - Protocol2
- L - Llinfo
- C - Clone
Multiple values can be specified (for example: UHL).

\[-reference-count \leq \text{integer}\] - Reference Count

Displays the routes that have the specified reference count in the system.

\[-lookup-count \leq \text{integer}\] - Lookup Count

Displays the routes that have the specified use count (the count of lookups for the route).

\[-path-mtu \leq \text{integer}\] - Path MTU

Displays the routes that have the specified path maximum transmission unit.

### Examples

The following example displays active routes on all nodes in Vserver vs0 with subnet-group 10.10.10.0/24.

```
cluster1:*> network route active-entry show -vserver vs0 -subnet-group 10.10.10.0/24
(network route active-entry show)

Vserver: vs0
Node: node1
Subnet Group: 10.10.10.0/24
  Destination             Gateway              Interface   Metric  Flags
  ----------------------  -------------------  ---------   ------  -----  
  default                 10.10.10.1           e0c              0  UGS

Vserver: vs0
Node: node2
Subnet Group: 10.10.10.0/24
  Destination             Gateway              Interface   Metric  Flags
  ----------------------  -------------------  ---------   ------  -----  
  default                 10.10.10.1           e0c              0  UGS
2 entries were displayed.
```

### Related references

*network route show* on page 408

### network subnet commands

The subnet directory

Network Subnet commands. These commands are used to define a subnet with its gateway and groups of IP addresses. The IP addresses can be used to create interfaces.

### network subnet add-ranges

Add new address ranges to a subnet

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**

Add new address ranges to a subnet.

**Note:** All addresses in a range must be the same address family (IPv4 or IPv6) and must have the same subnet mask. Ranges that overlap or are next to existing ranges will be merged with the existing ranges.

**Parameters**

\[-ipspace \leq \text{IPspace}\] - IPspace Name

The IPspace in which the range resides.
network subnet create

Create a new layer 3 subnet

Availability: This command is available to cluster administrators at the admin privilege level.

Description
Create a new subnet.

Parameters

[-ipspace <IPspace>] - IPspace Name
The IPspace to which the new subnet belongs.

-subnet-name <subnet name> - Subnet Name
The name of the subnet to be created. The name of the subnet needs to be unique within the IPspace.

-broadcast-domain <Broadcast Domain> - Broadcast Domain
The broadcast domain to which the new subnet belongs.

-subnet <IP Address/Mask> - Layer 3 Subnet
The address and mask of the subnet.

[-gateway <IP Address>] - Gateway
The gateway of the subnet.

[-ip-ranges (<ipaddr>|<ipaddr>-<ipaddr>), ...] - IP Addresses or IP Address Ranges
The IP ranges associated with this subnet.

[-force-update-lif-associations [true]] - Change the subnet association
This command will fail if any service processor interfaces or network interfaces are using the IP addresses in the ranges provided. Using this parameter will associate any manually addressed interfaces with the subnet and will allow the command to succeed.

Examples
The following examples create subnets named s1 and s6 in IPspace Default.

cluster1::> network subnet add-ranges -ipspace Default -subnet-name s1 -ip-ranges "10.98.1.20-10.98.1.30, 10.98.1.35, 10.98.1.40-10.98.1.49"
network subnet delete

Delete an existing subnet object

Availability: This command is available to cluster administrators at the admin privilege level.

Description
Delete a subnet that contains no ports.

Parameters
- **-ipspace** `<IPspace>` - IPspace Name
  The IPspace to which the subnet belongs.
- **-subnet-name** `<subnet name>` - Subnet Name
  The name of the subnet to be deleted.
- **[-force-update-lif-associations [true]]** - Change the subnet association
  This command will fail if the subnet has ranges containing any existing service processor interface or network interface IP addresses. Setting this value to true will remove the network interface associations with the subnet and allow the command to succeed. However, it will not affect service processor interfaces.

Examples
The following example deletes subnet `s1` in IPspace `Default`.

```
cluster1::> network subnet delete -ipspace Default -subnet-name s1
```

network subnet modify

Modify a layer 3 subnet

Availability: This command is available to cluster administrators at the admin privilege level.

Description
Modify a subnet.

Parameters
- **-ipspace** `<IPspace>` - IPspace Name
  The IPspace to which the subnet belongs.
- **-subnet-name** `<subnet name>` - Subnet Name
  The name of the subnet to modify.
- **[-subnet <IP Address/Mask>]** - Layer 3 Subnet
  The new address and mask of the subnet.
- **[-gateway <IP Address>]** - Gateway
  The new gateway address.
The new IP ranges for this subnet.

[-force-update-lif-associations [true]] - Change the subnet association

This command will fail if any existing service processor interfaces or network interfaces are using IP addresses in the ranges being added. It will also fail if any existing service processor interfaces or network interfaces are using IP addresses in the ranges being removed. Using this parameter will associate the interfaces with the IP addresses in the ranges being added to the subnet. It will also remove the subnet's association with the interfaces with IP addresses in the IP ranges being removed and will allow the command to succeed.

Examples

The following example modifies the subnet address and gateway.

```
cluster1::> network subnet modify -ipspace Default -subnet-name s1 -subnet 192.168.2.0/24 -gateway 192.168.2.1
```

network subnet remove-ranges

Remove address ranges from a subnet

Availability: This command is available to cluster administrators at the admin privilege level.

Description

Remove address ranges from a subnet.

Parameters

-ipspace <IPspace> - IPspace Name

The IPspace in which the range resides.

-subnet-name <subnet name> - Subnet Name

The name of the subnet.

-ip-ranges {<ipaddr>|<ipaddr>-<ipaddr>}, ... - IP Ranges

IP ranges to remove.

[-force-update-lif-associations [true]] - Force Update LIF Associations

This command will fail if any existing service processor interfaces or network interfaces are using IP addresses in the ranges provided. Using this parameter will remove the subnet's association with those interfaces and allow the command to succeed.

Examples

The following example removes an address range with starting address of 10.98.1.1 from subnet s1 in IPspace Default.

```
cluster1::> network subnet remove-ranges -ipspace Default -subnet-name s1 -ip-ranges "10.98.1.1-10.98.1.30"
```

network subnet rename

Rename a layer 3 subnet

Availability: This command is available to cluster administrators at the admin privilege level.
Description
Rename a Subnet.

Parameters
- **-ipspace <IPspace>** - IPspace Name
  - The IPspace to which the subnet belongs.
- **-subnet-name <subnet name>** - Subnet Name
  - The name of the subnet to rename.
- **-new-name <text>** - New Name
  - The new name for the subnet.

Examples
The following example renames subnet *s1* to *s3*.

```
cluster1::> network subnet rename -ipspace Default -subnet s1 -new-name s3
```

**network subnet show**

Display subnet information

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

Description
Display subnet information.

Parameters

[-used-count <integer>] - Used Address Count
Selects the subnets that match the given number of addresses allocated.

[-available-count <integer>] - Available Address Count
Selects the subnets that match the given number of addresses available.

### Examples
The following example displays general information about the subnets.

```
cluster1::> network subnet show
```

<table>
<thead>

### network tcpdump commands
Run tcpdump operations

Network tcpdump commands. The trace files generated during tcpdump packet captures could be located in `/mroot/etc/log/packet_traces/`.

### network tcpdump show
Show running tcpdump instances

**Availability:** This command is available to `cluster` administrators at the `admin` privilege level.

**Description**
The `network tcpdump show` command shows currently running packet traces (via tcpdump) on a matching node.

**Parameters**

```
[-fields <fieldname>, ...]
```
If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

```
[-instance]
```
If you specify the `-instance` parameter, the command displays detailed information about all fields.

```
[-node <nodename> | local] - Node Name
```
Use this parameter optionally to show the details of running packet traces on a matching node.

```
[-port <netport> | <ifgrp>] - Port
```
Use this parameter optionally to show the details of running packet trace on a matching network interface.

### Examples
The following example shows the details of running packet traces on nodes "node1" and "node2":

```
416
```
network tcpdump start

tcpdump start

*Availability:* This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

**Description**
The `network tcpdump start` command starts packet tracing (via tcpdump) with the given parameters.

**Parameters**
- `-node <nodename>|local` - **Node Name**
  Use this parameter to specify the node on which the packet trace should run.
- `-port <netport>|<ifgrp>` - **Port**
  Use this parameter to specify the network interface for packet tracing.
- `[-address <IP Address>]` - **IP Address**
  Use this parameter to optionally specify the address for packet tracing.
- `[-protocol-port <integer>]` - **Protocol Port Number**
  Use this parameter to optionally specify the protocol port number for packet tracing.
- `[-buffer-size <integer>]` - **Buffer Size in KB**
  Use this parameter to optionally specify the buffer size for packet tracing. The default buffer size is 4 KB.
- `[-file-size <integer>]` - **Trace File Size in MB**
  Use this parameter to optionally specify the trace file size for packet tracing. The default trace file size is 1 GB.
- `[-rolling-traces <integer>]` - **Number of Rolling Trace Files**
  Use this parameter to optionally specify the number of rolling trace files for packet tracing. The default number of rolling trace files is 2.

**Examples**
The following example starts packet tracing on node "node1" with address "10.98.16.164", network interface "e0c", buffer size "10 KB", and protocol port number "10000":

```
cluster1::> network tcpdump start -node node1
            -address 10.98.16.164 -port e0c -buffer-size 10 -protocol-port 10000
```

network tcpdump stop

Stop an active tcpdump trace

*Availability:* This command is available to *cluster* administrators at the *admin* privilege level.
The `network tcpdump stop` command stops a running packet trace (via tcpdump) on a given network interface. The trace files could be located in `/mroot/etc/log/packet_traces/`.

**Parameters**

- `node (<nodename> | local)` - Node Name
  
  Use this parameter to specify the node on which the packet tracing must be stopped.

- `port (<netport> | <ifgrp>)` - Port
  
  Use this parameter to specify the network interface on which the packet tracing must be stopped.

**Examples**

The following example stops a packet trace on network interface "e0a" from node "node1":

```
cluster1::> network tcpdump stop -node node1 -port e0a
```

### network tcpdump trace commands

The trace directory

Network tcpdump trace commands.

### network tcpdump trace delete

Delete a tcpdump trace file

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**

The `network tcpdump trace delete` command deletes the tcpdump trace file from a matching node.

**Parameters**

- `node (<nodename> | local)` - Node Name
  
  Use this parameter to delete the tcpdump trace file from a matching node.

- `trace-file <text>` - Trace File
  
  Use this parameter to specify the tcpdump trace file to be deleted.

**Examples**

The following example deletes the list of tcpdump trace files from node "node1" using wildcard pattern:

```
cluster1::> network tcpdump trace delete -node node1 -trace-file *
```

### network tcpdump trace show

Show list of tcpdump trace files

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**

The `network tcpdump trace show` command shows the list of tcpdump trace files. The trace files could be located in `/mroot/etc/log/packet_traces/`. 
Parameters

{{-fields <fieldname>, ...}]

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

|[-instance ]]}

If you specify the `-instance` parameter, the command displays detailed information about all fields.

[-node \{<nodename>|local\}] - Node Name

Use this parameter to show the list of traces files of a matching node.

[-trace-file <text>] - Trace File

Use this parameter optionally to show the list of trace files with a matching trace-file name.

Examples

The following example shows the list of trace files on nodes "node1" and "node2":

<table>
<thead>
<tr>
<th>node1</th>
<th>node2</th>
</tr>
</thead>
<tbody>
<tr>
<td>e0a_20170314_115624.trc0</td>
<td>e0c_20170314_115624.trc0</td>
</tr>
</tbody>
</table>

network test-link commands

The test-link directory

network test-link run-test

Test link bandwidth

Availability: This command is available to cluster administrators at the advanced privilege level.

Description

The `network test-link run-test` command runs a performance test between two nodes. The command requires a source node, Vserver, and destination address.

Before executing the `network test-link run-test` command, the `network test-link start-server` command must be run to start a server on the node hosting the destination LIF. After all tests to that node are complete the `network test-link stop-server` command must be run to stop the server.

The test results are stored non-persistently and can be viewed using the `network test-link show` command. Results include input parameters, the bandwidth achieved, and the date and time of the test.

Parameters

- `-node \{<nodename>|local\} - Node Name`
  
  Use this parameter to specify the node which initiates the test.

- `-vserver <vserver> - Vserver`
  
  Use this parameter to specify the Vserver to access the destination LIF. DC (Data Channel) Vserver option is available only in an ONTAP Select or ONTAP Cloud cluster. It is a special vserver that hosts LIFs that are used to mirror data aggregates to partner node.
-destination <Remote InetAddress> - Destination

Use this parameter to specify the destination IP address.

**Examples**

The following example runs a test between the cluster LIFs, including the start and stop of the server side of the test:

```
cluster1::*> network test-link start-server -node node1
cluster1::*> network test-link run-test -node node2 -vserver Cluster -destination 172.31.112.173
   Node: node2
   Vserver: Cluster
   Destination: 172.31.112.173
   Time of Test: 4/22/2016 15:33:18
   MB/s: 41.2678
cluster1::*> network test-link stop-server -node node1
cluster1::*> network test-link show
```

<table>
<thead>
<tr>
<th>Node</th>
<th>Vserver</th>
<th>Destination</th>
<th>Time of Test</th>
<th>MB/s</th>
</tr>
</thead>
<tbody>
<tr>
<td>node2</td>
<td>Cluster</td>
<td>172.31.112.173</td>
<td>4/22/2016 15:33:18</td>
<td>41.2678</td>
</tr>
</tbody>
</table>

**network test-link show**

Display test results

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

**Description**

The `network test-link show` command displays the results of prior `network test-link run-test` commands. The test results are stored non-persistently and can be viewed using the `network test-link show` command. Results include input parameters, the bandwidth achieved, and the date and time of the test.

**Parameters**

```bash
[-fields <fieldname>, ...]
```

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

```bash
[-instance]
```

If you specify the `-instance` parameter, the command displays detailed information about all fields.

```bash
-node (<nodename>|local) - Node
```

Selects the nodes that match this parameter value. Use this parameter to display the test results specific to a node. By default, the test results across all nodes are shown.
-vserver <vserver> - Vserver

Use this parameter to display the test results specific to a Vserver. Use DC (Data Channel) Vserver option only in an ONTAP Select or ONTAP Cloud cluster to show network performance of links hosting DC LIFs. DC Vserver is a special Vserver that hosts LIFs that are used to mirror data aggregates to partner node.

[-destination <Remote InetAddress>] - Destination

Use this parameter to display the test results associated with the specified destination.

[-timestamp <MM/DD/YYYY HH:MM:SS>] - Time of Test

Use this parameter to display the test results with the specified timestamp.

[-bandwidth <double>] - MB/s

Use this parameter to display the test results only matching the specified bandwidth.

Examples

The following example runs a test between the cluster LIFs twice and then demonstrates the show command results:

```
cluster1::*> network test-link run-test -node node2 -vserver Cluster -destination 172.31.112.173

  Node: node2
  Vserver: Cluster
  Destination: 172.31.112.173
  Time of Test: 4/25/2016 10:37:52
  MB/s: 29.9946

cluster1::*> network test-link run-test -node node2 -vserver Cluster -destination 172.31.112.173

  Node: node2
  Vserver: Cluster
  Destination: 172.31.112.173
  Time of Test: 4/25/2016 10:38:32
  MB/s: 39.8192
```

```
cluster1::network test-link*> show

     Node    Vserver Destination  Time of Test        MB/s
-----------------  -----------------  ---------------  -------------------  -------------
```

network test-link start-server

Start server for bandwidth test

Availability: This command is available to cluster administrators at the advanced privilege level.

Description

The network test-link start-server command starts the server side of the network test-link test on the designated node.

Only one server at a time can be running for the network test-link command on a given node. If the network test-link start-server command is issued and a server is already running on the node, then the command is ignored, and the existing server continues to run.

network test-link commands 421
The server started is listening on port 5201.

**Parameters**
- `node {<nodename>|local}` - Node Name
  
  Use this parameter to specify the node where the server is to be started.

**Examples**

The following example starts a server:

```
cluster1::*> network test-link start-server -node node1
```

**network test-link stop-server**

Stop server for bandwidth test

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

**Description**

The `network test-link stop-server` command stops the `network test-link` server running on the designated node.

**Parameters**
- `node {<nodename>|local}` - Node Name
  
  Use this parameter to specify the node where the server is to be stopped.

**Examples**

The following example starts a server and stops it:

```
cluster1::*> network test-link start-server -node node1
cluster1::*> network test-link stop-server -node node1
```

network tuning commands
Manage network tuning options

network tuning icmp commands
Manage ICMP tuning setting

network tuning icmp modify
Modify ICMP tuning options

Availability: This command is available to cluster administrators at the admin privilege level.

Description
This command displays options which can be used to fine tune icmp protocol behavior.

Parameters

- `-node {<nodename>|local}` - Node
  Sets this parameter to indicate on which node the ICMP tuning options are modified.

- `-is-drop-redirect-enabled {true|false}` - Drop redirect ICMP
  Sets this parameter to drop redirect ICMP message.

- `-tx-icmp-limit <integer>` - Maximum number of ICMP packets sent per second
  Sets the maximum number of ICMP messages including TCP RSTs can be sent per second.

- `-redirect-timeout <integer>` - Maximum seconds for route redirect timeout
  Sets this parameter to indicate the number of seconds after which the route is deleted. Value of zero means infinity. The default value is 300 seconds.

Examples
cluster1::> network tuning icmp modify -node node1 -is-drop-redirect-enabled false

network tuning icmp show
Show ICMP tuning options

Availability: This command is available to cluster administrators at the admin privilege level.

Description
This command displays the current state of the ICMP tuning options for the given node.

Parameters

{ [-fields <fieldname>, ...]

  If you specify the `fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

  | [-instance ]

  Displays all ICMP tuning options.}
[-node \{<nodename>|local\}] - Node
   Specifies the node for which the ICMP tuning options are displayed.
[-is-drop-redirect-enabled \{true|false\}] - Drop redirect ICMP
   Displays all entries that match the "is-drop-redirect-enabled" value.
[-tx-icmp-limit <integer>] - Maximum number of ICMP packets sent per second
   Displays all entries that match the "tx-icmp-limit" value.
[-redirect-timeout <integer>] - Maximum seconds for route redirect timeout
   Displays all the entries that match the "redirect-timeout" value.

Examples

\begin{verbatim}
cluster1::> network tuning icmp show
\end{verbatim}

<table>
<thead>
<tr>
<th>Node</th>
<th>Drop Redirect</th>
<th>Maximum ICMP Sends per Second</th>
<th>Redirect Timeout in Seconds</th>
</tr>
</thead>
<tbody>
<tr>
<td>node1</td>
<td>true</td>
<td>100</td>
<td>300</td>
</tr>
</tbody>
</table>

network tuning icmp6 commands

Manage ICMPv6 tuning setting

network tuning icmp6 modify

Modify ICMPv6 tuning options

Availability: This command is available to cluster administrators at the admin privilege level.

Description
This command displays options which can be used to fine tune icmpv6 protocol behavior.

Parameters
- \{-node \{<nodename>|local\} - Node
   Sets this parameter to indicate on which node the ICMPv6 tuning options are modified.
- [-is-v6-redirect-accepted \{true|false\}] - Accept redirects via ICMPv6
   Sets this parameter to indicate whether or not redirect ICMPv6 messages are accepted.
- [-redirect-v6-timeout <integer>] - Maximum seconds for route redirect timeout
   Sets this parameter to indicate the number of seconds after which the route is deleted. Value of zero means infinity. The default value is 300 seconds.

Examples

\begin{verbatim}
cluster1::> network tuning icmp6 modify -node node1 -is-v6-redirect-accepted false
\end{verbatim}

network tuning icmp6 show

Show ICMPv6 tuning options

Availability: This command is available to cluster administrators at the admin privilege level.
Description
This command displays the current state of the ICMPv6 tuning options for the given node.

Parameters
{-fields <fieldname>,...}
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified
field or fields. You can use `-fields ?' to display the fields to specify.

[-instance }
Displays all ICMPv6 tuning options.

[-node {<nodename>|local}] - Node
Specifies the node for which the ICMPv6 tuning options are displayed.

[-is-v6-redirect-accepted {true|false}] - Accept redirects via ICMPv6
Displays all entries that match the "is-v6-redirect-accepted" value.

[-redirect-v6-timeout <integer>] - Maximum seconds for route redirect timeout
Displays all the entries that match the "redirect-v6-timeout" value.

Examples

```
cluster1::> network tuning icmp6 show
          Accept Redirect Redirect Timeout
          ICMPv6 in Seconds
          --------- --------------- ----------------
        node1       true        300
```

network tuning tcp commands
Manage TCP tuning setting

network tuning tcp modify
Modify TCP tuning options

Availability: This command is available to cluster administrators at the admin privilege level.

Description
This commands sets TCP tuning options on the node.

Parameters
-node {<nodename>|local} - Node
Indicates on which node the TCP tuning options will be modified.

[-is-path-mtu-discovery-enabled {true|false}] - Path MTU discovery enabled
Enables path MTU discovery feature.

[-is-rfc3465-enabled {true|false}] - RFC3465 enabled
Enables the rfc3465 feature.

[-max-cwnd-increment <integer>] - Maximum congestion window segments incrementation
Sets the maximum congestion window increment segements during slow start.
[-is-rfc3390-enabled (true|false)] - RFC3390 enabled
   Enables the rfc3390 feature.

[-is-sack-enabled (true|false)] - SACK support enabled
   Enables the selective ACK feature.

Examples

    cluster1::> network tuning tcp modify -node node1 -is-path-mtu-discovery-enabled false

network tuning tcp show

Show TCP tuning options

Availability: This command is available to cluster administrators at the admin privilege level.

Description

This command displays the current state of the TCP tuning options for the given node.

Parameters

[-fields <fieldname>, ...]
   If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified
   field or fields. You can use '-fields ?' to display the fields to specify.

[-instance]
   Displays all TCP tuning options.

[-node (<nodename>|local)] - Node
   Specifies the node for which the TCP tuning options will be displayed.

[-is-path-mtu-discovery-enabled (true|false)] - Path MTU discovery enabled
   Displays all entries that match the "is-path-mtu-discovery-enabled" value.

[-is-rfc3465-enabled (true|false)] - RFC3465 enabled
   Displays all entries that match the "is-rfc3465-enabled" value.

[-max-cwnd-increment <integer>] - Maximum congestion window segments incrementation
   Displays all entries that match the "max-cwnd-increment" value.

[-is-rfc3390-enabled (true|false)] - RFC3390 enabled
   Displays all entries that match the "is-rfc3390-enabled" value.

[-is-sack-enabled (true|false)] - SACK support enabled
   Displays all entries that match the "is-sack-enabled" value.

Examples

    cluster1::> network tuning tcp show
    Path MTU       Maximum                   Selective
    Node  Discovery RFC3465 Congestion Window RFC3390 Ack
    --------- ---------  ------- ----------------- ------- --------
    node1   true       true    2                 true    true

426 Commands: Manual Page Reference
**protection-type commands**

Manage Protection Types and RPOs

**protection-type show**

Display the supported protection types and available RPOs

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *advanced* privilege level.

**Description**
This command displays the protection types available for application provisioning.

**Parameters**

- `{ -fields <fieldname>, ... }`  
  Specifies fields that you want included in the output. You can use `-fields ?` to display the available fields.

- `{ -instance }`  
  Specifies the display of all available fields for each selected protection type.

- `[-vserver <vserver name>] - Vserver`  
  Selects the protection types of Vservers that match the parameter value.

- `[-protection-type {local|remote}] - Protection Type`  
  Selects the protection types that match the parameter value.

- `[-rpo-list <text>, ...] - List of available RPOs`  
  Selects the protection types whose list of available RPOs matches the parameter value.

- `[-rpo-list-description <text>, ...] - List of descriptions of available RPOs`  
  Selects the protection types whose list of description of available RPOs matches the parameter value.

- `[-description <text>] - Description of Protection Type`  
  Selects the protection types with a description that matches the parameter value.

**Examples**

The following example displays the protection types and the associated available RPOs for all Vservers in the cluster.

```
cluster1::*> protection-type show
Vserver Protection Type RPO List
-------------- -------------------
vs1            local       hourly, none
               remote      none
vs2            local       hourly, none
               remote      none, zero
```

**qos commands**

QoS settings
qos adaptive-policy-group commands

The adaptive-policy-group directory

qos adaptive-policy-group create

Create an adaptive policy group

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The qos adaptive-policy-group create command creates a new adaptive policy group. After the adaptive policy group is created, you can assign one or more storage objects to the policy. When a storage object is assigned to an adaptive policy group, the maximum throughput QoS setting automatically adjusts based on the storage object used space or the storage object allocated space. QoS minimum throughput setting is calculated from the expected-iops parameter and the storage object allocated size. It is set only for the storage objects that reside on AFF platforms.

After you create an adaptive policy group, use the storage object create command or storage object modify command to apply the adaptive policy group to a storage object.

Parameters
- `policy-group <text>` - Name
  Specifies the name of the adaptive policy group. Adaptive policy group names must be unique and are restricted to 127 alphanumeric characters including underscores "_" and hyphens ":". Adaptive policy group names must start with an alphanumeric character. Use the qos adaptive-policy-group rename command to change the adaptive policy group name.

- `vserver <vserver name>` - Vserver
  Specifies the data Vserver to which this adaptive policy group belongs to. You can apply this adaptive policy group to only the storage objects contained in the specified Vserver. If the system has only one Vserver, then the command uses that Vserver by default.

- `expected-iops <integer>[IOPS[/{GB|TB}]] (default: TB)` - Expected IOPS
  Specifies the minimum expected IOPS per TB or GB allocated based on the storage object allocated size.

- `peak-iops <integer>[IOPS[/{GB|TB}]] (default: TB)` - Peak IOPS
  Specifies the maximum possible IOPS per TB or GB allocated based on the storage object allocated size or the storage object used size.

[-`absolute-min-iops <qos_tput>`] - Absolute Minimum IOPS
  Specifies the absolute minimum IOPS which is used as an override when the expected IOPS is less than this value. The default value is computed as follows:
  
  \[ \text{if expected-iops} \geq 6144/\text{TB, then absolute-min-iops} = 1000\text{IOPS}; \text{if expected-iops} \geq 2048/\text{TB and expected-iops} < 6144/\text{TB, then absolute-min-iops} = 500\text{IOPS}; \text{if expected-iops} \geq 1/\text{MB and expected-iops} < 2048/\text{TB, then absolute-min-iops} = 75\text{IOPS}. \]

[-`expected-iops-allocation {used-space|allocated-space}`] - Expected IOPS Allocation
  Specifies the expected IOPS allocation policy. The allocation policy is either allocated-space or used-space. When the expected-iops-allocation policy is set to allocated-space, the expected IOPS is calculated based on the size of the storage object. When the expected-iops-allocation policy is set to used-space, the expected IOPS is calculated based on the amount of data stored in the storage object taking into account storage efficiencies. The default value is allocated-space.
[---peak-iops-allocation (used-space|allocated-space)] - Peak IOPS Allocation

Specifies the peak IOPS allocation policy. The allocation policy is either allocated-space or used-space. When the peak-iops-allocation policy is set to allocated-space, the peak IOPS is calculated based on the size of the storage object. When the peak-iops-allocation policy is set to used-space, the peak IOPS is calculated based on the amount of data stored in the storage object taking into account storage efficiencies. The default value is used-space.

[---block-size {ANY|4K|8K|16K|32K|64K|128K}] - Block Size

Specifies the I/O block size for the QoS adaptive policy group. The default value is "ANY". When block-size of "ANY" is specified, then control is by IOPS. When block-size other than "ANY" is specified, then control is by IOPS and bytes per second(bps). bps is the product of IOPS and block-size.

Examples

cluster1::> qos adaptive-policy-group create p1 -vserver vs1 -expected-iops 100IOPS/TB -peak-iops 1000IOPS/TB

Creates the "p1" adaptive policy group which belongs to Vserver "vs1" with expected-iops of 100IOPS/TB and peak-iops of 1000IOPS/TB with default value for absolute-min-iops

Related references

qos adaptive-policy-group rename on page 431

qos adaptive-policy-group delete

Delete an adaptive policy group

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The qos adaptive-policy-group delete command deletes an adaptive policy group from a cluster. You cannot delete a policy group if a QoS workload associated with a storage object is assigned to it unless you use the -force parameter. Using the -force parameter will delete all the QoS workloads for storage objects associated with the specified adaptive policy groups.

Only user created adaptive policy groups can be deleted. Default adaptive policy groups are read only and cannot be deleted.

Parameters

-policy-group <text> - Name

Specifies the name of the adaptive policy group that you want to delete.

[-force [true]] - Force Delete Workloads for the QoS adaptive policy group (privilege: advanced)

Specifies whether to delete an adaptive policy group along with any underlying workloads.

Examples

The following example deletes "p1" adaptive policy group:

cluster1::> qos adaptive-policy-group delete p1

Deletes the "p1" adaptive policy group along with any underlying QoS workloads.
qos adaptive-policy-group modify

Modify an adaptive policy group

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The qos adaptive-policy-group modify command modifies an adaptive policy group.

Only user-created adaptive policy groups can be modified. Default adaptive policy groups are read-only and cannot be modified.

Parameters

-policy-group <text> - Name

Specifies the name of the adaptive policy group. Adaptive policy group names must be unique and are restricted to 127 alphanumeric characters including underscores "_" and hyphens "-". Adaptive policy group names must start with an alphanumeric character. Use the qos adaptive-policy-group rename command to change the adaptive policy group name.

[expected-iops {<integer>[IOPS/[GB|TB]]} (default: TB)] - Expected IOPS

Specifies the minimum expected IOPS per TB or GB allocated based on the storage object allocated size. QoS minimum throughput setting is calculated from the expected-iops parameter. It is set only for the storage objects that reside on AFF platforms.

[peak-iops {<integer>[IOPS/[GB|TB]]} (default: TB)] - Peak IOPS

Specifies the maximum possible IOPS per TB or GB allocated based on the storage object allocated size or the storage object used size.

[absolute-min-iops <qos_tput>] - Absolute Minimum IOPS

Specifies the absolute minimum IOPS which is used as an override when the expected IOPS is less than this value. The default value is computed as follows:

if expected-iops >= 6144/TB, then absolute-min-iops = 1000IOPS;
if expected-iops >= 2048/TB and expected-iops < 6144/TB, then absolute-min-iops = 500IOPS;
if expected-iops >= 1/MB and expected-iops < 2048/TB, then absolute-min-iops = 75IOPS.

[expected-iops-allocation {used-space|allocated-space}] - Expected IOPS Allocation

Specifies the expected IOPS allocation policy. The allocation policy is either allocated-space or used-space. When the expected-iops-allocation policy is set to allocated-space, the expected IOPS is calculated based on the size of the storage object. When the expected-iops-allocation policy is set to used-space, the expected IOPS is calculated based on the amount of data stored in the storage object taking into account storage efficiencies. The default value is allocated-space.

[peak-iops-allocation {used-space|allocated-space}] - Peak IOPS Allocation

Specifies the peak IOPS allocation policy. The allocation policy is either allocated-space or used-space. When the peak-iops-allocation policy is set to allocated-space, the peak IOPS is calculated based on the size of the storage object. When the peak-iops-allocation policy is set to used-space, the peak IOPS is calculated based on the amount of data stored in the storage object taking into account storage efficiencies. The default value is used-space.

[block-size {ANY|4K|8K|16K|32K|64K|128K}] - Block Size

Specifies the I/O block size for the QoS adaptive policy group. The default value is "ANY". When block-size of "ANY" is specified, then control is by IOPS. When block-size other than "ANY" is specified, then control is by IOPS and bytes per second(bps). bps is the product of IOPS and block-size.
Examples
The following example modifies the "p1" adaptive policy group with specified values.

```
cluster1::> qos adaptive-policy-group modify -policy-group p1
               -expected-iops 200IOPS/TB -peak-iops 2000IOPS/TB
               -absolute-min-iops 100IOPS
```

Related references
- qos adaptive-policy-group rename on page 431

**qos adaptive-policy-group rename**

Rename an adaptive policy group

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**
The qos adaptive-policy-group rename command changes the name of an existing adaptive policy group.

**Parameters**

- **-policy-group <text>** - Name
  Specifies the existing name of the adaptive policy group that you want to rename.

- **-new-name <text>** - New adaptive policy group name
  Specifies the new name of the adaptive policy group. Adaptive policy group names must be unique and are restricted to 127 alphanumeric characters including underscores "_" and hyphens "-". Adaptive policy group names must start with an alphanumeric character.

Examples
```
cluster1::> qos adaptive-policy-group rename -policy-group p1 -new-name p1_new
```

**qos adaptive-policy-group show**

Display a list of adaptive policy groups

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**
The qos adaptive-policy-group show command shows the current settings of the adaptive policy groups on a cluster. You can view the list of adaptive policy groups and also the detailed information about a specific adaptive policy group.

**Parameters**

```
{ [-fields <fieldname>, ...]
              If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields?' to display the fields to specify.

   [-instance ]
              If you specify the -instance parameter, the command displays detailed information about all fields.

   [-policy-group <text>] - Name
              Selects the adaptive policy groups that match this parameter value.
```

qos adaptive-policy-group commands
Adaptive policy groups define measurable service level objectives (SLOs) that adjust based on the storage object used space or the storage object allocated space.

```
[-vserver <vserver name>] - Vserver
If this parameter is specified, the command displays information only about the adaptive policy groups with a matching vserver.
```

```
[-uuid <UUID>] - Uuid
If this parameter is specified, the command displays information only about the adaptive policy groups with the specified UUID.
```

```
[-pgid <integer>] - ID
If this parameter is specified, the command displays information only about the adaptive policy groups that match the given policy group ID, which is an integer that uniquely identifies the adaptive policy group.
```

```
[-expected-iops (<integer>[IOPS/[GB|TB]]) (default: TB)] - Expected IOPS
If this parameter is specified, the command displays information only about the adaptive policy groups with the specified minimum expected IOPS per TB or GB.
```

```
[-peak-iops (<integer>[IOPS/[GB|TB]]) (default: TB)] - Peak IOPS
If this parameter is specified, the command displays information only about the adaptive policy groups with the specified maximum possible IOPS per TB or GB.
```

```
[-absolute-min-iops <qos_tput>] - Absolute Minimum IOPS
If this parameter is specified, the command displays information only about the adaptive policy groups with the specified absolute minimum IOPS.
```

```
[-expected-iops-allocation {used-space|allocated-space}] - Expected IOPS Allocation
If this parameter is specified, the command displays information only about the adaptive policy groups with the specified expected IOPS allocation policy used to compute the expected IOPS per TB or GB.
```

```
[-peak-iops-allocation {used-space|allocated-space}] - Peak IOPS Allocation
If this parameter is specified, the command displays information only about the adaptive policy groups with the specified peak IOPS allocation policy used to compute the maximum possible IOPS per TB or GB.
```

```
[-block-size {ANY|4K|8K|16K|32K|64K|128K}] - Block Size
Specifies the I/O block size for the QoS adaptive policy group. The default value is "ANY". When block-size of "ANY" is specified, then control is by IOPS. When block-size other than "ANY" is specified, then control is by IOPS and bytes per second(bps). bps is the product of IOPS and block-size.
```

```
[-num-workloads <integer>] - Number of Workloads
If this parameter is specified, the command displays information only about the adaptive policy groups with the specified number of workloads.
```

### Examples

The example above displays all adaptive policy groups on the cluster.

```
cluster1::> qos adaptive-policy-group show
qos adaptive-policy-group show

Commands: Manual Page Reference
qos policy-group commands

The policy-group directory

qos policy-group create

Create a policy group

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The qos policy-group create command creates a new policy group. You can use a QoS policy group to control a set of storage objects known as "workloads" - LUNs, volumes, files, or Vservers. Policy groups define measurable service level objectives (SLOs) that apply to the storage objects with which the policy group is associated.

After you create a policy group, you use the storage object create command or the storage object modify command to apply the policy group to a storage object.

Parameters

-policy-group <text> - Policy Group Name

Specifies the name of the policy group. Policy group names must be unique and are restricted to 127 alphanumeric characters including underscores "_" and hyphens ":". Policy group names must start with an alphanumeric character. You use the qos policy-group rename command to change the policy group name.

-vserver <vserver name> - Vserver

Specifies the data Vserver to which this policy group belongs. You can apply this policy group to only the storage objects contained in the specified Vserver. For example, if you want to apply this policy group to a volume, that volume must belong to the specified Vserver. Using this parameter does not apply the policy group's SLOs to the Vserver. You need to use the vserver modify command if you want to apply this policy group to the Vserver. If the system has only one Vserver, then the command uses that Vserver by default.

-max-throughput <qos_tput> - Maximum Throughput

Specifies the maximum throughput for the policy group. A maximum throughput limit specifies the throughput that the policy group must not exceed. It is specified in terms of IOPS or MB/s, or a combination of comma separated IOPS and MB/s. The range is one to infinity. A value of zero is accepted but is internally treated as infinity.

The values entered here are case-insensitive, and the units are base ten. There should be no space between the number and the units. The default value for max-throughput is infinity, which can be specified by the special value "INF". Note that there is no default unit - all numbers except zero require explicit specification of the units.

Two reserved keywords, "none" and "INF", are available for the situation that requires removal of a value, and the situation that needs to specify the maximum available value.

Examples of valid throughput specifications are: "100B/s", "10KB/s", "1gb/s", "500MB/s", "1tb/s", "100iops", "100iops,400KB/s", and "800KB/s,100iops"
[-min-throughput <qos_tput>] - Minimum Throughput
Specifies the minimum throughput for the policy group. A minimum throughput specifies the desired performance level for a policy group. It is specified in terms of IOPS.
The values entered here are case-insensitive, and the units are base ten. There should be no space between the number and the units. The default value for min-throughput is "0". The default unit is IOPS.
One reserved keyword, 'none' is available for the situation that requires removal of a value.
Examples of valid throughput specifications are: "100iops" and "100".

[-is-shared {true|false}] - Is Shared
Specifies whether the policy group can be shared or not. The default value is "true". This parameter specifies if the SLOs of the policy group are shared between the workloads or if the SLOs are applied separately to each workload.

Examples

```
cluster1::> qos policy-group create p1 -vserver vs1
```

Creates the "p1" policy group which belongs to Vserver "vs1" with default policy values.

```
cluster1::> qos policy-group create p2 -vserver vs1 -max-throughput 500MB/s
```

Creates the "p2" policy group which belongs to Vserver "vs1" with the maximum throughput set to 500 MB/s.

```
cluster1::> qos policy-group create p3 -vserver vs1 -max-throughput 500MB/s -is-shared false
```

Related references

-qos policy-group rename on page 435

qos policy-group delete
Delete an existing QoS Policy Group
Availability: This command is available to cluster administrators at the admin privilege level.

Description
The qos policy-group delete command deletes a policy group from a cluster. You cannot delete a policy group if a qos workload associated with storage object is assigned to it unless you use "-force". Using "-force" will delete all the qos workloads for storage objects associated with the specified policy groups.
You can only delete user-defined policy groups. You cannot delete preset policy groups.

Parameters
-policy-group <text> - Policy Group Name
Specifies the name of the policy group that you want to delete.

-[force [true]] - Force Delete Workloads for the QoS Policy Group (privilege: advanced)
Specifies whether to delete a policy group along with any underlying workloads.

Examples

```
cluster1::> qos policy-group delete p1
```
qos policy-group modify

Modify a policy group

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The qos policy-group modify command modifies a user-created policy group.

Parameters
-policy-group <text> - Policy Group Name

Specifies the name of the policy group that you want to modify.

[-max-throughput <qos_tput>] - Maximum Throughput

Specifies the maximum throughput for the policy group. A maximum throughput limit specifies the throughput that the policy group must not exceed. It is specified in terms of IOPS or MB/s, or a combination of comma separated IOPS and MB/s. The range is one to infinity. A value of zero is accepted but is internally treated as infinity.

The values entered here are case-insensitive, and the units are base ten. There should be no space between the number and the units. The default value for max-throughput is infinity, which can be specified by the special value "INF". Note there is no default unit - all numbers except zero require explicit specification of the units.

Two reserved keywords, "none" and "INF", are available for the situation that requires removal of a value, and the situation that needs to specify the maximum available value.

Examples of valid throughput specifications are: "100B/s", "10KB/s", "1gb/s", "500MB/s", "1tb/s", and "100iops".

[-min-throughput <qos_tput>] - Minimum Throughput

Specifies the minimum throughput for the policy group. A minimum throughput specifies the desired performance level for a policy group. It is specified in terms of IOPS.

The values entered here are case-insensitive, and the units are base ten. There should be no space between the number and the units. The default value for min-throughput is "0". The default unit is IOPS.

One reserved keyword, 'none' is available for the situation that requires removal of a value.

Examples of valid throughput specifications are: "100iops" and "100".

Examples

cluster1::> qos policy-group modify p1 -max-throughput 10IOPS

qos policy-group rename

Rename a policy group

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The qos policy-group rename command changes the name of an existing policy group.
Parameters

-policy-group <text> - Policy Group Name
   Specifies the existing name of the policy group that you want to rename.

-new-name <text> - New Policy Group Name
   Specifies the new name of the policy group. Policy group names must be unique and are restricted to 127
   alphanumeric characters including underscores "_" and hyphens "-". Policy group names must start with an
   alphanumeric character.

Examples

cluster1::> qos policy-group rename -policy-group p1 -new-name p1_new

qos policy-group show

Display a list of policy groups

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The qos policy-group show command shows the current settings of the policy groups on a cluster. You can display a list of
the policy groups and you can view detailed information about a specific policy group.

Parameters

{ [-fields <fieldname>, ...]
   If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified
   field or fields. You can use '-fields ?' to display the fields to specify.

| [-instance ]
   If you specify the -instance parameter, the command displays detailed information about all fields.

[-policy-group <text>] - Policy Group Name
   Selects the policy groups that match this parameter value
   Policy groups define measurable service level objectives (SLOs) that apply to the storage objects with which
   the policy group is associated.

[-vserver <vserver name>] - Vserver
   Selects the policy groups that match this parameter value

[-uuid <UUID>] - Uuid
   Selects the policy groups that match this parameter value

[-class <QoS Configuration Class>] - Policy Group Class
   Selects the policy groups that match this parameter value

[-pgid <integer>] - Policy Group ID
   Selects the policy groups that match this parameter value
   This uniquely identifies the policy group

[-max-throughput <qos_tput>] - Maximum Throughput
   Selects the policy groups that match this parameter value
   A maximum throughput limit specifies the throughput (in IOPS or MB/s) that the policy group must not exceed.
[-min-throughput <qos_tput>] - Minimum Throughput
Selects the policy groups that match this parameter value.
A minimum throughput specifies the desired performance level for a policy group.

[-num-workloads <integer>] - Number of Workloads
Selects the policy groups that match this parameter value.

[-throughput-policy <text>] - Throughput Policy
Selects the policy groups that match this parameter value. You can specify the throughput range in terms of IOPS or data rate. For example, 0-1INF, 0-400IOPS, 0-200KB/s, 0-400MB/s.

[-is-shared {true|false}] - Is Shared
Selects the policy groups that match this parameter value.
The shared value specifies whether the policy group is a shared policy group or not.

[-is-auto-generated {true|false}] - Is Policy Auto Generated
Selects the policy groups that match this parameter value.
The auto-generated value specifies whether the policy group is an automatically generated policy group or not.

qos settings commands

QoS settings

qos settings cache commands

Cache QoS settings

qos settings cache modify

Modify the cache policy

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The qos settings cache modify command modifies the existing default caching-policy. The list of caching policies can be obtained from the qos setting cache show -fields cache-setting command.
Parameters

-cache-setting <text> - Cache Policy Name

Valid inputs to this parameter include any one of the listed caching-policies. This command is to be used together with the default parameter. If you use this parameter, the command modifies the specified caching-policy based on the default parameter.

[-default (true|false)] - Is Default?

Valid inputs to this parameter are true and false. Together with cache-setting, this parameter helps set or unset a caching-policy as default.

Examples

```
cluster1::> qos settings cache modify -default true -cache-setting random_read_write-random_write
```

qos settings cache show

Display list of cache policies

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The `qos settings cache show` shows the current caching-policies, class to which they belong, the number of workloads associated with each of the policies, and whether or not they are set to default. The following external-cache policies are available:

- none - Does not cache any user data or metadata blocks.
- auto - Read caches all metadata and randomly read user data blocks, and write caches all randomly overwritten user data blocks.
- all - Read caches all data blocks read and written. It does not do any write caching.
- all-random_write - Read caches all data blocks read and written. It also write caches randomly overwritten user data blocks.
- all_read - Read caches all metadata, randomly read, and sequentially read user data blocks.
- all_read-random_write - Read caches all metadata, randomly read, and sequentially read user data blocks. It also write caches randomly overwritten user data blocks.
- all_read_random_write - Read caches all metadata, randomly read, sequentially read and randomly written user data. It also write caches randomly overwritten user data blocks.
- all_read_random_write-random_write - Read caches all metadata, randomly read, sequentially read, and randomly written user data blocks. It also write caches randomly overwritten user data blocks.
- all_read_random_write - Read caches all metadata and write caches randomly overwritten user data blocks.
- meta - Read caches only metadata blocks.
- meta-random_write - Read caches all metadata and write caches randomly overwritten user data blocks.
- noread-random_write - Write caches all randomly overwritten user data blocks. It does not do any read caching.
- random_read - Read caches all metadata and randomly read user data blocks.
- random_read_write - Read caches all metadata, randomly read and randomly written user data blocks.
- random_read_write-random_write - Read caches all metadata, randomly read, and randomly written user data blocks. It also write caches randomly overwritten user data blocks.

Note: Note that in a caching-policy name, a hyphen (\-) separates read and write caching policies.
Parameters
{[-fields <fieldname>, ...]}
   The input to this parameter is one of the following: {cache-setting|class|default|num-workloads}. If you use this parameter, the command displays information related to the specified input field.

{[-instance]}
   If you use this parameter, the command displays information about the caching-policies in a list format.

[-cache-setting <text>] - Cache Policy Name
   The input to this parameter is any one of the above listed caching-policies. If you use this parameter, the command displays information corresponding to the specified caching-policy.

[-class <QoS Configuration Class>] - Cache Policy Class
   The input to this parameter is one of the following: {undefined|preset|user-defined|system-defined|autovolume}. If you use this parameter, the command displays information corresponding to the specified policy-group class.

[-default {true|false}] - Is Default?
   The input to this parameter is true and false. If you use this parameter, the command displays information corresponding to entries that have the specified default value.

[-num-workloads <integer>] - Number Of Workloads With This Policy
   The input to this parameter is an integer. If you use this parameter, the command displays information about policy-groups matching the specified number of workloads.

qos statistics characteristics commands

Policy Group characterization

qos statistics characteristics show

Display QoS policy group characterization

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The qos statistics characteristics show command displays data that characterizes the behavior of QoS policy groups.

The command displays the following data:

• The QoS policy group name (Policy Group)
• Input/output operations performed per second (IOPS)
• Throughput achieved in kilobytes per second (KB/s) or megabytes per second (MB/s) as appropriate (Throughput)
• Request size in bytes (B) (Request size)
• Read percentage from total I/O (Read)
• Concurrency, which indicates the number of concurrent users generating the I/O traffic (Concurrency)

The results displayed per iteration are sorted by IOPS. Each iteration starts with a row that displays the total IOPS used across all QoS policy groups. Other columns in this row are either totals or averages.

Parameters

[-node {<nodename>|local}] - Node
Selects the policy groups that match this parameter value. If you do not specify this parameter, the command displays data for the entire cluster.

[-iterations <integer>] - Number of Iterations
Specifies the number of times the display is refreshed before terminating. If you do not specify this parameter, the command iterates until interrupted by Ctrl-C.

{ [ -rows <integer>] - Number of Rows in the Output
Specifies the number of busiest QoS policy groups to display. Valid values are from 1 to 20. The default value is 10.

[ -policy-group <text>] - QoS Policy Group Name
Selects the QoS policy group whose name matches the specified value. If you do not specify this parameter, the command displays data for all QoS policy groups.

[-refresh-display {true|false}] - Toggle Screen Refresh Between Each Iteration
Specifies the display style. If true, the command clears the display after each data iteration. If false, the command displays each data iteration below the previous one. The default is false.

Examples

```
cluster1::> qos statistics characteristics show -iterations 100 -rows 4
Policy Group     IOPS  Throughput Request size  Read  Concurrency
------------------------ --------------- ------------  ----  -----------
-total-             31  304.00KB/s    10041B    0%          16
_System-Best-Effort 15   0KB/s    0B    0%      0
vol1                11  44.00KB/s    4096B    0%         40
```

Commands: Manual Page Reference
The example above displays the characteristics of the 4 QoS policy groups with the highest IOPS values and refreshes the display 100 times before terminating.

### qos statistics latency commands

**Latency breakdown**

### qos statistics latency show

Display latency breakdown data per QoS policy group

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**

The `qos statistics latency show` command displays the average latencies for QoS policy groups across the various Data ONTAP subsystems.

The command displays the following data:

- The QoS policy group name (Policy Group)
- Total latency observed per I/O operation (Latency)
- Latency observed per I/O operation in the Network subsystem (Network)
- Latency observed per I/O operation across the internally connected nodes in a Cluster (Cluster)
- Latency observed per I/O operation in the Data management subsystem (Data)
- Latency observed per I/O operation in the Storage subsystem (Disk)
- Latency observed per I/O operation in the QoS subsystem (QoS)
- Latency observed per I/O operation for NVRAM transfer (NVRAM)
- Latency observed per I/O operation for Object Store(Cloud) operations

The results displayed per iteration are sorted by the Latency field. Each iteration starts with a row that displays the average latency, in microseconds (us) or milliseconds (ms), observed across all QoS policy groups.
Parameters

[-node {<nodename>|local}] - Node

Selects the policy groups that match this parameter value. If you do not specify this parameter, the command displays data for the entire cluster.

[-iterations <integer>] - Number of Iterations

Specifies the number of times the display is refreshed before terminating. If you do not specify this parameter, the command iterates until interrupted by Ctrl-C.

[-rows <integer>] - Number of Rows in the Output

Specifies the number of busiest QoS policy groups to display. Valid values are from 1 to 20. The default value is 10.

[-policy-group <text>] - QoS Policy Group Name

Selects the QoS policy group whose name matches the specified value. If you do not specify this parameter, the command displays data for all QoS policy groups.

[-refresh-display {true|false}] - Toggle Screen Refresh Between Each Iteration

Specifies the display style. If true, the command clears the display after each data iteration. If false, the command displays each data iteration below the previous one. The default is false.

Examples

```
cluster1::> qos statistics latency show -iterations 100 -rows 3

0ms

The example above displays latencies for the 3 QoS policy groups with the highest latencies and refreshes the display 100 times before terminating.
```

```
cluster1::> qos statistics latency show -iterations 100 -policy-group pg1

Policy Group     Latency    Network    Cluster       Data       Disk        QoS
NVRAM       Cloud
------------- ---------- ---------- ---------- ---------- ---------- ---------- -----------
-Total-        110.35ms   110.02ms        0ms   327.00us        0ms        0ms
0ms
```

The example above displays latencies for the 3 QoS policy groups with the highest latencies and refreshes the display 100 times before terminating.
qos statistics performance commands

System performance

qos statistics performance show

Display system performance data per QoS policy group

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The qos statistics performance show command shows the current system performance levels that QoS policy groups are achieving.

The command displays the following data:

- The QoS policy group name (Policy Group)
- Input/output operations performed per second (IOPS)
- Throughput in kilobytes per second (KB/s) or megabytes per second (MB/s) as appropriate (Throughput)
- Latency observed per request in microseconds (us) or milliseconds (ms) as appropriate (Latency)

The results displayed per iteration are sorted by IOPS. Each iteration starts with a row that displays the total IOPS used across all QoS policy groups. Other columns in this row are either totals or averages.

Parameters
- `-node {<nodename>|local}]` - Node
  Selects the policy groups that match this parameter value. If you do not specify this parameter, the command displays data for the entire cluster.

- `-iterations <integer>]` - Number of Iterations
  Specifies the number of times the display is refreshed before terminating. If you do not specify this parameter, the command iterates until interrupted by Ctrl-C.

- `{ [-rows <integer>]` - Number of Rows in the Output
  Specifies the number of busiest QoS policy groups to display. Valid values are from 1 to 20. The default value is 10.

- `[-policy-group <text>]` - QoS Policy Group Name
  Selects the QoS policy group whose name matches the specified value. If you do not specify this parameter, the command displays data for all QoS policy groups.
[-refresh-display {true|false}] - Toggle Screen Refresh Between Each Iteration

Specifies the display style. If true, the command clears the display after each data iteration. If false, the command displays each data iteration below the previous one. The default is false.

Examples

```
cluster1::> qos statistics performance show -iterations 100 -rows 4

<table>
<thead>
<tr>
<th>Policy Group</th>
<th>IOPS</th>
<th>Throughput</th>
<th>Latency</th>
</tr>
</thead>
<tbody>

qos statistics resource commands

Resource utilization

qos statistics resource cpu commands

CPU utilization

qos statistics resource cpu show

Display CPU resource utilization data per QoS policy group

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The qos statistics resource cpu show command displays the CPU utilization for QoS policy groups per node.

The command displays the following data:

- The QoS policy group name (Policy Group)
- CPU utilization observed in percentage (CPU)

The results displayed per iteration are sorted by total CPU utilization. Each iteration starts with a row that displays the total CPU utilization across all QoS policy groups.
Parameters
node {<nodename>|local} - Node
Selects the policy groups that match this parameter value.

-iterations <integer> - Number of Iterations
Specifies the number of times the display is refreshed before terminating. If you do not specify this parameter, the command iterates until interrupted by Ctrl-C.

-rows <integer> - Number of Rows in the Output
Specifies the number of busiest QoS policy groups to display. Valid values are from 1 to 20. The default value is 10.

-policy-group <text> - QoS Policy Group Name
Selects the QoS policy group whose name matches the specified value. If you do not specify this parameter, the command displays data for all QoS policy groups.

-refresh-display {true|false} - Toggle Screen Refresh Between Each Iteration
Specifies the display style. If true, the command clears the display after each data iteration. If false, the command displays each data iteration below the previous one. The default is false.

Examples

```
classcluster1::> qos statistics resource cpu show -node nodeA -iterations 100 -rows 3
<table>
<thead>
<tr>
<th>Policy Group</th>
<th>CPU</th>
</tr>
</thead>
<tbody>
<tr>
<td>-total- (100%)</td>
<td>9%</td>

qos statistics commands
**qos statistics resource disk commands**

**Disk utilization**

**qos statistics resource disk show**

Display disk resource utilization data per QoS policy group

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**

The *qos statistics resource disk show* command displays the disk utilization for QoS policy groups per node. The disk utilization shows the percentage of time spent on the disk during read and write operations. The command displays disk utilization for system-defined policy groups; however, their disk utilization is not included in the total utilization. The command only supports hard disks.

The command displays the following data:

- The QoS policy group name (Policy Group)
- Disk utilization (Disk)
- The number of HDD data disks utilized (Number of HDD Disks)

The results displayed are sorted by total disk utilization. Each iteration starts with a row that displays the total disk utilization across all QoS policy groups.

**Parameters**

- `-node <nodename> | local` - Node
  
  Selects the policy groups that match this parameter value.

- `[-iterations <integer> ]` - Number of Iterations
  
  Specifies the number of times the display is refreshed before terminating. If you do not specify this parameter, the command iterates until interrupted by Ctrl-C.

- `[-rows <integer> ]` - Number of Rows in the Output
  
  Specifies the number of busiest QoS policy groups to display. Valid values are from 1 to 20. The default value is 10.

- `[-policy-group <text> ]` - QoS Policy Group Name
  
  Selects the QoS policy group whose name matches the specified value. If you do not specify this parameter, the command displays data for all QoS policy groups.

- `[-refresh-display (true | false) ]` - Toggle Screen Refresh Between Each Iteration
  
  Specifies the display style. If true, the command clears the display after each data iteration. If false, the command displays each data iteration below the previous one. The default is false.

**Examples**

```
cluster1::> qos statistics resource disk show -node nodeA -iterations 100 -rows 3
Policy Group  Disk Number of HDD Disks
------------------------ -------- -------------------
-total-         40%          27
pg1             22%           5
```

**Commands:** Manual Page Reference
The example above displays the total disk utilization for the 3 QoS policy groups with the highest disk utilization and it refreshes the display 100 times before terminating.

```
cluster1::> qos statistics resource disk show -node local -iterations 100 -policy-group pg1
```

<table>
<thead>
<tr>

<td>24</td>
</tr>
</tbody>
</table>

**qos statistics volume commands**

The volume directory

**qos statistics volume characteristics commands**

The characteristics directory

**qos statistics volume characteristics show**

Display volume characteristics

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**

The qos statistics volume characteristics show command displays data that characterizes the behavior of volumes.

The command displays the following data:

- QoS volume name (Workload)
- QoS workload ID (ID)
- Input/output operations per second (IOPS)
- Throughput achieved in kilobytes per second (KB/s) or megabytes per second (MB/s) as appropriate (Throughput)
- Request size in bytes (B) (Request size)
- Read percentage from total IOPS (Read)
- Concurrency, which indicates the number of concurrent users generating the I/O traffic (Concurrency)

The results displayed per iteration are sorted by IOPS. Each iteration starts with a row that displays the total IOPS used across all volumes. Other columns in this row are either totals or averages.
Parameters

[-node {<nodename>|local}] - Node

Selects the volumes that match this parameter value. If you do not specify this parameter, the command displays data for the entire cluster.

{ [-rows <integer>] - Number of Rows in the Output

Specifies the number of busiest QoS policy groups to display. The default setting is 10. The allowed range of values is 1 to 20.

| -vserver <vserver name> - Vserver Name

Specifies the Vserver to which the volume belongs.

-volume <volume name> - Volume Name

Selects the characteristic data that match this parameter value. Enter a complete volume name or press the <Tab> key to complete the name. Wildcard query characters are not supported.

[-iterations <integer>] - Number of Iterations

Specifies the number of times the display is refreshed before terminating. If you do not specify this parameter, the command iterates until interrupted by Ctrl-C.

[-refresh-display {true|false}] - Toggle Screen Refresh Between Each Iteration

Specifies the display style. If true, the command clears the display after each data iteration. If false, the command displays each data iteration below the previous one. The default is false.

[-show-flexgroup-as-constituents {true|false}] - Display Flexgroups as Constituents

If the parameter is specified and if the value is true, it will display data for FlexVols and Flexgroup Constituents. Otherwise it will display data for FlexVols and Flexgroups.

Examples

```
cluster1::> qos statistics volume characteristics show -iterations 100 -rows 3
Workload ID IOPS Throughput Request size Read Concurrency
--------- ------ ---------------- ------------ ---- -----------
-total-- - 68 176.00KB/s 2650B 7% 8
vol_1-wid103 103 24 96.00KB/s 4096B 20% 13
vol_2-wid104 104 1 0KB/s 0B 0% 0
-total-- - 157 528.00KB/s 3443B 3% 4
vol_1-wid103 103 43 172.00KB/s 4096B 0% 0
vol_2-wid104 104 48 192.00KB/s 4096B 0% 9
vol_1-wid103 103 41 164.00KB/s 4096B 14% 6
-total-- - 274 1016.00KB/s 3797B 2% 2
vol_1-wid103 103 85 340.00KB/s 4096B 8% 4
vol_2-wid104 104 85 340.00KB/s 4096B 0% 1
vol_1-wid103 103 84 336.00KB/s 4096B 0% 3
```

The example above displays characteristics for the 3 volumes with the highest IOPS and it refreshes the display 100 times before terminating.

```
cluster1::> qos statistics volume characteristics show -vserver vs0 -volume vs0_vol0 -iterations 100
Workload ID IOPS Throughput Request Size Read Concurrency
--------- ------ ---------------- ------------ ---- -----------
-total-- - 1567 783.33KB/s 512Kb 90% 2
vs0_vol0-wid1... 15658 785 392.33KB/s 512Kb 89% 1
-total-- - 1521 760.50KB/s 512Kb 90% 1
vs0_vol0-wid1... 15658 982 491.17KB/s 512Kb 90% 0
-total-- - 1482 741.00KB/s 512Kb 89% 0
vs0_vol0-wid1... 15658 945 472.50KB/s 512Kb 90% 0
```

Commands: Manual Page Reference
qos statistics volume latency commands

The latency directory

qos statistics volume latency show

Display latency breakdown data per volume

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The qos statistics volume latency show command displays the average latencies for volumes on Data ONTAP subsystems.

The command displays the following data:
- The QoS volume name (Workload)
- The QoS workload ID (ID)
- Total latency observed per I/O operation (Latency)
- Latency observed per I/O operation in the Network subsystem (Network)
- Latency observed per I/O operation across the internally connected nodes in a Cluster (Cluster)
- Latency observed per I/O operation in the Data management subsystem (Data)
- Latency observed per I/O operation in the Storage subsystem (Disk)
- Latency observed per I/O operation in the QoS subsystem (QoS)
- Latency observed per I/O operation for NVRAM transfer (NVRAM)
- Latency observed per I/O operation for Object Store(Cloud) operations

The results displayed per iteration are sorted by the total latency field. Each iteration starts with a row that displays the average latency, in microseconds (us) or milliseconds (ms) observed across all volumes.

Parameters

[-node {<nodename>|local}] - Node
Selects the volumes that match this parameter value. If you do not specify this parameter, the command displays data for the entire cluster.

{ [-rows <integer>] - Number of Rows in the Output
Specifies the number of busiest QoS policy groups to display. The default setting is 10. The allowed range of values is 1 to 20.

| -vserver <vserver name> - Vserver Name
Specifies the Vserver to which the volume belongs.

-volume <volume name}] - Volume Name
Selects the latency data that match this parameter value. Enter a complete volume name or press the <Tab> key to complete the name. Wildcard query characters are not supported.
[-iterations <integer>] - Number of Iterations
Specifications the number of times that the command refreshes the display with updated data before terminating. If you do not specify this parameter, the command iterates until interrupted by Ctrl-C.

[-refresh-display (true|false)] - Toggle Screen Refresh Between Each Iteration
Specifications the display style. If true, the command clears the display after each data iteration. If false, the command displays each data iteration below the previous one. The default is false.

[-show-flexgroup-as-constituents (true|false)] - Display Flexgroups as Constituents
If the parameter is specified and if the value is true, it will display data for FlexVols and Flexgroup Constituents. Otherwise it will display data for FlexVols and Flexgroups.

Examples

```
cluster1::> qos statistics volume latency show -iterations 100 -rows 3
Workload        ID  Latency    Network  Cluster       Data     Disk      QoS      NVRAM

Commands: Manual Page Reference
qos statistics volume performance commands

The performance directory

qos statistics volume performance show

Display system performance data per volume

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The qos statistics volume performance show command shows the current system performance that each volume is achieving.

The command displays the following data:

- The QoS volume name (Workload)
- The QoS workload ID (ID)
- Input/output operations performed per second (IOPS)
- Throughput in kilobytes per second (KB/s) or megabytes per second (MB/s) as appropriate (Throughput)
- Latency observed per request in microseconds (us) or milliseconds (ms) as appropriate (Latency)

The results displayed per iteration are sorted by IOPS. Each iteration starts with a row that displays the total IOPS used across all volumes. Other columns in this row are either totals or averages.

Parameters

- `-node {<nodename>|local}]` - Node
  Selects the volumes that match this parameter value. If you do not specify this parameter, the command displays data for the entire cluster.

- `{ [-rows <integer>] }` - Number of Rows in the Output
  Specifies the number of busiest QoS policy groups to display. The default setting is 10. The allowed range of values is 1 to 20.

- `|-vserver <vserver name>` - Vserver Name
  Specifies the Vserver to which the volume belongs.

- `-volume <volume name>` - Volume Name
  Selects the performance data that match this parameter value. Enter a complete volume name or press the <Tab> key to complete the name. Wildcard query characters are not supported.

- `|-iterations <integer>]` - Number of Iterations
  Specifies the number of times the display is refreshed before terminating. If you do not specify this parameter, the command iterates until interrupted by Ctrl-C.

- `|-refresh-display (true|false)]` - Toggle Screen Refresh Between Each Iteration
  Specifies the display style. If true, the command clears the display after each data iteration. If false, the command displays each data iteration below the previous one. The default is false.
-show-flexgroup-as-constituents {true|false} - Display Flexgroups as Constituents

If the parameter is specified and if the value is true, it will display data for FlexVols and Flexgroup Constituents. Otherwise it will display data for FlexVols and Flexgroups.

**Examples**

```
cluster1::> qos statistics volume performance show -iterations 100 -rows 3
Workload          ID     IOPS       Throughput    Latency
--------------- ------ -------- ---------------- ----------
-total-            -     -         -                -          -
vol_2-wid104      104     28       1.75MB/s      412.78ms

**qos statistics volume resource commands**

The resource directory

**qos statistics volume resource cpu commands**

The cpu directory

**qos statistics volume resource cpu show**

Display CPU resource utilization data per volume

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**

The qos statistics volume resource cpu show command displays the CPU utilization for volumes per node.

The command displays the following data:

- The QoS volume name (Workload)
• The QoS workload ID (ID)
• CPU utilization observed in percentage (CPU)

The results displayed per iteration are sorted by total CPU utilization. Each iteration starts with a row that displays the total CPU utilization across all volumes.

Parameters
- **node {<nodename>|local} - Node**
  Selects the volumes that match this parameter value.

  { [-rows <integer>] - Number of Rows in the Output
  Specifies the number of busiest QoS policy groups to display. The default setting is 10. The allowed range of values is 1 to 20.

  | -vserver <vserver name> - Vserver Name
  Specifies the Vserver to which the volume belongs.

  -volume <volume name> - Volume Name
  Selects the CPU utilization data that match this parameter value. Enter a complete volume name or press the <Tab> key to complete the name. Wildcard query characters are not supported.

  [ -iterations <integer>] - Number of Iterations
  Specifies the number of times the display is refreshed before terminating. If you do not specify this parameter, the command iterates until interrupted by Ctrl-C.

  [ -refresh-display {true|false}] - Toggle Screen Refresh Between Each Iteration
  Specifies the display style. If true, the command clears the display after each data iteration. If false, the command displays each data iteration below the previous one. The default is false.

  [ -show-flexgroup-as-constituents {true|false}] - Display Flexgroups as Constituents
  If the parameter is specified and if the value is true, it will display data for FlexVols and Flexgroup Constituents. Otherwise it will display data for FlexVols and Flexgroups.

Examples

```
cluster1::> qos statistics volume resource cpu show -node nodeA -iterations 100 -rows 3
Workload        ID   CPU
--------------- ----- ----- 
--total- (100%)  -    9%
vs0vol1-wid-102  102    5%
vs0vol2-wid-121  121    2%
vs2_vol0-wid-..  212    2%
--total- (100%)  -    6%
vs0vol1-wid-102  102    5%
vs0vol2-wid-121  121    3%
vs2_vol0-wid-..  212    2%
```

The example above displays total CPU utilization for the 3 volumes with the highest CPU utilization and it refreshes the display 100 times before terminating.

```
cluster1::> qos statistics volume resource cpu show -node local -vserver vs0 -volume vs0_vol1 -iterations 100
Workload        ID   CPU
--------------- ----- ----- 
--total- (100%)  -    2%
vs0_vol1-wid7..  7916    2%
--total- (100%)  -    2%
vs0_vol1-wid7..  7916    2%
--total- (100%)  -    2%
vs0_vol1-wid7..  7916    2%
```

### qos statistics volume resource disk commands

The disk directory

**qos statistics volume resource disk show**

Display disk resource utilization data per volume

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**

The `qos statistics volume resource disk show` command displays the disk utilization for volumes per node. The disk utilization shows the percentage of time spent on the disk during read and write operations. The command only supports hard disks.

The command displays the following data:

- The QoS volume name (Workload)
- The QoS workload ID (ID)
- Disk utilization (Disk)
- The number of HDD data disks utilized (Number of HDD Disks)

The results displayed are sorted by total disk utilization. Each iteration starts with a row that displays the total disk utilization across all volumes.

**Parameters**

- `-node {<nodename>|local} - Node`
  
  Selects the volumes that match this parameter value.

- `[-rows <integer>] - Number of Rows in the Output`
  
  Specifies the number of busiest QoS policy groups to display. The default setting is 10. The allowed range of values is 1 to 20.

- `| <vserver <vserver name> - Vserver Name`
  
  Specifies the Vserver to which the volume belongs.
-volume <volume name> - Volume Name
Selects the disk utilization data that match this parameter value. Enter a complete volume name or press the
<Tab> key to complete the name. Wildcard query characters are not supported.

-[iterations <integer>] - Number of Iterations
Specifies the number of times the display is refreshed before terminating. If you do not specify this parameter,
the command iterates until interrupted by Ctrl-C.

-[refresh-display (true|false)] - Toggle Screen Refresh Between Each Iteration
Specifies the display style. If true, the command clears the display after each data iteration. If false, the
command displays each data iteration below the previous one. The default is false.

-[show-flexgroup-as-constituents (true|false)] - Display Flexgroups as Constituents
If the parameter is specified and if the value is true, it will display data for FlexVols and Flexgroup
Constituents. Otherwise it will display data for FlexVols and Flexgroups.

**Examples**

cluster1::> qos statistics volume resource disk show -node nodeB -iterations 100 -rows

<table>

**qos statistics workload commands**
Detail by workload

**qos statistics workload characteristics commands**
Workload characterization
qos statistics workload characteristics show

Display QoS workload characterization

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The qos statistics workload characteristics show command displays data that characterizes the behavior of QoS workloads.

The command displays the following data:

- The QoS workload name (Workload)
- The QoS workload ID (ID)
- Input/output operations performed per second (IOPS)
- Throughput achieved in kilobytes per second (KB/s) or megabytes per second (MB/s) as appropriate (Throughput)
- Request size in bytes (B) (Request size)
- Read percentage from total IOPS (Read)
- Concurrency, which indicates the number of concurrent users generating the I/O traffic (Concurrency)

The results displayed per iteration are sorted by IOPS. Each iteration starts with a row that displays the total IOPS used across all QoS workloads. Other columns in this row are either totals or averages.

Parameters

[-node {<nodename> | local}] - Node

Selects the QOS workloads that match this parameter value. If you do not specify this parameter, the command displays data for the entire cluster.

[-iterations <integer>] - Number of Iterations

Specifies the number of times the display is refreshed before terminating. If you do not specify this parameter, the command iterates until interrupted by Ctrl-C.

[-refresh-display {true | false}] - Toggle Screen Refresh Between Each Iteration

Specifies the display style. If true, the command clears the display after each data iteration. If false, the command displays each data iteration below the previous one. The default is false.

{ [-rows <integer>] - Number of Rows in the Output

Specify the number of busiest QoS policy groups to display. Valid values are from 1 to 20. The default value is 10.

[-policy-group <text>] - QoS Policy Group Name

Selects the QoS workloads that belong to the QoS policy group specified by this parameter value. If you do not specify this parameter, the command displays data for all QoS workloads.

[-workload <text>] - QoS Workload Name

Selects the QoS workload that match this parameter value. If you do not specify this parameter, the command displays data for all QoS workloads.

[-workload-id <integer>] - QoS Workload ID

Selects the QoS workload that match the QoS workload ID specified by this parameter value.

[-show-flexgroup-as-constituents {true | false}] - Display Flexgroups as Constituents

If the parameter is specified and if the value is true, it will display data for FlexVols and Flexgroup Constituents. Otherwise it will display data for FlexVols and Flexgroups.
Examples

```
cluster1::> qos statistics workload characteristics show -iterations 100 -rows 4

qos statistics workload latency commands

Latency breakdown

qos statistics workload latency show

Display latency breakdown data per QoS workload

Availability: This command is available to cluster administrators at the admin privilege level.
Description
The qos statistics workload latency show command displays the average latencies for QoS workloads on Data ONTAP subsystems.

The command displays the following data:

- The QoS workload name (Workload)
- The QoS workload ID (ID)
- Total latency observed per I/O operation (Latency)
- Latency observed per I/O operation in the Network subsystem (Network)
- Latency observed per I/O operation across the internally connected nodes in a Cluster (Cluster)
- Latency observed per I/O operation in the Data management subsystem (Data)
- Latency observed per I/O operation in the Storage subsystem (Disk)
- Latency observed per I/O operation in the QoS subsystem (QoS)
- Latency observed per I/O operation for NVRAM transfer (NVRAM)
- Latency observed per I/O operation for Object Store(Cloud) operations

The results displayed per iteration are sorted by the total latency field. Each iteration starts with a row that displays the average latency, in microseconds (us) or milliseconds (ms) observed across all QoS workloads.

Parameters

[-node {<nodename>|local}] - Node
Selects the QoS workloads that match this parameter value. If you do not specify this parameter, the command displays data for the entire cluster.

[-iterations <integer>] - Number of Iterations
Specifies the number of times that the command refreshes the display with updated data before terminating. If you do not specify this parameter, the command continues to run until you interrupt it by pressing Ctrl-C.

[-refresh-display {true|false}] - Toggle Screen Refresh Between Each Iteration
Specifies the display style. If true, the command clears the display after each data iteration. If false, the command displays each data iteration below the previous one. The default is false.

{ [-rows <integer>] - Number of Rows in the Output
Specifies the number of busiest QoS policy groups to display. Valid values are from 1 to 20. The default value is 10.

[-policy-group <text>] - QoS Policy Group Name
Selects the QoS workloads that belong to the QoS policy group specified by this parameter value. If you do not specify this parameter, the command displays data for all QoS workloads.

[-workload <text>] - QoS Workload Name
Selects the QoS workload that match this parameter value. If you do not specify this parameter, the command displays data for all QoS workloads.

[-workload-id <integer>] - QoS Workload ID
Selects the QoS workload that match the QoS workload ID specified by this parameter value.

[-show-flexgroup-as-constituents {true|false}] - Display Flexgroups as Constituents
If the parameter is specified and if the value is true, it will display data for FlexVols and Flexgroup Constituents. Otherwise it will display data for FlexVols and Flexgroups.

qos statistics workload performance commands

System performance

qos statistics workload performance show

Display system performance data per QoS workload

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The qos statistics workload performance show command shows the current system performance that each QoS workload is achieving.

The command displays the following data:

- The QoS workload name (Workload)
- The QoS workload ID (ID)
- Input/output operations performed per second (IOPS)
- Throughput in kilobytes per second (KB/s) or megabytes per second (MB/s) as appropriate (Throughput)
- Latency observed per request in microseconds (us) or milliseconds (ms) as appropriate (Latency)

The results displayed per iteration are sorted by IOPS. Each iteration starts with a row that displays the total IOPS used across all QoS workloads. Other columns in this row are either totals or averages.

Parameters
[-node {<nodename>|local}] - Node
Selects the QoS workloads that match this parameter value. If you do not specify this parameter, the command displays data for the entire cluster.

[-iterations <integer>] - Number of Iterations
Specifies the number of times the display is refreshed before terminating. If you do not specify this parameter, the command iterates until interrupted by Ctrl-C.

[-refresh-display {true|false}] - Toggle Screen Refresh Between Each Iteration
Specifies the display style. If true, the command clears the display after each data iteration. If false, the command displays each data iteration below the previous one. The default is false.

{ [-rows <integer>] - Number of Rows in the Output
Specifies the number of busiest QoS policy groups to display. Valid values are from 1 to 20. The default value is 10.}
[-policy-group <text>] - QoS Policy Group Name

Selects the QoS workloads that belong to the QoS policy group specified by this parameter value. If you do not specify this parameter, the command displays data for all QoS workloads.

[-workload <text>] - QoS Workload Name

Selects the QoS workload that match this parameter value. If you do not specify this parameter, the command displays data for all QoS workloads.

[-workload-id <integer>] - QoS Workload ID

Selects the QoS workload that match the QoS workload ID specified by this parameter value.

[-show-flexgroup-as-constituents {true|false}] - Display Flexgroups as Constituents

If the parameter is specified and if the value is true, it will display data for FlexVols and Flexgroup Constituents. Otherwise it will display data for FlexVols and Flexgroups.

**Examples**

```
cluster1::> qos statistics workload performance show -iterations 100 -rows 4
<table>
<thead>
<tr>

```

The example above displays the system performance for the 2 QoS workloads belonging to QoS policy group pg1 with the highest IOPS and it refreshes the display 100 times before terminating.
qos statistics workload resource commands

Resource utilization

qos statistics workload resource cpu commands

CPU utilization

qos statistics workload resource cpu show

Display CPU resource utilization data per QoS workload

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The qos statistics workload resource cpu show command displays the CPU utilization for QoS workloads per node. The command displays the following data:

- The QoS workload name (Workload)
- The QoS workload ID (ID)
- CPU utilization observed in percentage (CPU)

The results displayed per iteration are sorted by total CPU utilization. Each iteration starts with a row that displays the total CPU utilization across all QoS workloads.

Parameters

- node {<nodename>|local} - Node
  Selects the QOS workloads that match this parameter value.

  [-iterations <integer>] - Number of Iterations
  Specifies the number of times the display is refreshed before terminating. If you do not specify this parameter, the command iterates until interrupted by Ctrl-C.

  [-refresh-display {true|false}] - Toggle Screen Refresh Between Each Iteration
  Specifies the display style. If true, the command clears the display after each data iteration. If false, the command displays each data iteration below the previous one. The default is false.

  { [-rows <integer>] - Number of Rows in the Output
    Specifies the number of busiest QoS policy groups to display. Valid values are from 1 to 20. The default value is 10.

  [-policy-group <text>] - QoS Policy Group Name
    Selects the QoS workloads that belong to the QoS policy group specified by this parameter value. If you do not specify this parameter, the command displays data for all QoS workloads.

  [-workload <text>] - QoS Workload Name
    Selects the QoS workload that match this parameter value. If you do not specify this parameter, the command displays data for all QoS workloads.

  [-workload-id <integer>] - QoS Workload ID
    Selects the QoS workload that match the QoS workload ID specified by this parameter value.
-show-flexgroup-as-constituents {true|false} - Display Flexgroups as Constituents

If the parameter is specified and if the value is true, it will display data for FlexVols and Flexgroup Constituents. Otherwise it will display data for FlexVols and Flexgroups.

Examples

```bash
cluster1::> qos statistics workload resource cpu show -node nodeA -iterations 100 -rows 3

<table>
<thead>
<tr>
<th>Workload</th>
<th>ID</th>
<th>CPU</th>
</tr>
</thead>
<tbody>
<tr>
<td>-total- (100%)</td>
<td>-</td>
<td>9%</td>
</tr>
<tr>
<td>vs0-wid-102</td>
<td>102</td>
<td>5%</td>
</tr>
<tr>
<td>file-bigvmdk-..</td>
<td>121</td>
<td>2%</td>
</tr>
<tr>
<td>vs2_vol0-wid-..</td>
<td>212</td>

```

qos statistics commands
qos statistics workload resource disk commands

Disk utilization

qos statistics workload resource disk show

Display disk resource utilization data per QoS workload

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The qos statistics workload resource disk show command displays the disk utilization for QoS workloads per node. The disk utilization shows the percentage of time spent on the disk during read and write operations. The command displays disk utilization for system-defined workloads; however, their disk utilization is not included in the total utilization. The command only supports hard disks.

The command displays the following data:

- The QoS workload name (Workload)
- The QoS workload ID (ID)
- Disk utilization (Disk)
- The number of HDD data disks utilized (Number of HDD Disks)

The results displayed are sorted by total disk utilization. Each iteration starts with a row that displays the total disk utilization across all QoS workloads.

Parameters

- `-node <nodename>|local` - Node
  
  Selects the QOS workloads that match this parameter value.

- `[ -iterations <integer> ]` - Number of Iterations
  
  Specifies the number of times the display is refreshed before terminating. If you do not specify this parameter, the command iterates until interrupted by Ctrl-C.

- `[ -refresh-display {true|false} ]` - Toggle Screen Refresh Between Each Iteration
  
  Specifies the display style. If true, the command clears the display after each data iteration. If false, the command displays each data iteration below the previous one. The default is false.

- `[ [-rows <integer>] ]` - Number of Rows in the Output
  
  Specifies the number of busiest QoS policy groups to display. Valid values are from 1 to 20. The default value is 10.

- `[ -policy-group <text> ]` - QoS Policy Group Name
  
  Selects the QoS workloads that belong to the QoS policy group specified by this parameter value. If you do not specify this parameter, the command displays data for all QoS workloads.

- `[ [-workload <text>] ]` - QoS Workload Name
  
  Selects the QoS workload that match this parameter value. If you do not specify this parameter, the command displays data for all QoS workloads.
[-workload-id <integer>] - QoS Workload ID
Selects the QoS workload that match the QoS workload ID specified by this parameter value.

[-show-flexgroup-as-constituents {true|false}] - Display Flexgroups as Constituents
If the parameter is specified and if the value is true, it will display data for FlexVols and Flexgroup Constituents. Otherwise it will display data for FlexVols and Flexgroups.

Examples

cluster1::> qos statistics workload resource disk show -node nodeB -iterations 100 -rows 3
<table>
<thead>
<tr>

**qos workload commands**

QoS workload settings

**qos workload show**

Display a list of workloads

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**

Shows the current status of workloads on a cluster. Use this command to determine the types of workloads that are currently on a cluster. The types of workloads include: system-defined, preset, and user-defined. The system generates system-defined and preset workloads. You cannot create, modify, or delete these workloads. Also, you can only modify or delete a user-defined workload, but cannot create one.

**Parameters**

{ [-fields <fieldname>, ... ]

If you specify the *-fields* *<fieldname>, ...* parameter, the command output also includes the specified field or fields. You can use *'-fields ?'* to display the fields to specify.

| [-instance ]] 

If you specify the *-instance* parameter, the command displays detailed information about all fields.

|--workload <text> | - Workload Name

If you use this parameter, the command displays the workloads that contain the specified workload name.

|--uuid <UUID> | - Workload UUID (privilege: advanced)

If you use this parameter, the command displays the workloads that contain the specified UUID.

|--class <QoS Configuration Class> | - Workload Class

If you use this parameter, the command displays the workloads that contain the specified class. The Class options include system-defined, preset, and user-defined.

|--wid <integer> | - Workload ID

If you use this parameter, the command displays the workloads that contain the specified internal workload ID.

|--category <text> | - Workload Category

If you use this parameter, the command displays the workloads that contain the specified category. The category options include Scanner and Efficiency.

|--policy-group <text> | - Policy Group Name

If you use this parameter, the command displays the workloads that match the specified policy group name.

|--read-ahead <text> | - Read-ahead Tunables

If you use this parameter, the command displays the workloads that contain the specified read-ahead cache tunable.

|--vserver <vserver name> | - Vserver

If you use this parameter, the command displays the workloads that match the specified Vserver.

|--volume <volume name> | - Volume

If you use this parameter, the command displays the workloads that match the specified volume.

|--qtree <qtree name> | - Qtree Name

If you use this parameter, the command displays the workloads that match the specified Qtree name.
[-lun <text>] - LUN Name
If you use this parameter, the command displays the workloads that match the specified LUN name.

[-file <text>] - File Path
If you use this parameter, the command displays the workloads that match the specified file path.

[-max-throughput <qos_tput>] - Maximum Throughput
Selects the workloads that match this parameter value
A maximum throughput limit specifies the throughput in IOPS that the workload must not exceed.

[-min-throughput <qos_tput>] - Minimum Throughput
Selects the workloads that match this parameter value
A minimum throughput specifies the desired performance level for a workload in IOPS.

[-is-adaptive {true|false}] - Adaptive
If you use this parameter, the command displays only adaptive workloads.

[-is-constituent {true|false}] - Is Constituent Volume
If this parameter is specified, the command displays information only about storage objects that either are or are not constituents of a FlexGroup, depending on the value provided.

Examples

cluster1::> qos workload show -class user-defined
<table>
<thead>
<tr>
<th>Workload</th>
<th>Wid</th>
<th>Policy Group</th>
<th>Vserver</th>
<th>Volume</th>
<th>LUN</th>
<th>Qtree</th>
<th>File Path</th>
</tr>
</thead>

<td>100</td>
<td>pg1</td>
<td>vs2</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
</tr>
</tbody>
</table>

Security Commands

The security directory

The security commands enable you to manage security for the management interface.

security snmpusers

Show SNMP users

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The security snmpusers displays the following information about SNMP users:

- User name
- Authentication method
- Hexadecimal engine ID
- Authentication protocol
- Privacy protocol
- Security group
Parameters

[-fields <fieldname>, ...]
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use ‘-fields ?’ to display the fields to specify.

[-instance]]
If you specify the -instance parameter, the command displays detailed information about all fields.

[-vserver <Vserver Name>] - Vserver
If this parameter is specified, the command displays information only about the SNMP user or users that belong to the specified Vserver.

[-username <text>] - User Name
If this parameter is specified, the command displays information only about the SNMP user with the specified user name.

[-authmethod <text>] - Authentication Method
If this parameter is specified, the command displays information only about the SNMP user or users that use the specified authentication method. Possible values include the following:

• community-SNMP community strings
• usm-SNMP user security model

[-remote-switch-ipaddress <IP Address>] - Remote Switch IP Address
If this parameter is specified, the command displays information only about the remote SNMP user or users that belong to the specified remote switch.

[-engineid <Hex String>] - Engine Id
If this parameter is specified, the command displays information only about the SNMP user or users that use the specified engine ID, specified in hexadecimal format.

[-authprotocol <text>] - Authentication Protocol
If this parameter is specified, the command displays information only about the SNMP user or users that use the specified authentication protocol.

[-privprotocol <text>] - Privacy Protocol
If this parameter is specified, the command displays information only about the SNMP user or users that use the specified privacy protocol.

[-securitygroup <text>] - Security Group
If this parameter is specified, the command displays information only about the SNMP user or users that belong to the specified security group.

Examples
The following example displays information about all SNMP users:

```
cluster1::> security snmpusers
 Protocols Security Remote
 Vserver Username AuthMethod EngineId Auth Priv Group Switch IP
-------- ------ ---------- ---------------- ---- ---- ---------  -----------
cluster1 comm1 community 8000031504312d38302d313233343536 - - readwrite
cluster1 private community 8000031504312d38302d313233343536 - - readwrite
cluster1 snmpuser1 usm 80000634b21000000533296869 - - readwrite 172.2.20.91
```
security audit commands
Manage administrative audit logging settings

security audit modify
Set administrative audit logging settings

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The `security audit modify` command modifies the following audit-logging settings for the management interface:

- Whether get requests for the CLI are audited
- Whether get requests for the Data ONTAP API (ONTAPI) are audited

Parameters

```
[-cliget [on|off]] - Enable Auditing of CLI Get Operations
```

This specifies whether get requests for the CLI are audited. The default setting is *off*.

```
[-httpget [on|off]] - Enable Auditing of HTTP Get Operations
```

This specifies whether get requests for the web (HTTP) interface are audited. The default setting is *off*.

```
[-ontapiget [on|off]] - Enable Auditing of Data ONTAP API Get Operations
```

This specifies whether get requests for the Data ONTAP API (ONTAPI) interface are audited. The default setting is *off*.

Examples
The following example turns off auditing of get requests for the CLI interface:

```
cluster1::> security audit modify -cliget off
```

security audit show
Show administrative audit logging settings

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The `security audit show` command displays the following audit-logging settings for the management interface:

- Whether get requests for the CLI are audited
- Whether get requests for the web (HTTP) interface are audited
- Whether get requests for the Data ONTAP API (ONTAPI) are audited

Audit log entries are written to the 'audit' log, viewable via the 'security audit log show' command.
Examples
The following example displays the audit-logging settings for the management interface:

```
cluster1::> security audit show
Auditing State for
Operation Get Requests
--------- ------------------
CLI off
HTTP off
ONTAPI off
```

security audit log commands
Display administrative audit logging entries

security audit log show
Display audit entries merged from multiple nodes in the cluster
Availability: This command is available to cluster administrators at the admin privilege level.

Description
The security audit log show command displays cluster-wide audit log messages. Messages from each node are interleaved in chronological order.

Parameters

```
{-fields <fieldname>, ...}
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

| {-detail }
This display option shows the individual fields of the audit record.

| {-instance }
If you specify the -instance parameter, the command displays detailed information about all fields.

{-timestamp <Date>} - Log Entry Timestamp
Selects the entries that match the specified input for timestamp. This will be in a human-readable format <day> <month> <day of month> <hour>:<min>:<sec> <year> in the local timezone.

{-node (<nodename>|local)} - Node
Selects the entries that match the specified input for node.

{-entry <text>} - Log Message Entry
Selects the entries that match the specified input for entry.

{-session-id <text>} - Session ID
This is the “session id” for this audit record. Each ssh/console session is assigned a unique session ID. Each ZAPI/HTTP/SNMP request is assigned a unique session ID.

{-command-id <text>} - Command ID
This is useful with ssh/console sessions. Each command in a session is assigned a unique command ID. Each ZAPI/HTTP/SNMP request does not have a command ID.

{-application <text>} - Protocol
This the application the used
[-location <text>] - Remote user location
   The remote IP address or remote access point.

[-vserver <text>] - Vserver name
   Storage Virtual Machine name

[-username <text>] - Username
   Username

[-input <text>] - Command being executed
   The operation being attempted

[-state {Pending|Success|Error}] - State of this audit request
   State of this request

[-message <text>] - Additional information and/or error message
   Additional information which may be error or informative message.

Show Commands

Manage Digital Certificates
Field description for all the certificate show commands.

security certificate create

Create and Install a Self-Signed Digital Certificate

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The security certificate create command creates and installs a self-signed digital certificate, which can be used for server authentication, for signing other certificates by acting as a certificate authority (CA), or for Data ONTAP as an SSL client. The certificate function is selected by the -type field. Self-signed digital certificates are not as secure as certificates signed by a CA. Therefore, they are not recommended in a production environment.

Parameters

-vserver <Vserver Name> - Name of Vserver
   This specifies the name of the Vserver on which the certificate will exist.

-common-name <FQDN or Custom Common Name> - FQDN or Custom Common Name
   This specifies the desired certificate name as a fully qualified domain name (FQDN) or custom common name or the name of a person. The supported characters, which are a subset of the ASCII character set, are as follows:
   • Letters a through z, A through Z
   • Numbers 0 through 9
   • Asterisk (*), period (.), underscore (_) and hyphen (-)
   The common name must not start or end with a "-" or a ".". The maximum length is 253 characters.

-type <type of certificate> - Type of Certificate
   This specifies the certificate type. Valid values are the following:
   • server - creates and installs a self-signed digital certificate and intermediate certificates to be used for server authentication
• **root-ca** - creates and installs a self-signed digital certificate to sign other certificates by acting as a certificate authority (CA)

• **client** - includes a self-signed digital certificate and private key to be used for Data ONTAP as an SSL client

`[-subtype <kmip-cert>]` - (DEPRECATED)-Certificate Subtype

**Note:** This parameter has been deprecated in ONTAP 9.6 and may be removed in a future release of Data ONTAP.

This specifies a certificate subtype. This optional parameter can have an empty value (the default). The only valid value is as follows:

• **kmip-cert** - this is a Key Management Interoperability Protocol (KMIP) certificate

`[-cert-name <text>]` - Unique Certificate Name

This specifies the system's internal identifier for the certificate. It must be unique within a Vserver. If not provided, it is automatically generated by the system.

`[-size <size of requested certificate in bits>]` - Size of Requested Certificate in Bits

This specifies the number of bits in the private key. The larger the value, the more secure is the key. The default is 2048. Possible values include 512, 1024, 1536, 2048 and 3072 when the "FIPS Mode" in "security config" is false. When the "FIPS Mode" is true, the possible values are 2048 and 3072.

`[-country <text>]` - Country Name

This specifies the country where the Vserver resides. The country name is a two-letter code. The default is US. Here is the list of country codes: Country Codes

`[-state <text>]` - State or Province Name

This specifies the state or province where the Vserver resides.

`[-locality <text>]` - Locality Name

This specifies the locality where the Vserver resides. For example, the name of a city.

`[-organization <text>]` - Organization Name

This specifies the organization where the Vserver resides. For example, the name of a company.

`[-unit <text>]` - Organization Unit

This specifies the unit where the Vserver resides. For example, the name of a section or a department within a company.

`[-email-addr <mail address>]` - Contact Administrator's Email Address

This specifies the email address of the contact administrator for the Vserver.

`[-expire-days <integer>]` - Number of Days until Expiration

This specifies the number of days until the certificate expires. The default value is 365 days. Possible values are between 1 and 3652.

`[-protocol <protocol>]` - Protocol

This specifies the protocol type. This parameter currently supports only the SSL protocol type. The default is SSL.

`[-hash-function <hashing function>]` - Hashing Function

This specifies the cryptographic hashing function for signing the certificate. The default is SHA256. Possible values include SHA1, SHA256, MD5, SHA224, SHA384 and SHA512 when the "FIPS Mode" in "security config" is false. When the "FIPS Mode" is true, the possible values are SHA224, SHA256, SHA384 and SHA512.
Examples

This example creates a server type, self-signed digital certificate for a Vserver named vs0 at a company whose custom common name is www.example.com and whose Vserver name is vs0.

```
cluster1::> security certificate create -vserver vs0 -common-name www.example.com -type server
```

This example creates a root-ca type, self-signed digital certificate with a 2048-bit private key generated by the SHA256 hashing function that will expire in 365 days for a Vserver named vs0 for use by the Software group in IT at a company whose custom common name is www.example.com, located in Sunnyvale, California, USA. The email address of the contact administrator who manages the Vserver is web@example.com.

```
cluster1::> security certificate create -vserver vs0 -common-name www.example.com -type root-ca -size 2048 -country US -state California -locality Sunnyvale -organization IT -unit Software -email-addr web@example.com -expire-days 365 -hash-function SHA256
```

This example creates a client type of self-signed digital certificate for a Vserver named vs0 at a company that uses Data ONTAP as an SSL client. The company's custom common name is www.example.com and its Vserver name is vs0.

```
cluster1::> security certificate create -vserver vs0 -common-name www.example.com -type client -size 2048 -country US -state California -locality Sunnyvale -organization IT -unit Software -email-addr web@example.com -expire-days 365 -hash-function SHA256
```

security certificate delete

Delete an Installed Digital Certificate

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description

This command deletes an installed digital security certificate.

Parameters

- `vserver <Vserver Name>` - Name of Vserver
  
  This specifies the Vserver that contains the certificate.

- `common-name <FQDN or Custom Common Name>` - FQDN or Custom Common Name
  
  This specifies the desired certificate name as a fully qualified domain name (FQDN) or custom common name or the name of a person. The supported characters, which are a subset of the ASCII character set, are as follows:
  
  • Letters a through z, A through Z
  
  • Numbers 0 through 9
  
  • Asterisk (*), period (.), underscore (_) and hyphen (-)
  
  The common name must not start or end with a "-" or a ".". The maximum length is 253 characters.

- `serial <text>` - Serial Number of Certificate
  
  This specifies the certificate serial number.

- `ca <text>` - Certificate Authority
  
  This specifies the certificate authority (CA).

- `type <type of certificate>` - Type of Certificate
  
  This specifies the certificate type. Valid values are the following:
• server - includes server certificates and intermediate certificates

• root-ca - includes a self-signed digital certificate to sign other certificates by acting as a certificate authority (CA)

• client-ca - includes the public key certificate for the root CA of the SSL client. If this client-ca certificate is created as part of a root-ca, it will be deleted along with the corresponding deletion of the root-ca.

• server-ca - includes the public key certificate for the root CA of the SSL server to which Data ONTAP is a client. If this server-ca certificate is created as part of a root-ca, it will be deleted along with the corresponding deletion of the root-ca.

• client - includes a public key certificate and private key to be used for Data ONTAP as an SSL client

[-subtype <kmip-cert>] - (DEPRECATED)-Certificate Subtype

Note: This parameter has been deprecated in ONTAP 9.6 and may be removed in a future release of Data ONTAP.

This specifies a certificate subtype. This optional parameter can have an empty value (the default). The only valid value as is as follows:

• kmip-cert - this is a Key Management Interoperability Protocol (KMIP) certificate

[-cert-name <text>] - Unique Certificate Name

This specifies the system’s internal identifier for the certificate. It is unique within a Vserver.

Examples

This example deletes a root-ca type digital certificate for a Vserver named vs0 in a company named www.example.com with serial number 4F57D3D1.

cluster1::> security certificate delete -vserver vs0 -common-name www.example.com -ca www.example.com -type root-ca -serial 4F57D3D1

security certificate generate-csr

Generate a Digital Certificate Signing Request

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description

This command generates a digital certificate signing request and displays it on the console. A certificate signing request (CSR or certification request) is a message sent securely to a certificate authority (CA) via any electronic media, to apply for a digital identity certificate.

Parameters

- common-name <FQDN or Custom Common Name> - FQDN or Custom Common Name

This specifies the desired certificate name as a fully qualified domain name (FQDN) or custom common name or the name of a person. The supported characters, which are a subset of the ASCII character set, are as follows:

• Letters a through z, A through Z

• Numbers 0 through 9

• Asterisk (*), period (.), underscore (_) and hyphen (-)
The common name must not start or end with a "-" or a ".". The maximum length is 253 characters.

[-size <size of requested certificate in bits>] - Size of Requested Certificate in Bits
This specifies the number of bits in the private key. The higher the value, the more secure is the key. The default is 2048. Possible values include 512, 1024, 1536 and 2048.

[-country <text>] - Country Name
This specifies the country where the Vserver resides. The country name is a two-letter code. The default is US. Here is the list of country codes: Country Codes

[-state <text>] - State or Province Name
This specifies the state or province where the Vserver resides.

[-locality <text>] - Locality Name
This specifies the locality where the Vserver resides. For example, the name of a city.

[-organization <text>] - Organization Name
This specifies the organization where the Vserver resides. For example, the name of a company.

[-unit <text>] - Organization Unit
This specifies the unit where the Vserver resides. For example, the name of a section or a department within a company.

[-email-addr <mail address>] - Contact Administrator's Email Address
This specifies the email address of the contact administrator for the Vserver.

[-hash-function <hashing function>] - Hashing Function
This specifies the cryptographic hashing function for signing the certificate. The default is SHA256. Possible values include SHA1, SHA256 and MD5.

Examples

This example creates a certificate-signing request with a 2048-bit private key generated by the SHA256 hashing function for use by the Software group in IT at a company whose custom common name is www.example.com, located in Sunnyvale, California, USA. The email address of the contact administrator who manages the Vserver is web@example.com.

```
cluster1::> security certificate generate-csr -common-name www.example.com-size 2048 -country US -state California -locality Sunnyvale -organization IT -unit Software -email-addr web@example.com -hash-function SHA256
```

Certificate Signing Request:
```
-----BEGIN CERTIFICATE REQUEST-----

security certificate install

Install a Digital Certificate

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The security certificate install command installs digital security certificates signed by a certificate authority (CA) and the public key certificate of the root CA. Digital security certificates also include the intermediate certificates to construct the chain for server certificates (the server type), client-side root CA certificates (the client-ca type), or server-side root CA certificates (the server-ca type), with FIPS enabled, the following restrictions apply to the certificate getting installed. server/client/server-ca/client-ca: Key size >= 2048, server/client: Hash function (No MD-5, No SHA-1), server-ca/client-ca: (Intermediate CA), Hash Function (No MD-5, No SHA-1), server-ca/client-ca: (Root CA), Hash Function (No MD-5)

Parameters
-vserver <Vserver Name> - Name of Vserver
This specifies the Vserver that contains the certificate.

-type <type of certificate> - Type of Certificate
This specifies the certificate type. Valid values are the following:
• server - includes server certificates and intermediate certificates.
• client-ca - includes the public key certificate for the root CA of the SSL client
• server-ca - includes the public key certificate for the root CA of the SSL server to which Data ONTAP is a client
• client - includes a self-signed or CA-signed digital certificate and private key to be used for Data ONTAP as an SSL client

[-subtype <kmip-cert>] - (DEPRECATED)-Certificate Subtype

Note: This parameter has been deprecated in ONTAP 9.6 and may be removed in a future release of Data ONTAP.
This specifies a certificate subtype. This optional parameter can have an empty value (the default). The only valid value is as follows:
• kmip-cert - this is a Key Management Interoperability Protocol (KMIP) certificate

[-kmip-server-ip <IP Address>] - (DEPRECATED)-IPv4 and IPv6 address

Note: This parameter is deprecated and might be removed in the future releases of Data ONTAP.
This parameter is applicable only to the kmip-cert subtype. It specifies the IP address of the KMIP server.

[-cert-name <text>] - Unique Certificate Name
This specifies the system’s internal identifier for the certificate. It must be unique within a Vserver. If not provided, it is automatically generated by the system.

Examples

This example installs a CA-signed certificate (along with intermediate certificates) for a Vserver named vs0.

```
cluster1:~> security certificate install -vserver vs0 -type server
Please enter Certificate: Press <Enter> when done
-----BEGIN CERTIFICATE-----
MIIB8TCCZugAwIBAwIBADANBgkqhkiG9w0BAQFAQADBfMRMwEQYDVQQDEwpuZXRh

-----END CERTIFICATE-----

Do you want to continue entering root and/or intermediate certificates {y|n}: n

You should keep a copy of the private key and the CA-signed digital certificate for future reference.

This example installs a CA certificate for client authentication for a Vserver named vs0.

```
cluster1::> security certificate install -vserver vs0 -type client-ca
```

You should keep a copy of the issued certificate and the CA-signed digital certificate for future reference.

This example installs a CA certificate for server authentication for a Vserver named vs0. In this case, Data ONTAP acts as an SSL client.

```
cluster1::> security certificate install -vserver vs0 -type server-ca
```

You should keep a copy of the CA-signed digital certificate for future reference.
security certificate rename

Rename a certificate

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
This command allows the user to modify the system's identifier for an installed digital certificate. It does not alter the certificate itself.

Parameters
- `-vserver <Vserver Name>` - Vserver Name
  This specifies the name of the Vserver on which the certificate exists.

- `-cert-name <text>` - Existing Certificate Name
  This specifies the current system identifier for the certificate.

- `-new-name <text>` - New Certificate Name
  This specifies the desired system identifier for the certificate. It must be unique among certificates in the Vserver.

Examples

cluster1::> security certificate rename -vserver vs0 -cert-name AAAACertificateServices -new-name AAAACertServ

security certificate show

Display Installed Digital Certificates

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
This command displays information about the installed digital certificates. Some details are displayed only when you use the command with the -instance parameter.

Parameters

{-fields <fieldname>, ...} 
If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.
If you specify the `instance` parameter, the command displays detailed information about all fields.

`[-vserver <Vserver Name>]` - Name of Vserver
Selects the Vserver whose digital certificates you want to display.

`[-common-name <FQDN or Custom Common Name>]` - FQDN or Custom Common Name
Selects the certificates that match this parameter value.

`[-serial <text>]` - Serial Number of Certificate
Selects the certificates that match this parameter value.

`[-ca <text>]` - Certificate Authority
Selects the certificates that match this parameter value.

`[-type <type of certificate>]` - Type of Certificate
Selects the certificates that match this parameter value.

`[-subtype <kmip-cert>]` - (DEPRECATED) Certificate Subtype

Note: This parameter has been deprecated in ONTAP 9.6 and may be removed in a future release of Data ONTAP.
Selects the certificate subtype that matches the specified value. The valid values are as follows:

- `kmip-cert` - this is a Key Management Interoperability Protocol (KMIP) certificate

`[-cert-name <text>]` - Unique Certificate Name
This specifies the system's internal identifier for the certificate. It is unique within a Vserver.

`[-size <size of requested certificate in bits>]` - Size of Requested Certificate in Bits
Selects the certificates that match this parameter value.

`[-start <Date>]` - Certificate Start Date
Selects the certificates that match this parameter value.

`[-expiration <Date>]` - Certificate Expiration Date
Selects the certificates that match this parameter value.

`[-public-cert <certificate>]` - Public Key Certificate
Selects the certificates that match this parameter value.

`[-country <text>]` - Country Name
Selects the certificates that match this parameter value.

`[-state <text>]` - State or Province Name
Selects the certificates that match this parameter value.

`[-locality <text>]` - Locality Name
Selects the certificates that match this parameter value.

`[-organization <text>]` - Organization Name
Selects the certificates that match this parameter value.

`[-unit <text>]` - Organization Unit
Selects the certificates that match this parameter value.

`[-email-addr <mail address>]` - Contact Administrator's Email Address
Selects the certificates that match this parameter value.

`[-protocol <protocol>]` - Protocol
Selects the certificates that match this parameter value.
[-hash-function <hashing function>] - Hashing Function
Selects the certificates that match this parameter value.

[-self-signed (true|false)] - Self-Signed Certificate
Selects the certificates that match this parameter value.

security certificate show-generated
Display ONTAP generated certificates

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
This command displays information about the Data ONTAP generated digital digital certificates. Some details are displayed only when you use the command with the -instance parameter.
Parameters

`[-fields <fieldname>, ...]`
If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

`[-instance]`
If you specify the `-instance` parameter, the command displays detailed information about all fields.

`[-vserver <Vserver Name>]` - Name of Vserver
Selects the Vserver whose digital certificates you want to display.

`[-common-name <FQDN or Custom Common Name>]` - FQDN or Custom Common Name
Selects the certificates that match this parameter value.

`[-serial <text>]` - Serial Number of Certificate
Selects the certificates that match this parameter value.

`[-ca <text>]` - Certificate Authority
Selects the certificates that match this parameter value.

`[-type <type of certificate>]` - Type of Certificate
Selects the certificates that match this parameter value.

`[-subtype <kmip-cert>]` - (DEPRECATED)-Certificate Subtype

Note: This parameter has been deprecated in ONTAP 9.6 and may be removed in a future release of Data ONTAP.
Selects the certificate subtype that matches the specified value. The valid values are as follows:
- `kmip-cert` - this is a Key Management Interoperability Protocol (KMIP) certificate

`[-cert-name <text>]` - Unique Certificate Name
This specifies the system’s internal identifier for the certificate. It is unique within a Vserver.

`[-size <size of requested certificate in bits>]` - Size of Requested Certificate in Bits
Selects the certificates that match this parameter value.

`[-start <Date>]` - Certificate Start Date
Selects the certificates that match this parameter value.

`[-expiration <Date>]` - Certificate Expiration Date
Selects the certificates that match this parameter value.

`[-public-cert <certificate>]` - Public Key Certificate
Selects the certificates that match this parameter value.

`[-country <text>]` - Country Name
Selects the certificates that match this parameter value.

`[-state <text>]` - State or Province Name
Selects the certificates that match this parameter value.

`[-locality <text>]` - Locality Name
Selects the certificates that match this parameter value.

`[-organization <text>]` - Organization Name
Selects the certificates that match this parameter value.

`[-unit <text>]` - Organization Unit
Selects the certificates that match this parameter value.
[-email-addr <mail address>] - Contact Administrator's Email Address

Selects the certificates that match this parameter value.

[-protocol <protocol>] - Protocol

Selects the certificates that match this parameter value.

[-hash-function <hashing function>] - Hashing Function

Selects the certificates that match this parameter value.

[-self-signed {true|false}] - Self-Signed Certificate

Selects the certificates that match this parameter value.

security certificate show-truststore

Display default truststore certificates

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
This command displays information about the default CA certificates that come pre-installed with Data ONTAP. Some details are displayed only when you use the command with the -instance parameter.

Parameters

{ [-fields <fieldname>,...]  
  If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.  
}  

{ [-instance]  
  If you specify the -instance parameter, the command displays detailed information about all fields.  
}  

[-vserver <Vserver Name>] - Name of Vserver
Selects the Vserver whose digital certificates you want to display.

[-common-name <FQDN or Custom Common Name>] - FQDN or Custom Common Name
Selects the certificates that match this parameter value.

[-serial <text>] - Serial Number of Certificate
Selects the certificates that match this parameter value.

[-ca <text>] - Certificate Authority
Selects the certificates that match this parameter value.

[-type <type of certificate>] - Type of Certificate
Selects the certificates that match this parameter value.

[-subtype <kmip-cert>] - (DEPRECATED)-Certificate Subtype

  Note: This parameter has been deprecated in ONTAP 9.6 and may be removed in a future release of Data ONTAP.
Selects the certificate subtype that matches the specified value. The valid values are as follows:

  • kmip-cert - this is a Key Management Interoperability Protocol (KMIP) certificate

[-cert-name <text>] - Unique Certificate Name
This specifies the system’s internal identifier for the certificate. It is unique within a Vserver.

[-size <size of requested certificate in bits>] - Size of Requested Certificate in Bits
Selects the certificates that match this parameter value.

[-start <Date>] - Certificate Start Date
Selects the certificates that match this parameter value.

[-expiration <Date>] - Certificate Expiration Date
Selects the certificates that match this parameter value.

[-public-cert <certificate>] - Public Key Certificate
Selects the certificates that match this parameter value.

[-country <text>] - Country Name
Selects the certificates that match this parameter value.
The examples below display information about the pre-installed truststore digital certificates.

security certificate show-user-installed

Display user installed certificates

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
This command displays information about the user installed digital certificates. Some details are displayed only when you use the command with the -instance parameter. In systems upgraded to Data ONTAP 9.4 or later, existing Data ONTAP generated certificates will also be shown as part of this command.

Parameters

[-fields <fieldname>, ...]
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

[-instance ]
If you specify the -instance parameter, the command displays detailed information about all fields.

[-vserver <Vserver Name>] - Name of Vserver
Selects the Vserver whose digital certificates you want to display.

[-common-name <FQDN or Custom Common Name>] - FQDN or Custom Common Name
Selects the certificates that match this parameter value.

[-serial <text>] - Serial Number of Certificate
Selects the certificates that match this parameter value.

[-ca <text>] - Certificate Authority
Selects the certificates that match this parameter value.

[-type <type of certificate>] - Type of Certificate
Selects the certificates that match this parameter value.

[-subtype <kmip-cert>] - (DEPRECATED)-Certificate Subtype
Note: This parameter has been deprecated in ONTAP 9.6 and may be removed in a future release of Data ONTAP.
Selects the certificate subtype that matches the specified value. The valid values are as follows:

• kmip-cert - this is a Key Management Interoperability Protocol (KMIP) certificate

[-cert-name <text>] - Unique Certificate Name
This specifies the system’s internal identifier for the certificate. It is unique within a Vserver.

[-size <size of requested certificate in bits>] - Size of Requested Certificate in Bits
Selects the certificates that match this parameter value.

[-start <Date>] - Certificate Start Date
Selects the certificates that match this parameter value.
[-expiration <Date>] - Certificate Expiration Date
   Selects the certificates that match this parameter value.

[-public-cert <certificate>] - Public Key Certificate
   Selects the certificates that match this parameter value.

[-country <text>] - Country Name
   Selects the certificates that match this parameter value.

[-state <text>] - State or Province Name
   Selects the certificates that match this parameter value.

[-locality <text>] - Locality Name
   Selects the certificates that match this parameter value.

[-organization <text>] - Organization Name
   Selects the certificates that match this parameter value.

[-unit <text>] - Organization Unit
   Selects the certificates that match this parameter value.

[-email-addr <mail address>] - Contact Administrator's Email Address
   Selects the certificates that match this parameter value.

[-protocol <protocol>] - Protocol
   Selects the certificates that match this parameter value.

[-hash-function <hashing function>] - Hashing Function
   Selects the certificates that match this parameter value.

[-self-signed {true|false}] - Self-Signed Certificate
   Selects the certificates that match this parameter value.

Examples

The examples below display information about user installed digital certificates.

security certificate show on page 478

security certificate sign

Sign a Digital Certificate using Self-Signed Root CA

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
This command signs a digital certificate signing request and generates a certificate using a Self-Signed Root CA certificate in either PEM or PKCS12 format. You can use the security certificate generate-csr command to generate a digital certificate signing request.

Parameters

-vserver <Vserver Name> - Name of Vserver
This specifies the name of the Vserver on which the signed certificate will exist.

-ca <text> - Certificate Authority to Sign
This specifies the name of the Certificate Authority that will sign the certificate.

-ca-serial <text> - Serial Number of CA Certificate
This specifies the serial number of the Certificate Authority that will sign the certificate.

[-expire-days <integer>] - Number of Days until Expiration
This specifies the number of days until the signed certificate expires. The default value is 365 days. Possible values are between 1 and 3652.

[-format <certificate format>] - Certificate Format
This specifies the format of signed certificate. The default value is PEM. Possible values include PEM and PKCS12.

[-destination ((ftp|http)://(hostname|IPv4 Address|'IPv6 Address')...) - Where to Send File
This specifies the destination to upload the signed certificate. This option can only be used when the format is PKCS12.

[-hash-function <hashing function>] - Hashing Function
This specifies the cryptographic hashing function for the self-signed certificate. The default value is SHA256. Possible values include SHA1, SHA256 and MD5.

Examples
This example signs a digital certificate for a Vserver named vs0 using a Certificate Authority certificate that has a ca of www.ca.com and a ca-serial of 4F4EB629 in PEM format using the SHA256 hashing function.

Commands: Manual Page Reference
security certificate ca-issued commands
Show Digital Certificates Issued by Self-Signed CA

security certificate ca-issued revoke
Revoke a Digital Certificate

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
This command revokes a digital certificate signed by a Self-Signed Root CA.

Parameters
- vserver <Vserver Name> - Vserver
  This specifies the name of the Vserver on which the certificate is stored.

- serial <text> - Serial Number of Certificate
  This specifies the serial number of the certificate.

- ca <text> - Certificate Authority
  This specifies the name of the Certificate Authority whose certificate will be revoked.

- ca-serial <text> - Serial Number of CA Certificate
  This specifies the serial number of Certificate Authority.

[[-common-name <FQDN or Custom Common Name>] - FQDN or Custom Common Name]
  This specifies a fully qualified domain name (FQDN) or custom common name or the name of a person. This field is optional if ca-serial is specified.

Examples
This example revokes a signed digital certificate for a Vserver named vs0 with serial as 4F5A2DF2 for a Certificate Authority certificate that has a ca of www.ca.com and a ca-serial of 4F4EB629.

    cluster1::> security certificate ca-issued revoke -vserver vs0 -serial 4F5A2DF2 -ca www.ca.com -ca-serial 4F4EB629

security certificate ca-issued show
Display CA-Issued Digital Certificates

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
This command displays the following information about the digital certificates issued by the self-signed root-ca:

- Vserver
• Serial number of certificate
• FQDN or custom common name or the name of a person
• Serial number of CA certificate
• Status (active, revoked)
• Certificate Authority
• Expiration date
• Revocation date

To display more details, run the command with the -instance parameter. This will add the following information:

• Country name
• State or province name
• Locality name
• Organization name
• Organization unit
• Contact administrator's email address

Parameters

[-fields <fieldname>, ...]
  If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

[-instance]
  If you specify the -instance parameter, the command displays detailed information about all fields.

[-vserver <Vserver Name>] - Vserver
  Selects the certificates that match this parameter value.

[-serial <text>] - Serial Number of Certificate
  Selects the certificates that match this parameter value.

[-ca <text>] - Certificate Authority
  Selects the certificates that match this parameter value.

[-ca-serial <text>] - Serial Number of CA Certificate
  Selects the certificates that match this parameter value.

[-common-name <FQDN or Custom Common Name>] - FQDN or Custom Common Name
  Selects the certificates that match this parameter value.

[-status <status of certificate>] - Status of Certificate
  Selects the certificates that match this parameter value. Possible values include active and revoked.

[-expiration <Date>] - Certificate Expiration Date
  Selects the certificates that match this parameter value.

[-revocation <Date>] - Certificate Revocation Date
  Selects the certificates that match this parameter value.

[-country <text>] - Country Name (2 letter code)
  Selects the certificates that match this parameter value.
Examples
The examples below display information about CA issued digital certificates.

Example 1
cluster1::> security certificate ca-issued show

<table>
<thead>
<tr>
<th>Vserver</th>
<th>Serial Number</th>
<th>Common Name</th>

Show Commands

truststore
Field description for all the certificate show commands.

security certificate truststore show
Display default truststore certificates

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.
Description
This command displays information about the default CA certificates that come pre-installed with Data ONTAP. Some details are displayed only when you use the command with the -instance parameter.

Parameters
{ [-fields <fieldname>, ...]  
  If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.  
  [-instance]}  
  If you specify the -instance parameter, the command displays detailed information about all fields.  

[-vserver <Vserver Name>] - Name of Vserver  
  Selects the Vserver whose digital certificates you want to display.  

[-common-name <FQDN or Custom Common Name>] - FQDN or Custom Common Name  
  Selects the certificates that match this parameter value.  

[-serial <text>] - Serial Number of Certificate  
  Selects the certificates that match this parameter value.  

[-ca <text>] - Certificate Authority  
  Selects the certificates that match this parameter value.  

[-type <type of certificate>] - Type of Certificate  
  Selects the certificates that match this parameter value.  

[-subtype <kmip-cert>] - (DEPRECATED)-Certificate Subtype  
  Selects the certificate subtype that matches the specified value. The valid values are as follows:  
  • kmip-cert - this is a Key Management Interoperability Protocol (KMIP) certificate  

[-cert-name <text>] - Unique Certificate Name  
  This specifies the system's internal identifier for the certificate. It is unique within a Vserver.  

[-size <size of requested certificate in bits>] - Size of Requested Certificate in Bits  
  Selects the certificates that match this parameter value.  

[-start <Date>] - Certificate Start Date  
  Selects the certificates that match this parameter value.  

[-expiration <Date>] - Certificate Expiration Date  
  Selects the certificates that match this parameter value.  

[-public-cert <certificate>] - Public Key Certificate  
  Selects the certificates that match this parameter value.  

[-country <text>] - Country Name  
  Selects the certificates that match this parameter value.  

[-state <text>] - State or Province Name  
  Selects the certificates that match this parameter value.  

[-locality <text>] - Locality Name  
  Selects the certificates that match this parameter value.  

[-organization <text>] - Organization Name  
  Selects the certificates that match this parameter value.
[-unit <text>] · Organization Unit

Selects the certificates that match this parameter value.

[-email-addr <mail address>] · Contact Administrator's Email Address

Selects the certificates that match this parameter value.

[-protocol <protocol>] · Protocol

Selects the certificates that match this parameter value.

[-hash-function <hashing function>] · Hashing Function

Selects the certificates that match this parameter value.

[-self-signed {true|false}] · Self-Signed Certificate

Selects the certificates that match this parameter value.

Examples

The examples below display information about the pre-installed truststore digital certificates.

```
classeter1::> security certificate truststore show

security config commands
Manage Cluster Security Configuration

security config modify
Modify Security Configuration Options

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
The security config modify command modifies the existing cluster-wide security configuration. If you enable FIPS-compliant mode, the cluster will automatically select only compliant TLS protocols (currently TLSv1.2 and TLSv1.1). Non-compliant protocols are not enabled when FIPS-compliant mode is disabled. Use the -supported-protocols parameter to include or exclude TLS protocols independently from the FIPS mode. All protocols at or above the lowest version specified will be enabled, even those not explicitly specified. By default, FIPS mode is disabled, and Data ONTAP supports the TLSv1.2, TLSv1.1 and TLSv1 protocols. For backward compatibility, Data ONTAP supports adding SSLv3 to the supported-protocols list when FIPS mode is disabled. Use the -supported-ciphers parameter to configure only AES, or AES and 3DES, or disable weak ciphers such as RC4 by specifying !RC4. By default the supported-cipher setting is ALL:!LOW:!aNULL:!EXP:!eNULL. This setting means that all supported cipher suites for the protocols are enabled, except the ones with no authentication, no encryption, no exports, and low encryption cipher suites (currently those using 64-bit or 56-bit encryption algorithms). Select a cipher suite which is available with the corresponding selected protocol. An invalid configuration may cause some functionality to fail to operate properly. Refer to "https://www.openssl.org/docs/apps/ciphers.html" published by the OpenSSL software foundation for the correct cipher string syntax. After modifying the security configuration, reboot all the nodes manually.

Parameters
- -interface <SSL> - FIPS-Compliant Interface
  Selects the FIPS-compliant interface. Default is SSL.

  [-is-fips-enabled (true|false)] - FIPS Mode
  Enables or disables FIPS-compliant mode for the entire cluster. Default is false.

  [-supported-protocols (TLSv1.2|TLSv1.1|TLSv1|SSLv3),...] - Supported Protocols
  Selects the supported protocols for the selected interface. Default is TLSv1.2, TLSv1.1, TLSv1

  [-supported-ciphers <Cipher String>] - Supported Ciphers
  Selects the supported cipher suites for the selected interface. Default is ALL:!LOW:!aNULL:!EXP:!eNULL.

Examples
The following command enables FIPS mode in the cluster. (Default setting for FIPS mode is false)

    cluster1::> security config modify -interface SSL -is-fips-enabled true

The following command modifies supported protocols to TLSv1.2 and TLSv1.1 in the cluster. (Default setting for supported protocols is TLSv1.2, TLSv1.1, TLSv1)

    cluster1::*> security config modify -interface SSL -supported-protocols TLSv1.2, TLSv1.1

The following command modifies supported ciphers to ALL:!LOW:!aNULL:!EXP:!eNULL:!RC4 in the cluster. (Default setting for supported ciphers is ALL:!LOW:!aNULL:!EXP:!eNULL)
security config modify

-cluster1::*> security config modify -interface SSL -supported-ciphers ALL:!LOW:!aNULL:!EXP:!eNULL:RC4

security config show

Display Security Configuration Options

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
The security config show command displays the security configurations of the cluster in advanced privilege mode.

Default values are as follows:

• SSL FIPS mode: disabled
• Supported protocols: TLSv1.2, TLSv1.1, TLSv1
• Supported ciphers: ALL:!LOW:!aNULL:!EXP:!eNULL

The default cipher suites represent all suites for the listed protocols except those that have no authentication, no encryption, no exports, and low encryption (below 64 or 56 bit).

Enabling FIPS mode will cause the entire cluster to use FIPS-compliant crypto operations only.

Use the security config modify command to change the protocols and ciphers that the cluster will support. When all the nodes in the cluster are updated with the modified settings, the cluster security config ready value will be shown as yes.

Parameters

{[-fields <fieldname>, ...]
  If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.
}

{[-instance ]
  If you specify the -instance parameter, the command displays detailed information about all fields.
}

[-interface <SSL>] - FIPS-Compliant Interface
Displays configurations that match the specified value for the interface.

[-is-fips-enabled {true|false}] - FIPS Mode
Display configurations that match the specified value for FIPS mode.

[-supported-protocols {TLSv1.2|TLSv1.1|TLSv1|SSLv3}, ...] - Supported Protocols
Displays configurations that match the specified protocols.

[-supported-ciphers <Cipher String>] - Supported Ciphers
Displays the configurations that match the specified supported ciphers.

Examples

The following example shows the default security configurations for a cluster.

<table>
<thead>
<tr>
<th>Interface</th>
<th>Cluster Security</th>
</tr>
</thead>
<tbody>
<tr>
<td>SSL</td>
<td></td>
</tr>
<tr>
<td>false</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>

**security config ocsp commands**

Manage OCSP Support for SSL Applications

**security config ocsp disable**

Disable OCSP for one or more selected applications

**Availability:** This command is available to cluster administrators at the advanced privilege level.

**Description**

The `security config ocsp disable` command disables the OCSP-based certificate status check for applications supporting SSL/TLS communications. For more information about the OCSP-based certificate status check for applications supporting SSL/TLS communications, see the `security config ocsp show` command.

**Parameters**

- `-application <Application supporting SSL/TLS protocol>,...` - Application Name

  Use this parameter to specify the application to disable the OCSP support. To disable all applications, the value `all` can be used. Note: You cannot specify the value `all` with other applications.

**Examples**

The following example disables the OCSP support for AutoSupport and EMS applications:

```
cluster1::*> security config ocsp disable -application autosupport,ems
```

```
autosupport       false
audit_log         true
fabricpool        true
ems               false
kmip              true
ldap              true
```

6 entries were displayed.

The following example disables the OCSP support for all applications:

```
cluster1::*> security config ocsp disable -application all
```

Warning: OCSP will be disabled for all applications. Any previous modifications will be ignored.

Do you want to continue? {y|n}: y

```
cluster1::*> security config ocsp show
Application          OCSP Enabled?
--------------------- -------------
autosupport          false
audit_log            true
fabricpool           true
ems                  false
kmip                 true
ldap                 true
```

6 entries were displayed.
security config ocsp enable

Enable OCSP for one or more selected applications

Availability: This command is available to cluster administrators at the advanced privilege level.

Description

The `security config ocsp enable` command enables the OCSP-based certificate status check for applications supporting SSL/TLS communications. For more information about the OCSP-based certificate status check for applications supporting SSL/TLS communications, see the `security config ocsp show` command.

Parameters

- `-application <Application supporting SSL/TLS protocol>,...` - List of Applications

Use this parameter to specify the application to enable the OCSP support. To enable all applications, the value 'all' can be used. Note: You cannot specify the value 'all' with other applications.

Examples

The following example enables the OCSP support for AutoSupport and EMS applications:

```
cluster1::*> security config ocsp enable -application autosupport,ems
```

```
cluster1::> security config ocsp show
Application          OCSP Enabled?
-------------------- -------------
autosupport          true
audit_log            false
fabricpool           false
ems                  true
kmip                 false
ldap                 false
6 entries were displayed.
```

The following example enables the OCSP support for all applications:

```
cluster1::*> security config ocsp enable -application all
Warning: OCSP will be enabled for all applications. Any previous modifications will be ignored.
Do you want to continue? {y|n}: y
```

```
cluster1::*> security config ocsp show
Application          OCSP Enabled?
-------------------- -------------
autosupport          true
audit_log            true
fabricpool           true
ems                  true
kmip                 true
ldap                 true
6 entries were displayed.
```
security config ocsp show

Show Online Certificate Status Protocol (OCSP) settings

Availability: This command is available to cluster administrators at the advanced privilege level.

Description

The `security config ocsp show` command displays the support status of the OCSP-based certificate status check for applications supporting SSL/TLS communications. If the OCSP support is enabled for an application, this check is done in addition to the certificate chain validation as part of the SSL handshake process. The OCSP-based certificate status check is done for all the certificates in the chain, provided that each certificate has the OCSP URI access points mentioned in them. If no access points are specified, the OCSP-based certificate revocation status check is ignored for that certificate and checking continues for the rest of the certificates in the chain.

Parameters

`{ [-fields <fieldname>, ...]`

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

`| [-instance ]}

If you specify the `-instance` parameter, the command displays detailed information about all fields.

`[-application <Application supporting SSL/TLS protocol>] - Application Name`

Selects the application that matches this parameter value. Applications include:

- autosupport - AutoSupport
- audit_log - Audit Logging
- fabricpool - External capacity tiers
- ems - Event Management System
- kmip - Key Management Interoperability Protocol
- ldap_nis_namemap - Lightweight Directory Access Protocol - NIS and Name Mapping (query Unix user, group, netgroup and name mapping information)

`[-is-ocsp-enabled (true|false)] - Is OCSP-based Certificate Status Check Enabled?`

Selects the application that matches this parameter value.

Examples

The following example displays the OCSP support for the applications supporting SSL/TLS communications:

```
cluster1::> security config ocsp show
Application          OCSP Enabled?
--------------------  -------------
autosupport          true
audit_log            false
fabricpool           false
```
The following example displays the OCSP support for AutoSupport:

```
cluster1::*> security config ocsp show -application autosupport

Application Name: autosupport
Is OCSP-based Certificate Status Check Enabled?: true
```

### security config status commands

The status directory

### security config status show

Display Security Configuration Status

**Availability:** This command is available to `cluster` administrators at the *advanced* privilege level.

**Description**

The `security config status show` command displays the required reboot status of the nodes in the cluster after security configuration settings have been modified using the `security config modify` command. Use this command to monitor the status of the required reboot process. When all nodes have rebooted, the cluster is ready to use the new security configuration settings.

**Parameters**

- `/[-fields <fieldname>, ...]`
  
  If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

- `/[-instance]`
  
  If you specify the `-instance` parameter, the command displays detailed information about all fields.

- `/[-node {<nodename>|local}] - Node Name`
  
  Select the node whose reboot-status you want to display.

- `/[-reboot-needed {true|false}] - Reboot Needed`
  
  reboot-needed status of the node that tells if the node requires a reboot for security configuration to take effect.

### Examples

The following example displays the status of a configuration change in a four-node cluster.

```
cluster1::> security config status show

Nodes in Cluster Reboot Needed
--------------------- -------------------
node1                 true
node2                 true
node3                 false
node4                 false
4 entries were displayed.
```

The following example shows the output of the command after the cluster reboot process is complete.

*security config modify* on page 494

**security key-manager commands**

Manage Key Management Servers

**security key-manager add**

(DEPRECATED)-Add a key management server

**Availability:** This command is available to cluster administrators at the *admin* privilege level.

**Description**

*Note:* This command is deprecated and may be removed in a future release. Use *security key-manager external add-servers* instead.

This command adds a key management server at the indicated IP address to its list of four possible active key management servers. The command fails if there are already four key management servers configured. This command is not supported when onboard key management is enabled.

**Parameters**

- **-address <IP Address>** - IP Address

  This parameter specifies the IP address of the key management server you want to use to store keys.

- **[-server-port <integer>]** - Server TCP Port

  This parameter specifies the TCP port on which the key management server will listen for incoming connections.

**Examples**

The following example adds the key management server with address 10.233.1.98, listening for incoming connections on the default TCP port 5696, to the list of key management servers used by the external key manager:

```
cluster-1::> security key-manager add -address 10.233.1.98
```

The following example adds the key management server with address 10.233.1.98, listening for incoming connections on TCP port 15696, to the list of key management servers used by the external key manager:

```
cluster-1::> security key-manager add -address 10.233.1.198 -server-port 15696
```
security key-manager create-key

(DEPRECATED)-Create a new authentication key

Availability: This command is available to cluster administrators at the admin privilege level.

Description

Note: This command is deprecated and may be removed in a future release. Use security key-manager key create instead.

This command creates a new authentication key (AK) and stores it on the configured key management servers. The command fails if the configured key management servers are already storing more than 128 AKs. If command fails due to more than 128 keys in cluster, delete unused keys on your key management servers and try the command again. This command is not supported when onboard key management is enabled.

Parameters

[-key-tag <text>] - Key Tag

This parameter specifies the key tag that you want to associate with the new authentication key (AK). The default value is the node name. This parameter can be used to help identify created authentication keys (AKs). For example, the key-manager query command key-tag parameter can be used to query for a specific key-tag value.

[-prompt-for-key {true|false}] - Prompt for Authentication Passphrase

If you specify this parameter as true, the command prompts you to enter an authentication passphrase manually instead of generating it automatically. For security reasons, the authentication passphrase you entered is not displayed at the command prompt. You must enter the authentication passphrase a second time for verification. To avoid errors, copy and paste authentication passphrases electronically instead of entering them manually. Data ONTAP saves the resulting authentication key/key ID pair automatically on the configured key management servers.

Examples

The following example creates an authentication key with the node name as the default key-tag value:

```
cluster-1::> security key-manager create-key
Verifying requirements...
Node: node1
Creating authentication key...
Authentication key creation successful.
Key ID: 00000000000000000200000000000100D0F7C2462D626B739FE81B89F29A092F.
Node: node2
Key manager restore operation initialized.
Successfully restored key information.
```

The following example creates an authentication key with key-tag "disk1-key":

```
cluster-1::> security key-manager create-key -key-tag disk1-key
Verifying requirements...
Node: node1
Creating authentication key...
Authentication key creation successful.
Key ID: 00000000000000000200000000000100B8297A6189BC24B9B84C1916ED576857.
```
The following example creates an authentication key with a user-specified authentication passphrase:

```
cluster-1::> security key-manager create-key -prompt-for-key true
Enter a new passphrase::
Reenter the passphrase::
Verifying requirements...
Node: node1
Creating authentication key...
Authentication key creation successful.
Key ID: 00000000000000002000000000106268333F87086D128FBE17D393E5083B.
Node: node2
Key manager restore operation initialized.
Successfully restored key information.
```

Related references

`security key-manager key create` on page 524

**security key-manager delete**

(DEPRECATED)-Delete a key management server

**Availability:** This command is available to `cluster` administrators at the `admin` privilege level.

**Description**

**Note:** This command is deprecated and may be removed in a future release. Use `security key-manager external remove-servers` instead.

This command removes the key management server at the indicated IP address from the list of active key management servers. If the indicated key management server is the sole storage location for any key that is in use by Data ONTAP, you will be unable to remove the key server. This command is not supported when onboard key management is enabled.

**Parameters**

`-address <IP Address>` - IP Address

This parameter specifies the IP address of the key management server you want to remove from use.

**Examples**

The following example removes the key server at IP address 10.233.1.198 from the set of configured key management servers:

```
cluster-1::> security key-manager delete -address 10.233.1.198
```

Related references

`security key-manager external remove-servers` on page 517
security key-manager delete-key-database

(DEPRECATED)-Deletes the key hierarchy for onboard key manager

Availability: This command is available to cluster administrators at the advanced privilege level.

Description

Note: This command is deprecated and might be removed in a future release. Use security key-manager onboard disable instead.

The security key-manager delete-key-database command permanently deletes the onboard key-management configuration from all nodes of the cluster.

Examples

The following example deletes the onboard key-management configuration from all nodes of the cluster:

```
cluster-1::*> security key-manager delete-key-database
Warning: This command will permanently delete all keys from onboard key management.
Do you want to continue? {y|n}: y
```

Related references

security key-manager onboard disable on page 530

security key-manager delete-kmip-config

(DEPRECATED)-Deletes the KMIP configuration

Availability: This command is available to cluster administrators at the advanced privilege level.

Description

Note: This command is deprecated and may be removed in a future release. Use security key-manager external disable instead.

The security key-manager delete-kmip-config command permanently deletes the Key Management Interoperability Protocol (KMIP) server configuration from all nodes of the cluster.

Note: The keys stored by the external KMIP servers cannot be deleted by Data ONTAP, and must be deleted by using external tools.

Examples

The following example deletes the KMIP-server configuration from all nodes of the cluster:

```
cluster-1::*> security key-manager delete-kmip-config
Warning: This command will permanently delete the KMIP-server configuration from all nodes of the cluster.
Do you want to continue? {y|n}: y
The KMIP-server configuration has been successfully deleted from all nodes of the cluster. The keys stored by the external KMIP servers cannot be deleted by Data ONTAP, and must be deleted by using external tools.
```

*security key-manager external disable* on page 515

security key-manager prepare-to-downgrade

(DEPRECATED)-Disables onboard keymanagement features for unsupported versions

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

**Description**

**Note:** This command is deprecated and might be removed in a future release.

The *security key-manager prepare-to-downgrade* command disables the onboard key management features that are not supported in releases prior to ONTAP 9.1.0. The features that are disabled are onboard key management support for Metrocluster configurations and Volume Encryption (VE).

### Examples

The following example disables the onboard key management support for Metrocluster configurations and Volume Encryption (VE):

```
cluster1::*> security key-manager prepare-to-downgrade
```

security key-manager query

(DEPRECATED)-Displays the key IDs stored in a key management server.

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**

**Note:** This command is deprecated and may be removed in a future release. Use *security key-manager key query* instead.

This command displays the IDs of the keys that are stored on the key management servers. This command does not update the key tables on the node. To refresh the key tables on the nodes with the key management server key tables, run the *security key-manager restore* command. This command is not supported when onboard key management is enabled.

**Parameters**

```
([-fields \<fieldname>, ...]
    If you specify the `-fields \<fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

    | [-instance ]
    If you specify the `-instance` parameter, the command displays detailed information about all fields.

    [\-node \(<nodename>|local\)] - Node
    This parameter specifies the name of the node that queries the specified key management servers. If this parameter is not specified, then all nodes will query the specified key management servers.

    [\-address <IP Address>] - IP Address
    This parameter specifies the IP address of the key management server that you want to query.

    [\-key-id \<key id>] - Key ID
    If you specify this parameter, then the command displays only the key IDs that match the specified value.
```
[-key-tag <text>] - Key Tag

If you specify this parameter, then the command displays only the key IDs that match the specified value. The key-tag for Volume Encryption Keys (VEKs) is set to the UUID of the encrypted volume.

[-key-type <Key Usage Type>] - Key Type

If you specify this parameter, then the command displays only the key IDs that match the specified value.

[-count <integer>] - (DEPRECATED)-Key Server's Total Key Count

The value count is deprecated and may be removed in a future release of Data ONTAP. This parameter specifies the total number of keys stored in the key management servers. If you specify this parameter, then the command displays only the key IDs retrieved from the key management servers whose total key count matches the specified count number.

[-restored {yes|no}] - Key/Key ID Pair Present in Node's Key Table?

This parameter specifies whether the key corresponding to the displayed key ID is present in the specified node's internal key table. If you specify 'yes' for this parameter, then the command displays the key IDs of only those keys that are present in the system's internal key table. If you specify 'no' for this parameter, then the command displays the key IDs of only those keys that are not present in the system's internal key table.

[-key-manager-server-status {available|not-responding|unknown}] - Command Error Code

This parameter specifies the connectivity status of the key management server. If you specify this parameter, then the command displays only the key IDs retrieved from the key management servers with specified status.

Examples

The following example shows all the keys on all configured key servers, and whether those keys have been restored for all nodes in the cluster:

```bash
cluster-1::> security key-manager query

Node: node1
Key Manager: 10.0.0.10
Server Status: available

Key Tag                               Key Type  Restored
------------------------------------  --------  --------
nod1                                 NSE-AK    yes
Key ID: 000000000000000002000000000001001d71f3b2468d7e16a6e6972d3e664520000000000000000
301a4e57-9efb-11e7-b2bc-0050569c227f  VEK       yes
Key ID: 000000000000000002000000000005004d03aca5b72cd20b2f83ea1531c605e00000000000000

Node: node2
Key Manager: 10.0.0.10
Server Status: available

Key Tag                               Key Type  Restored
------------------------------------  --------  --------
nod1                                 NSE-AK    yes
Key ID: 000000000000000002000000000001001d71f3b2468d7e16a6e6972d3e664520000000000000000
301a4e57-9efb-11e7-b2bc-0050569c227f  VEK       no
Key ID: 000000000000000002000000000005004d03aca5b72cd20b2f83ea1531c605e00000000000000
If any listed keys have "no" in the "Restored" column, run "security key-manager restore" to restore those keys.
```

The following example shows all keys stored on the key server with address "10.0.0.10" from node "node1" with key-tag "nod1":

```bash
cluster-1::> security key-manager query -address 10.0.0.10 -node node1 -key-tag nod1

Node: node1
Key Manager: 10.0.0.10
Server Status: available
```
If any listed keys have "no" in the "Restored" column, run "security key-manager restore" to restore those keys.

The following example shows the Volume Encryption Key (VEK) with key-tag (i.e., volume UUID) "301a4e57-9efb-11e7-b2bc-0050569c227f" on nodes where that key has not been restored:

```
cluster-l::*> security key-manager query -key-type VEK -key-tag 301a4e57-9efb-11e7-b2bc-0050569c227f -restored no

Node: node2
Key Manager: 10.0.0.10
Server Status: available

<table>
<thead>
<tr>
<th>Key Tag</th>
<th>Key Type</th>
<th>Restored</th>
</tr>
</thead>
<tbody>
<tr>
<td>301a4e57-9efb-11e7-b2bc-0050569c227f</td>
<td>VEK</td>
<td>no</td>
</tr>
</tbody>
</table>

Key ID: 0000000000000002000000000000000000000000000000000000000000000000
```

If any listed keys have "no" in the "Restored" column, run "security key-manager restore" to restore those keys.

**security key-manager restore**

(DEPRECATED)-Restore the key ID pairs from the key management servers.

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**

- **Note:** This command is deprecated and may be removed in a future release. Use `security key-manager external restore` instead.

This command retrieves and restores any current unrestored keys associated with the storage controller from the specified key management servers. This command is not supported when onboard key management is enabled.

**Parameters**

- `-fields <fieldname>,...`
  
  If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

- `[-instance]]`
  
  If you specify the `-instance` parameter, the command displays detailed information about all fields.

- `[-node <nodename> | local]] - Node`
  
  This parameter specifies the name of the node that is to load the key IDs into its internal key table. If not specified, all nodes retrieve keys into their internal key table.
[-address <IP Address>] - IP Address

If this parameter is specified, the command restores only from key management server at the specified IP address. If not specified the command restores from all available key management servers.

[-key-id <key id>] - Key ID

If this parameter is specified, the command restores only the specified key IDs.

[-key-tag <text>] - Key Tag

This parameter specifies the value associated with the key ID pair at the time of their creation. If specified, restore only key ID pairs associated with the specified key tag. If not specified, all key ID pairs for the cluster are retrieved.

[-count <integer>] - (DEPRECATED)-Key Server's total Key Count

The value count is deprecated and may be removed in a future release of Data ONTAP. This parameter specifies the total number of keys stored in the key management servers. If this parameter is specified, then the command displays only the key IDs retrieved from the key management servers whose total key count matches the specified count number.

[-key-manager-server-status {available|not-responding|unknown}] - Command Error Code

This parameter specifies the connectivity status of the key management server. If you specify this parameter the command displays only the key IDs retrieved from key management servers with specified status.

Examples

The following command restores keys that are currently on a key server but are not stored within the key tables on the cluster:

cluster-l::> security key-manager restore

    Node: node1
    Key Manager: 10.0.0.10
    Server Status: available

    Key IDs
    ------------------------------
    000000000000000002000000000001001d71f3b2468d7e16a6e6972d3e66452000000000000000000
    000000000000000002000000000005004d03aca5b72cd20b2f83eae1531c605e0000000000000000

    Node: node2
    Key Manager: 10.0.0.10
    Server Status: available

    Key IDs
    ------------------------------
    000000000000000002000000000001001d71f3b2468d7e16a6e6972d3e66452000000000000000000
    000000000000000002000000000005004d03aca5b72cd20b2f83eae1531c605e0000000000000000

The following loads any keys that exist on the key servers with IP address 10.0.0.10 with key-tag "node1" that are not currently stored in key tables of the nodes in the cluster. In this example, a key with that key-tag was missing from two nodes in the cluster:

cluster-l::> security key-manager restore -address 10.0.0.10 -key-tag node1

    Node: node1
    Key Manager: 10.0.0.10
    Server Status: available

    Key IDs
    ------------------------------
    000000000000000002000000000001001d71f3b2468d7e16a6e6972d3e66452000000000000000000

    Node: node2
    Key Manager: 10.0.0.10
security key-manager setup

(DEPRECATED)-Configure key manager connectivity

Availability: This command is available to cluster administrators at the admin privilege level.

Description

Note: This command is deprecated and might be removed in a future release. To set up external key manager, use `security key-manager external enable`, and to set up onboard key manager use `security key-manager onboard enable` instead.

The `security key-manager setup` command enables you to configure key management. Data ONTAP supports two mutually exclusive key management methods: external via one or more key management interoperability protocol (KMIP) servers, or internal via an onboard key manager. This command is used to configure an external or internal key manager. When configuring an external key management server, this command records networking information on all node that is used during the boot process to retrieve keys needed for booting from the KMIP servers. For onboard key management, this command prompts you to configure a passphrase to protect internal keys in encrypted form.

This command can also be used to refresh missing onboard keys. For example, if you add a node to a cluster that has onboard key management configured, you will run this command to refresh the missing keys.

For onboard key management in a MetroCluster configuration, if the `security key-manager update-passphrase` command is used to update the passphrase on one site, then run the `security key-manager setup` command with the new passphrase on the partner site before proceeding with any key-manager operations.

Parameters

`[-node <nodename>]` - Node Name

This parameter is used only with onboard key management when a refresh operation is required (see command description). This parameter is ignored when configuring external key management and during the initial setup of onboard key management.

`[-cc-mode-enabled {yes|no}]` - Enable Common Criteria Mode?

When configuring onboard key management, this parameter is used to specify that Common Criteria (CC) mode should be enabled. When CC mode is enabled, you will be required to provide a cluster passphrase that is between 64 and 256 ASCII character long, and you will be required to enter that passphrase each time a node reboots.

`[-sync-metrocluster-config {yes|no}]` - Sync MetroCluster Configuration from Peer

When configuring onboard key management in a MetroCluster configuration, this parameter is used to indicate that the `security key-manager setup` command has been performed on the peer cluster, and that the `security key-manager setup` command on this cluster should import the peer's configuration.

Examples

The following example creates a configuration for external key management:
cluster-1::> security key-manager setup
Welcome to the key manager setup wizard, which will lead you through the steps to add boot information.

Enter the following commands at any time
"help" or "?" if you want to have a question clarified,
"back" if you want to change your answers to previous questions, and
"exit" if you want to quit the key manager setup wizard. Any changes you made before typing "exit" will be applied.

Restart the key manager setup wizard with "security key-manager setup". To accept a default or omit a question, do not enter a value.

Would you like to configure onboard key management? {yes, no} [yes]: no
Would you like to configure the KMIP server environment? {yes, no} [yes]: yes

The following example creates a configuration for onboard key management:

cluster-1::> security key-manager setup
Welcome to the key manager setup wizard, which will lead you through the steps to add boot information.

Enter the following commands at any time
"help" or "?" if you want to have a question clarified,
"back" if you want to change your answers to previous questions, and
"exit" if you want to quit the key manager setup wizard. Any changes you made before typing "exit" will be applied.

Restart the key manager setup wizard with "security key-manager setup". To accept a default or omit a question, do not enter a value.

Would you like to configure onboard key management? {yes, no} [yes]: yes
Enter the cluster-wide passphrase for onboard key management. To continue the configuration, enter the passphrase, otherwise type "exit":
Re-enter the cluster-wide passphrase:
After configuring onboard key management, save the encrypted configuration data in a safe location so that you can use it if you need to perform a manual recovery operation. To view the data, use the "security key-manager backup show" command.

The following example creates a configuration for onboard key management with Common Criteria mode enabled:

cluster-1::> security key-manager setup -cc-mode-enabled yes
Welcome to the key manager setup wizard, which will lead you through the steps to add boot information.

Enter the following commands at any time
"help" or "?" if you want to have a question clarified,
"back" if you want to change your answers to previous questions, and
"exit" if you want to quit the key manager setup wizard. Any changes you made before typing "exit" will be applied.

Restart the key manager setup wizard with "security key-manager setup". To accept a default or omit a question, do not enter a value.

Would you like to configure onboard key management? {yes, no} [yes]: yes
Enter the cluster-wide passphrase for onboard key management. To continue the configuration, enter the passphrase, otherwise type "exit":
Re-enter the cluster-wide passphrase:
After configuring onboard key management, save the encrypted configuration data in a safe location so that you can use it if you need to perform a manual recovery operation. To view the data, use the "security key-manager backup show" command.

Related references

security key-manager external enable on page 515
security key-manager show

(DEPRECATED)-Display key management servers

Availability: This command is available to cluster administrators at the admin privilege level.

Description

Note: This command is deprecated and may be removed in a future release. Use security key-manager external show instead.

This command displays the key management servers configured on the cluster. This command is not supported when onboard key management is enabled.

Parameters

{ [-fields <fieldname>,...]
  
  If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use ‘-fields ?’ to display the fields to specify.

  [-status ]
  
  If you specify this parameter, the command displays the status of each key management server.

  [-instance ]
  
  If you specify the -instance parameter, the command displays detailed information about all fields.

[-node {<nodename>|local}] - Node
  
  This parameter specifies the name of the node that you want to retrieve key management server status for. If parameter is not specified, all nodes will retrieve the key management servers status.

[-address <IP Address>] - IP Address
  
  Shows only a key management server registered with the input address. It is also possible to show multiple key management servers.

[-server-port <integer>] - Server TCP Port
  
  If you specify this parameter, the command displays only key servers listening on this port.

Examples

The following example lists all configured key management servers:

```
cluster-1::> security key-manager show

Node                    Registered Key Manager
----------------------  ---------------------------
node1                   10.225.89.33
node2                   10.225.89.33
```

The following example lists all configured key management servers, the TCP port on which those servers are expected to listen for incoming KMIP connections, and their server status:

```
cluster-1::> security key-manager show -status

Node     Port     Registered Key Manager     Status
---------- ----------- -------------------------------
node1     510        10.225.89.33              
node2     510        10.225.89.33              
node3     510        10.225.89.33              
```
security key-manager show-key-store

Displays the configured key manager key stores.

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description

This command displays the list of configured key managers.

Parameters

\{-fields \<fieldname\>, ...\}

If you specify the \-fields \<fieldname\>, ... parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

\{-instance \}

If you specify the `-instance` parameter, the command displays detailed information about all fields.

\{-vserver \<vserver name\>\} - Vserver

If you specify this parameter, then the command will list the key manager configured for the given Vserver.

\{-key-store \<Key Store\>\} - Key Store

If you specify this parameter, then the command displays only the vservers that have the given key-store configured.

Examples

The following example shows all configured key managers in the cluster. In the example, the admin vservers has onboard key management configured and the data vservers "datavs1" has external key management configured:

```
cluster-1::> security key-manager show-key-store
Vserver   Key Store
---------  ---------
cluster-1  onboard
datavs1   external
```

security key-manager update-passphrase

(DEPRECATED)-Update cluster-wide passphrase

Availability: This command is available to cluster administrators at the advanced privilege level.

Description

Note: This command is deprecated and might be removed in a future release. Use `security key-manager onboard update-passphrase` instead.

Related references

security key-manager external show on page 519
The `security key-manager update-passphrase` command provides a way to update the cluster-wide passphrase, created initially by running the `security key-manager setup` command, that is used for onboard key management. This command prompts for the existing passphrase, and if that passphrase is correct then the command prompts for a new passphrase.

When the `security key-manager update-passphrase` command is executed in a MetroCluster configuration, then run the `security key-manager setup` command with the new passphrase on the partner site before proceeding with any key-manager operations. This allows the updated passphrase to be replicated to the partner site.

### Examples

The following example updates the cluster-wide passphrase used for onboard key management:

```bash
cluster-1::*> security key-manager update-passphrase
Warning: This command will reconfigure the cluster passphrase for onboard key-management.
Do you want to continue? {y|n}: y
Enter current passphrase:
Enter new passphrase:
Reenter the new passphrase:
Update passphrase has completed. Save the new encrypted configuration data in a safe location so that you can use it if you need to perform a manual recovery operation. To view the data, use the "security key-manager backup show" command.
```

### security key-manager backup commands

The backup directory

#### security key-manager backup show

(DEPRECATED)-Show salt and wrapped keys as a hex dump

**Availability:** This command is available to cluster administrators at the `admin` privilege level.

**Description**

**Note:** This command is deprecated and might be removed in a future release. Use `security key-manager onboard show-backup` instead.

This command displays the backup information for onboard key management, which would be used to recover the cluster in case of catastrophic situations. The information displayed is for the cluster as a whole (not individual nodes). This command is not supported for an external key management configuration.

### Examples

The following example displays the onboard key management backup data for the cluster:

```bash
cluster-1::> security key-manager backup show
```

```bash
--------------------------BEGIN BACKUP--------------------------
```

```
TmV0QXBwTE1eSBCb09IAAEAAAAAAcAEAAAAAAADu+b+yAAAAACEAAAAAAAIAAAAAIAAAAACAAAACgAAAAAAAgAZJEIWvdeHr5RCAvHGclo+wAAAAAA
```

```bash
```
```
Commands: Manual Page Reference
security key-manager config commands

Modify key management configuration options

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
This command modifies the key management configuration options.

Parameters
[-cc-mode-enabled (true|false)] - Enable Common Criteria Mode

This parameter modifies the configuration state of the Onboard Key Manager (OKM) Common Criteria (CC) mode. CC mode enforces some of the policies required by the Common Criteria "Collaborative Protection Profile for Full Drive Encryption-Authorization Acquisition" (FDE-AA cPP) and "Collaborative Protection Profile for Full Drive Encryption-Encryption Engine" documents.

Examples
The following command enables Common Criterial mode in the cluster:

```
cluster-1::*> security key-manager config modify -cc-mode-enabled true
```
security key-manager config show

Display key management configuration options

Availability: This command is available to cluster administrators at the advanced privilege level.

Description

This command displays the key management configuration options.

The "cc-mode-enabled" option reflects the current configuraton state for Common-Criteria (CC) mode for onboard key management. CC mode is an operational mode that enforces some of the policies required by the Common Criteria "Collaborative Protection Profile for Full Drive Encryption-Authorization Acquisition" (FDE-AA cPP) and "Collaborative Protection Profile for Full Drive Encryption-Encryption Engine" documents. The feature can be enabled when the onboard key manager is configured using the security key-manager setup command or after the onboard key manager is configured using the security key-manager config modify command.

Examples

The following example displays the state of all key-manager configuration options:

```
cluster-1::*> security key-manager config show
CC-Mode
Enabled
--------
true
```

security key-manager external commands

Manage Configured External Key Managers

security key-manager external add-servers

Add External Key Management Servers

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description

This command adds the key management servers of the given hosts and ports to the given Vserver's external key manager's list of four possible key management servers. This command is not supported when external key management is not enabled for the given Vserver.

Parameters

-vserver <vserver name> - Vserver Name

Use this parameter to specify the Vserver on which to add the key management servers.

-key-servers <Hostname and Port>, ... - External Key Management Servers

Use this parameter to specify the list of additional key management servers that the external key manager uses to store keys.
Examples
The following example adds two key management servers to the list of servers used by the external key manager for Vserver cluster-1. The first key management server's hostname is keyserver1.local and is listening on the default port 5696, and the second key management server's IP is 10.0.0.20 and is listening on port 15696:

```bash
cluster-1::> security key-manager external add-servers -vserver cluster-1 -key-servers keyserver1.local, 10.0.0.20:15696
```

security key-manager external disable
Disable External Key Management

Availability: This command is available to cluster and Vserver administrators at the advanced privilege level.

Description
This command disables the external key manager associated with the given Vserver. If the key manager is in use by Data ONTAP, you cannot disable it. This command is not supported when onboard key management is enabled for the given Vserver.

Parameters
-vserver <vserver name> - Vserver Name
Use this parameter to specify the Vserver on which the external key manager is to be disabled.

Examples
The following example removes the external key manager for Vserver cluster-1:

```bash
cluster-1::*> security key-manager external disable -vserver cluster-1
Warning: This command will permanently delete the external key management configuration for Vserver "cluster-1".
Do you want to continue? {y|n}: y
```

security key-manager external enable
Enable External Key Management

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
This command enables the external key manager associated with the given Vserver. This command is not supported when a key manager for the given Vserver is already enabled.

Parameters
-vserver <vserver name> - Vserver Name
Use this parameter to specify the Vserver on which the external key manager is to be enabled.

-key-servers <Hostname and Port>, ... - List of External Key Management Servers
Use this parameter to specify the list of up to four key management servers that the external key manager uses to store keys.
- `client-cert <text>` - Name of the Client Certificate
  Use this parameter to specify the unique name of the client certificate that the key management servers use to ensure the identity of Data ONTAP.

- `server-ca-certs <text>, ...` - Names of the Server CA Certificates
  Use this parameter to specify the unique names of server-ca certificates that Data ONTAP uses to ensure the identity of the key management servers.

**Examples**

The following example enables the external key manager for Vserver cluster-1. The command includes three key management servers. The first key server's hostname is ks1.local and is listening on port 15696. The second key server's IP address is 10.0.0.10 and is listening on the default port 5696. The third key server's IPv6 address is fd20:8b1e:b255:814e:32bd:f35c:832c:5a09, and is listening on port 1234.

```
cluster-1::> security key-manager external enable -vserver cluster-1 -key-servers ks1.local:15696,10.0.0.10,[fd20:8b1e:b255:814e:32bd:f35c:832c:5a09]:1234 -client-cert AdminVserverClientCert -server-ca-certs ServerCaCert1,ServerCaCert2
```

**security key-manager external modify**

Modify External Key Management

**Availability:** This command is available to `cluster` and `Vserver` administrators at the `admin` privilege level.

**Description**

This command modifies the external key manager configuration associated with the given Vserver. This command is not supported when external key management is not enabled for the given Vserver.

**Parameters**

- `-vserver <vserver name>` - Vserver Name
  Use this parameter to specify the Vserver on which the key manager to be modified is located.

  - `-client-cert <text>` - Name of the Client Certificate
    Use this parameter to modify the name of the client certificate that the key management servers use to ensure the identity of Data ONTAP. If the keys of the new certificate do not match the keys of the existing certificate, or if the TLS connectivity with key-management servers fails with the new certificate, the operation fails. Running this command in the diagnostic privilege mode ignores failures and allows the command to complete.

  - `-server-ca-certs <text>, ...` - Names of the Server CA Certificates
    Use this parameter to modify the names of server-ca certificates that Data ONTAP uses to ensure the identity of the key management servers. Note that the list provided completely replaces the existing list of certificates. If the TLS connectivity with key-management servers fails with the new list of server-ca certificates, the operation fails. Running this command in the diagnostic privilege mode ignores failures and allows the command to complete.

**Examples**

The following example updates the client certificate used with the key management servers:

```
cluster-1::> security key-manager external modify -vserver cluster-1 -client-cert NewClientCert
```
security key-manager external modify-server

Modify Key Server Properties

Availability: This command is available to cluster and Vserver administrators at the advanced privilege level.

Description
This command modifies configuration information for configured key management servers. This command is supported only when external key manager has been enabled for the given Vserver.

Parameters
- `vserver <vserver name>` - Vserver Name
  Use this parameter to specify the Vserver on which to modify the key management server configuration.
- `key-server <Hostname and Port>` - External Key Server
  Use this parameter to specify the key management server for which the command modifies the configuration.
- `[timeout <integer>]` - Key Server I/O Timeout
  Use this parameter to specify the I/O timeout, in seconds, for the selected key management server.
- `[username <text>]` - Authentication User Name
  Use this parameter to specify the username with which Data ONTAP authenticates with the key management server.

Examples
The following example modifies the I/O timeout to 45 seconds for Vserver cluster-1, key server keyserver1.local:

```
  cluster-1::*> security key-manager modify-server -vserver cluster-1 -key-server keyserver1.local -timeout 45
```

The following example modifies the username and passphrase used to authenticate with key server keyserver1.local:

```
  cluster-1::*> security key-manager modify-server -vserver cluster-1 -key-server keyserver1.local -username ksuser
  Enter the password:
  Reenter the password:
```

security key-manager external remove-servers

Remove External Key Management Servers

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
This command removes the key management servers at the given hosts and ports from the given Vserver's external key manager's list of key management servers. If any of the specified key management servers is the sole storage location for any key that is in use by Data ONTAP, then you are unable to remove the key server. This command is not supported when external key management is not enabled for the given Vserver.

Parameters
- `vserver <vserver name>` - Vserver Name
  Use this parameter to specify the Vserver on which the external key manager is to be removed.
-key-servers <Hostname and Port>, ... - External Key Management Servers

Use this parameter to specify the list of key management servers that you want to remove from the external key manager.

Examples
The following example removes the key management server keyserver1.local, listening on the default port of 5696 and the key management server at IP 10.0.0.20, listening on port of 15696.

cluster-1::*> security key-manager external remove-servers -vserver cluster-1
-key-servers keyserver1.local,10.0.0.20:15696

security key-manager external restore

Restore the key ID pairs from the key management servers.

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
This command retrieves and restores any current unrestored keys associated with the storage controller from the specified key management servers. This command is not supported when external key management has not been enabled for the Vserver.

Parameters
[
-fields <fieldname>, ...]
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

[-instance ]
If you specify the -instance parameter, the command displays detailed information about all fields.

[-node <nodename> | local] - Node
This parameter specifies the name of the node that will load unrestored key IDs into its internal key table. If not specified, all nodes retrieve unrestored keys into their internal key table.

[-vserver <vserver name>] - Vserver Name
This parameter specifies the Vserver for which to list the keys. If not specified, this command restores key for all Vservers.

[-key-server <Hostname and Port>] - Key Server
If this parameter is specified, this command restores keys from the key management server identified by the host and port. If not specified, this command restores keys from all available key management servers.

[-key-id <Hex String>] - Key ID
If you specify this parameter, then the command restores only the key IDs that match the specified value.

[-key-tag <text>] - Key Tag
If you specify this parameter, then the command restores only the key IDs that match the specified key-tag. The key-tag for Volume Encryption Keys (VEKs) is set to the UUID of the encrypted volume. If not specified, all key ID pairs for any key tags are restored.

Examples
The following command restores keys that are currently on a key server but are not stored within the key tables on the cluster. One key is missing for vserver clus- ter-1 on node1, and another key is missing for vserver datavs on node1 and node2:
security key-manager external show

Show the set of configured external key management servers

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
This command displays the external key management servers configured on the cluster for a given Vserver. No entries are displayed when external key management is not enabled for the given Vserver.

Parameters

{-fields <fieldname>, ...}  
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

{-instance}}  
If you specify the -instance parameter, the command displays detailed information about all fields.

-[<vserver name>] - Vserver Name

If you specify this parameter, then the command displays the key management servers for only the given Vserver.

-[<key-server <text>] - Key Server Name with port

If you specify this parameter, then the command displays only the given key management server with the given host name or IP address listening on the given port.

-[<client-cert <text>]] - Name of the Client Certificate

If you specify this parameter, then the command displays only the key management servers using a client certificate with the given name.

-[<server-ca-certs <text>, ...] - Names of the Server CA Certificates

If you specify this parameter, then the command displays only the key management servers using server-ca certificates with the given names.
[\texttt{-timeout <integer>}] - Server I/O Timeout

If you specify this parameter, then the command displays only the key management servers using the given I/O timeout.

[\texttt{-username <text>}] - Authentication User Name

If you specify this parameter, then the command displays only the key management servers using the given authentication username.

### Examples

The following example lists all configured key management servers for all Vservers:

```
cluster-1::> security key-manager external show

Vserver: datavs
    Client Certificate: datavsClientCert
    Server CA Certificates: datavsServerCaCert1, datavsServerCaCert2

Key Server
--------------------------------------------
keyserver.datavs.com:5696

Vserver: datavs
    Client Certificate: AdminClientCert
    Server CA Certificates: AdminServerCaCert

Key Server
--------------------------------------------
10.0.0.10:1234
fd20:8b1e:b255:814e:32bd:f35c:832c:5a09:1234
ks1.local:1234
4 entries were displayed.
```

The following example lists all configured key management servers with more detail, including timeouts and usernames:

```
cluster-1::> security key-manager external show -instance

Vserver: datavs
    Client Certificate: datavsClientCert
    Server CA Certificates: datavsServerCaCert1, datavsServerCaCert2
    Key Server: keyserver.datavs.com:5696
    Timeout: 25
    Username: datavsuser

Vserver: cluster-1
    Client Certificate: AdminClientCert
    Server CA Certificates: AdminServerCaCert
    Key Server: 10.0.0.10:1234
    Timeout: 25
    Username:

Vserver: cluster-1
    Client Certificate: AdminClientCert
    Server CA Certificates: AdminServerCaCert
    Key Server: fd20:8b1e:b255:814e:32bd:f35c:832c:5a09:1234
    Timeout: 25
    Username:

Vserver: cluster-1
    Client Certificate: AdminClientCert
    Server CA Certificates: AdminServerCaCert
    Key Server: ks1.local:1234
    Timeout: 45
```
security key-manager external show-status

Show the set of configured external key management servers

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

**Description**
This command displays connectivity information between Data ONTAP nodes and configured external key management servers.

**Parameters**

\[
\text{[-fields <fieldname>, ...]}
\]

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

\[
\text{[-instance ]}
\]

If you specify the `-instance` parameter, the command displays detailed information about all fields.

\[
\text{[-node <nodename>|local] - Node Name}
\]

If you specify this parameter, then the command displays the connectivity information for only the given node.

\[
\text{[-vserver <vservername>] - Vserver Name}
\]

If you specify this parameter, then the command displays the key management servers for only the given Vserver.

\[
\text{[-key-server <Hostname and Port>] - Key Server}
\]

If you specify this parameter, then the command displays the connectivity information for only the given key management server with the given name listening on the given port.

\[
\text{[-key-server-status {available|not-responding|unknown}] - Key Server Status}
\]

If you specify this parameter, then the command displays the connectivity information for only the key management servers with the given status.

**Examples**
The following example lists all configured key management servers for all Vservers:

```
cluster-1::> security key-manager external show-status

<table>
<thead>
<tr>
<th>Node</th>
<th>Vserver</th>
<th>Key Server</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>node1</td>
<td>datavs</td>
<td>keyserver.datavs.com:5696</td>
<td>available</td>
</tr>
<tr>
<td></td>
<td></td>
<td>10.0.0.10:5696</td>
<td>available</td>
</tr>
<tr>
<td></td>
<td></td>
<td>fd20:8b1e:b255:814e:32bd:f35c:832c:5a09:1234</td>
<td>available</td>
</tr>
<tr>
<td></td>
<td></td>
<td>ksl1.local:15696</td>
<td>available</td>
</tr>
<tr>
<td>node2</td>
<td>datavs</td>
<td>keyserver.datavs.com:5696</td>
<td>available</td>
</tr>
<tr>
<td></td>
<td></td>
<td>10.0.0.10:5696</td>
<td>available</td>
</tr>
<tr>
<td></td>
<td></td>
<td>fd20:8b1e:b255:814e:32bd:f35c:832c:5a09:1234</td>
<td>available</td>
</tr>
</tbody>
</table>
```

security key-manager commands  521
security key-manager external boot-interfaces commands

The boot-interfaces directory

security key-manager external boot-interfaces modify

Modify external key manager logical interfaces

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
This command enables cluster administrators to modify the IP address and route information that the external key manager uses at boot time to restore keys from external key servers.

Parameters
- node {<nodename>|local} - Node
  Use this parameter to modify information on the node that you specify.
- address-type {ipv4|ipv6|ipv6z} - Address Type
  Use this parameter to modify information for the address-type that you specify.
- [address <IP Address>] - Local Interface Address
  Use this parameter to modify the IP address that the system will use at boot time to restore keys from external key servers. This parameter implies -override-default true.
{ [netmask <IP Address>] - Network Mask
  Use this parameter to modify the IP netmask that the system will use at boot time to restore keys from external key servers. This parameter can be used only with address-type ipv4. This parameter implies -override-default true.
[netmask-length <integer>] - Bits in Network Mask
  Use this parameter to modify the IP netmask length that the system will use at boot time to restore keys from external key servers. This parameter implies -override-default true.
- [gateway <IP Address>] - Gateway
  Use this parameter to modify the IP gateway that the system will use at boot time to restore keys from external key servers. This parameter implies -override-default true.
- [port {<netport>|<ifgrp>}] - Network Port
  Use this parameter to modify the port that the system will use at boot time to restore keys from external key servers. The value that you specify cannot be a vlan or ifgrp port. This parameter implies -override-default true.
[-override-default {true|false}] - Override Default Setting?
  Use this parameter to modify the system's selection of boot time IP address and route information. When this value is false, the system will use the information associated with a node management LIF. When this value is true, then the administrator has chosen to override the defaults.

Examples
The following shows how to modify the port used by node "node2" at boot time to restore keys from external IPv4 key servers. In the example, IPv6 is not enabled in the cluster, so the -address-type parameter defaults to ipv4.
The following example shows how to modify the IP address and gateway parameters used by node "node1" at boot time to restore keys from external IPv6 key servers.

```
cluster-1::*> security key-manager external boot-interfaces modify -node node1 -address-type ipv6 -
address fd20:8b1e:b255:814e:749e:11a3:3bff:5820 -gateway fd20:8b1e:b255:814e::1
```

### security key-manager external boot-interfaces show

Show external key manager logical interfaces

**Availability:** This command is available to cluster administrators at the *advanced* privilege level.

**Description**

This command enables cluster administrators to view the IP address and route information that the external key manager uses at boot time to restore keys from external key servers.

**Parameters**

{-fields <fieldname>, ...}

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

`[-instance]`

If you specify the `-instance` parameter, the command displays detailed information about all fields.

`[-node {<nodename>|local}]` - Node

Use this parameter to display information only about boot-time IP address and route information for the node that you specify.

`[-address-type {ipv4|ipv6|ipv6z}]` - Address Type

Use this parameter to display information only about boot-time IP address and route information for the address-type that you specify.

`[-address <IP Address>]` - Local Interface Address

Use this parameter to display information only about boot-time IP address and route information for the IP address that you specify.

`[-netmask <IP Address>]` - Network Mask

Use this parameter to display information only about boot-time IP address and route information for the network mask that you specify.

`[-netmask-length <integer>]` - Bits in Network Mask

Use this parameter to display information only about boot-time IP address and route information for the network mask length that you specify.

`[-gateway <IP Address>]` - Gateway

Use this parameter to display information only about boot-time IP address and route information for the gateway that you specify.

`[-port {<netport>|<ifgrp>}]` - Network Port

Use this parameter to display information only about boot-time IP address and route information for the port that you specify.
Override Default Setting?

Use this parameter to display information only about boot-time IP address and route information with the override-default setting that you specify.

Examples

The following example shows how to display the IP address and route information that the external key manager uses at boot time to restore keys. In the example, IPv6 is not enabled in the cluster and, as a result, the command displays information for only the IPv4 address-type. The override-default value is false for all rows, which indicates that the system automatically configured the values based on the node management LIF configuration on the nodes.

```
cluster-1::*> security key-manager external boot-interfaces show
          Node     Type    Address/Mask       Gateway         Port  Default?
          -------- ------- ------------------ --------------- ----- --------
node1    ipv4    10.224.113.159/24  10.224.113.1    e0M   false
node2    ipv4    10.224.113.160/24  10.224.113.1    e0M   false
2 entries were displayed.
```

The following example shows how to display the IP address and route information that the external key manager uses at boot time to restore keys. In the example, IPv6 is enabled in the cluster and, as a result, the command displays information for both the IPv4 and IPv6 address-types. The override-default value is false for most rows, which indicates that the system automatically configured the values based on the node management LIF configuration on the nodes. The override-default value for node1 and address-type ipv4 is true, which indicates an administrator has used the `security key-manager external boot-interfaces modify` command to override one or more fields, and that the values may differ from the corresponding node management LIF.

```
cluster-1::*> security key-manager external boot-interfaces show
          Node     Type    Address/Mask       Gateway         Port  Default?
          -------- ------- ------------------ --------------- ----- --------
node1    ipv4    10.224.113.159/24  10.224.113.1    e0d   true
          ipv6    fd20:8b1e:b255:814e:32bd:f35c:832c:5a09/64
                   fd20:8b1e:b255:814e::1
                   e0M   false
node2    ipv4    10.224.113.160/24  10.224.113.1    e0M   false
          ipv6    fd20:8b1e:b255:814e:749e:11a3:3bff:5820/64
                   fd20:8b1e:b255:814e::1
                   e0M   false
4 entries were displayed.
```

security key-manager key commands

The key directory

security key-manager key create

Create a new authentication key

Availability: This command is available to `cluster` administrators at the `admin` privilege level.
Description
This command creates a new authentication key (AK) and stores it on the the admin Vserver's key management servers. The command fails if the configured key management servers are already storing more than 256 AKs. If this command fails because there are more than 256 AKs in the cluster, delete unused keys on the Vserver's key management servers and retry the command. This command is not supported when external key management is not enabled for the admin Vserver.

Parameters

[-key-tag <text>] - Key Tag
This parameter specifies the key tag to associate with the new authentication key (AK). The default value is the node name. This parameter can be used to help identify created authentication keys (AKs). For example, the `security key-manager key query` command's key-tag parameter can be used to query for a specific key-tag value.

[-prompt-for-key {true|false}] - Prompt for Authentication Passphrase
If you specify this parameter as true, then the command prompts you to enter an authentication passphrase manually instead of generating it automatically. For security reasons, the authentication passphrase you entered is not displayed at the command prompt. You must enter the authentication passphrase a second time for verification. To avoid errors, copy and paste authentication passphrases electronically instead of entering them manually. Data ONTAP saves the resulting authentication key/key ID pair automatically on the configured key management servers.

Examples

The following example creates an authentication key with the node name as the default key-tag value:

```
cluster-1::> security key-manager key create
Key ID: 00000000000000000200000000000100d0f7c2462626b739fe81b89f29a092f0000000000000000
```

The following example creates an authentication key with a user-specified authentication passphrase:

```
cluster-1::> security key-manager key create -prompt-for-key true
Enter a new passphrase:
Reenter the passphrase:
Key ID: 000000000000000002000000000001006268333f870860128f9be17d393e5083b0000000000000000
```

Related references

- `security key-manager key query` on page 526

security key-manager key delete
Delete an existing authentication key

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
This command removes an authentication key from the configured key management servers on the admin Vserver. The command fails if the given key is currently in use by Data ONTAP. This command is not supported when external key management is not enabled for the admin Vserver.

Parameters

- `-key-id <Hex String>` - Authentication Key ID
  Use this parameter to specify the key ID of the key that you want to remove.
Examples
The following example deletes an authentication key:

```
cluster-1::*> security key-manager key delete -key-id
000000000000000002000000000000001006268333f870860128fbe17d393e5083b0000000000000000
```

security key-manager key migrate
Migrate keys from the admin Vserver's onboard key manager to a data Vserver's external key manager and vice versa

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *advanced* privilege level.

**Description**
This command provides a mechanism to migrate the existing keys of a data Vserver from the admin Vserver's key manager to their own key manager or vice versa. The keys stay the same and the data is not rekeyed, only the keys are migrated from one Vserver's key manager to another. After a successful migration to the new key manager, the data Vserver keys are deleted from the previous key manager.

**Note:** This command currently only supports key migration from the Admin Vserver's onboard key manager to a Data Vserver's external key manager and vice versa.

**Parameters**
- `--from-vserver <vserver name>` - Vserver Name
  Use this parameter to specify the name of the Vserver whose key manager the keys are migrated from.
- `--to-vserver <vserver name>` - Vserver Name
  Use this parameter to specify the name of the Vserver whose key manager the keys are migrated to.

**Examples**
The following example migrates the keys of "datavs" data Vserver from "cluster-1" admin Vserver's key manager to "datavs" data Vserver's key manager:

```
cluster-1::> security key-manager key migrate --from-vserver cluster-1 --to-vserver datavs
```

The following example migrates the keys of "datavs" data Vserver from "datavs" data Vserver's key manager to "cluster-1" admin Vserver's key manager:

```
cluster-1::> security key-manager key migrate --from-vserver datavs --to-vserver cluster-1
```

security key-manager key query
Displays the key IDs stored in a key management server.

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

**Description**
This command displays the IDs of the keys that are stored in the configured key managers. This command does not update the key tables on the node.
Parameters
{%fields <fieldname>,...%}
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

[[-instance]]
If you specify the -instance parameter, the command displays detailed information about all fields.

[-node {<nodename>|local}] - Node
Use this parameter to specify the name of the node that queries the specified key management servers. If this parameter is not specified, then all nodes query the specified key management servers.

[-vserver <vserver name>] - Vserver Name
Use this parameter to specify the Vserver for which to list the keys.

[-key-server <Hostname and Port>] - Key Server
This parameter specifies the host and port of the key management server that you want to query. This parameter is used only with external key managers.

[-key-id <Hex String>] - Key Identifier
If you specify this parameter, then the command displays only the key IDs that match the specified value.

[-key-tag <text>] - Key Tag
If you specify this parameter, then the command displays only the key IDs that match the specified value. The key-tag for Volume Encryption Keys (VEKs) is set to the UUID of the encrypted volume.

[-key-type <Key Usage Type>] - Key Type
If you specify this parameter, then the command displays only the key IDs that match the specified value.

[-restored {true|false}] - Restored
This parameter specifies whether the key corresponding to the displayed key ID is present in the specified node's internal key table. If you specify 'yes' for this parameter, then the command displays the key IDs of only those keys that are present in the system's internal key table. If you specify 'no' for this parameter, then the command displays the key IDs of only those keys that are not present in the system's internal key table.

[-key-store <Key Store>] - Key Store
Use this parameter to specify the key manager type from which to list the keys.

[-key-user <vserver name>] - Key User
If you specify this parameter, then the command displays only the key IDs that are used by the specified Vserver.

Examples
The following example shows all of the keys on all configured key servers, and whether or not those keys have been restored for all nodes in the cluster:

```
cluster-1::> security key-manager key query

Vserver: cluster-1
Key Manager: onboard
Node: node1
Key Server: ""

Key Tag Key Type Restored
--------- -------- --------
node1 NSE-AK yes
Key ID: 000000000000000002000000000001000c11b3863f78c2273343d7ec5a67762e0000000000000000
node1 NSE-AK yes
Key ID: 000000000000000002000000000001006f4e2513353a674305872a4c9f3bf7970000000000000000
node1 NSE-AK yes
Key ID: 00000000000000000200000000000100e1f6b27094485d2d74408bca673b25eb0000000000000000
```
### security key-manager key show

(DEPRECATED)-Display encryption key IDs stored in onboard key manager

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**

**Note:** This command is deprecated and might be removed in a future release. Use *security key-manager key query* instead.

This command displays the key IDs of the authentication keys (NSE-AK) and SVM keys (SVM-KEK) that are available in onboard key management. This command is not supported for an external key management configuration.

**Parameters**

```
[-fields <fieldname>, ...]
```

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `?-fields ?` to display the fields to specify.

---

**Key Tag** | **Key Type** | **Restored**

---
If this parameter is specified, the command displays additional details about the key IDs.

If you specify the \texttt{-instance} parameter, the command displays detailed information about all fields.

\texttt{-node} \texttt{<nodename>|local}} - Node

If this parameter is specified, the command displays information only about key IDs that are located on the specified storage system.

\texttt{-key-store} \texttt{<Key Store>} - Key Store

If this parameter is specified, the command displays information only about key IDs that are managed by the specified key management. For example, use \texttt{onboard} for onboard key management.

\texttt{-key-id} \texttt{<text>} - Key Identifier

If this parameter is specified, the command displays information only about the specified key IDs.

\texttt{-key-tag} \texttt{<text>} - Key Tag

If this parameter is specified, the command displays information only about key IDs that have the specified key tags.

\texttt{-key-location} \texttt{<text>} - Key Location

If this parameter is specified, the command displays information only about key IDs that are located on the specified key location. For example, use \texttt{local-cluster} for onboard key management.

\texttt{-used-by} \texttt{<Key Usage Type>} - Used By

If this parameter is specified, the command displays information only about key IDs that are associated with the specified application usage of the keys. For example, "NSE-AK" would display key IDs only for NSE drives.

\texttt{-restored} \texttt{yes|no} - Restored

If this parameter is specified, the command displays information only about key IDs that have the specified value of restored keys. If restored is \texttt{yes}, then the corresponding key is available (normal). If restored is \texttt{no}, use the \texttt{security key-manager setup} command to restore the key. See the man page for \texttt{security key-manager setup} for details.

\textbf{Examples}

The following example shows all keys stored in the onboard key manager:

```
cluster-1::> security key-manager key show

Node: node1
Key Store: onboard
Used By
--------
NSE-AK
Key ID: 000000000000000002000000000001001bc4c708e2a89a312e14b6ce6d4d9d490000000000000000
NSE-AK
Key ID: 000000000000000002000000000001005e89099721f8817e65e3eb68be1bfca0000000000000000
SVM-KEK
Key ID: 00000000000000000200000000000a0046df92864d4c6e6eb2fca0000000000000000

Node: node2
Key Store: onboard
Used By
--------
NSE-AK
Key ID: 000000000000000002000000000001001bc4c708e2a89a312e14b6ce6d4d9d490000000000000000
NSE-AK
Key ID: 000000000000000002000000000001005e89099721f8817e65e3eb68be1bfca0000000000000000
```
The following example shows a detailed view of all keys stored in the onboard key manager:

```
cluster-1::> security key-manager key show -detail
```

security key-manager onboard commands

Manage Onboard Key Managers

security key-manager onboard disable

Disable onboard key management

**Availability:** This command is available to `cluster` administrators at the `advanced` privilege level.

**Description**

This command disables the onboard key manager associated with the admin Vserver and permanently deletes the onboard key management configuration associated with the admin Vserver.

**Examples**

The following example disables the onboard key manager for the admin Vserver:

```
cluster-1::*> security key-manager onboard disable
```

Warning: This command will permanently delete all keys from onboard key management.

Do you want to continue? {y|n}: y
security key-manager onboard enable

Enable onboard key manager

Availability: This command is available to cluster administrators at the admin privilege level.

Description

This command enables the onboard key manager for the admin Vserver.

Parameters

\[-cc-mode-enabled \{yes|no\}\] - Enable Common Criteria Mode?

Use this parameter to specify whether the Common Criteria (CC) mode should be enabled or not. When CC mode is enabled, you are required to provide a cluster passphrase that is between 64 and 256 ASCII character long, and you are required to enter that passphrase each time a node reboots. CC mode cannot be enabled in a MetroCluster configuration.

Examples

The following example enables the Onboard Key Manager for the admin Vserver cluster-1:

```
cluster-1::> security key-manager onboard enable
Enter the cluster-wide passphrase for onboard key management:
Re-enter the cluster-wide passphrase:
After configuring onboard key management, save the encrypted configuration data in a safe location so that you can use it if you need to perform a manual recovery operation. To view the data, use the "security key-manager onboard show-backup" command.
```

security key-manager onboard show-backup

Show salt and wrapped keys for the admin Vserver as a hex dump

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description

This command displays the backup information for onboard key management for the admin Vserver, which can be used to recover the cluster in case of catastrophic situations. The information displayed is for the cluster as a whole (not individual nodes).

Parameters

\[-fields <fieldname>,...\]

If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

\[-instance\]

If you specify the -instance parameter, the command displays detailed information about all fields.

Examples

The following example displays the onboard key management backup data for the admin Vserver:

```
cluster-1::> security key-manager onboard show-backup
--------------------------BEGIN BACKUP--------------------------
TmV0QXBwIEtleSBCbG9iAAEAAAAEAAAAcAEAAAAAADuD+byAAAAACEAAAAAAA
```
security key-manager onboard sync

Sync onboard key management keys

Availability: This command is available to cluster administrators at the admin privilege level.

Description
This command synchronizes missing onboard keys on any node in the cluster. For example, if you add a node to a cluster that has onboard key management configured, you should then run this command to synchronize the keys. In a MetroCluster configuration, if the security key-manager onboard enable command is used to enable onboard key management on one site, then run the security key-manager onboard sync command on the partner site. In a MetroCluster configuration, if the security key-manager onboard update-passphrase command is used to update the passphrase on one site, then run this command with the new passphrase on the partner site before proceeding with any key management operations.

Examples
The following example synchronizes the onboard key manager key database across all nodes in the cluster. In a MetroCluster configuration, this command synchronizes nodes in the local site.

```
class-1::> security key-manager onboard sync
```

Related references
security key-manager onboard enable on page 531
security key-manager onboard update-passphrase on page 533
security key-manager onboard update-passphrase

Update the Onboard Key Management Passphrase

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
This command provides a way to update the cluster-wide passphrase that is used for onboard key management and initially created by running the security key-manager onboard enable command. This command prompts for the existing passphrase, and if that passphrase is correct then the command prompts for a new passphrase. When onboard key management is enabled for the admin Vserver, run the security key-manager onboard show-backup command after updating the passphrase and save the output for emergency recovery scenarios. When the security key-manager onboard update-passphrase command is executed in a MetroCluster configuration, then run the security key-manager onboard sync command with the new passphrase on the partner site before proceeding with any key-manager operations. This allows the updated passphrase to be replicated to the partner site.

Examples
The following example updates the cluster-wide passphrase used for onboard key management:

cluster-1::* security key-manager onboard update-passphrase
Warning: This command will reconfigure the cluster passphrase for onboard key management.
Do you want to continue? {y|n}: y
Enter current passphrase:
Enter new passphrase:
Reenter the new passphrase:
Update passphrase has completed. Save the new encrypted configuration data in a safe location so that you can use it if you need to perform a manual recovery operation. To view the data, use the "security key-manager onboard show-backup" command.

security login commands
Manage login methods, roles, and passwords

security login create
Add a login method

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The security login create command creates a login method for the management utility. A login method consists of a user name, an application (access method), and an authentication method. A user name can be associated with multiple applications. It can optionally include an access-control role name. If an Active Directory, LDAP, or NIS group name is used, then the login
method gives access to users belonging to the specified group. If the user is a member of multiple groups provisioned in the security login table, then the user will get access to a combined list of the commands authorized for the individual groups.

**Parameters**

- `-vserver <Vserver Name>` - Vserver
  
  This specifies the Vserver name of the login method.

- `-user-or-group-name <text>` - User Name or Group Name
  
  This specifies the user name or Active Directory, LDAP, or NIS group name of the login method. The Active Directory, LDAP, or NIS group name can be specified only with the `domain` or `nsswitch` authentication method and `ontapi` and `ssh` application. If the user is a member of multiple groups provisioned in the security login table, then the user will get access to a combined list of the commands authorized for the individual groups.

- `-application <text>` - Application
  
  This specifies the application of the login method. Possible values include console, http, ontapi, rsh, snmp, service-processor, ssh, and telnet.

  Setting this parameter to `service-processor` grants the user access to the Service Processor (SP). Because the SP supports only password authentication, when you set this parameter to `service-processor`, you must also set the `-authentication-method` parameter to `password`. Vserver user accounts cannot access the SP. Therefore, you cannot use the `-vserver` parameter when you set this parameter to `service-processor`.

- `-authentication-method <text>` - Authentication Method
  
  This specifies the authentication method for login. Possible values include the following:

  - `cert` - SSL certificate authentication
  - `community` - SNMP community strings
  - `domain` - Active Directory authentication
  - `nsswitch` - LDAP or NIS authentication
  - `password` - Password
  - `publickey` - Public-key authentication
  - `usm` - SNMP user security model
  - `saml` - SAML authentication

- `[-remote-switch-ipaddress <IP Address>]` - Remote Switch IP Address
  
  This specifies the IP address of the remote switch. The remote switch could be a cluster switch monitored by cluster switch health monitor (CSHM) or a Fibre Channel (FC) switch monitored by MetroCluster health monitor (MCC-HM). This parameter is applicable only when the application is `snmp` and authentication method is `usm` (SNMP user security model).

- `-role <text>` - Role Name
  
  This specifies an access-control role name for the login method.

- `[-comment <text>]` - Comment Text
  
  This specifies comment text for the user account, for example, "Guest account". The maximum length is 128 characters.

- `[-is-ns-switch-group (yes|no)]` - Whether Ns-switch Group
  
  This specifies whether `user-or-group-name` is an LDAP or NIS group. Possible values are yes or no. Default value is no.
-second-authentication-method (none|publickey|password|nsswitch) - Second Authentication Method

This specifies the authentication method for the login. It will be used as the second factor for authentication. Possible values include the following:

- password - Password
- publickey - Public-key authentication
- nsswitch - NIS or LDAP authentication
- none - default value

Examples

The following example illustrates how to create a login that has the user name `monitor`, the application `ssh`, the authentication method `password`, and the access-control role `guest` for Vserver `vs`:

```
cluster1::> security login create -vserver vs -user-or-group-name monitor
-appliication ssh -authentication-method password -role guest
```

The following example illustrates how to create a login that has the user name `monitor`, the application `ontapi`, the authentication method `password`, and the access-control role `vsadmin` for Vserver `vs`:

```
cluster1::> security login create -vserver vs -user-or-group-name monitor
-appliication ontapi -authentication-method password -role vsadmin
```

The following example illustrates how to create a login that has the user name `monitor`, the application `ssh`, the authentication method `publickey`, and the access-control role `guest` for Vserver `vs`:

```
cluster1::> security login create -vserver vs -user-or-group-name monitor
-appliication ssh -authentication-method publickey -role guest
```

The following example illustrates how to create a login that has the user name `monitor`, the application `http`, the authentication method `cert`, and the access-control role `admin` for Vserver `vs`:

```
cluster1::> security login create -vserver vs -user-or-group-name monitor
-appliication http -authentication-method cert -role admin
```

The following example illustrates how to create a login that has the Active Directory group name `adgroup` in `DOMAIN1`, the application `ssh`, the authentication method `domain`, and the access-control role `vsadmin` for Vserver `vs`:

```
cluster1::> security login create -vserver vs
-user-or-group-name DOMAIN1\adgroup -application ssh
-authentication-method domain -role vsadmin
```

The following example illustrates how to create a login that has a group name `nssgroup` in the LDAP or NIS server, the application `ontapi`, the authentication method `nsswitch`, and the access-control role `vsadmin` for Vserver `vs`. Here `is-ns-switch-group` must be set to `yes`:

```
cluster1::> security login create -vserver vs -user-or-group-name nssgroup
-appliication ontapi -authentication-method nsswitch -role vsadmin
-is-ns-switch-group yes
```
The following example illustrates how to create a login that has the user name `monitor`, the application `ssh`, the authentication method `password`, the second authentication method `publickey` and the access-control role `vsadmin` for Vserver `vs`:

```
cluster1::> security login create -vserver vs -user-or-group-name monitor
        -application ssh -authentication-method password
        -second-authentication-method publickey -role vsadmin
```

The following example illustrates how to create a login that has the user name `monitor`, the application `ssh`, the authentication method `password`, the second authentication method `none` and the access-control role `vsadmin` for Vserver `vs`:

```
cluster1::> security login create -vserver vs -user-or-group-name monitor
        -application ssh -authentication-method password
        -second-authentication-method none -role vsadmin
```

**security login delete**

Delete a login method

**Availability:** This command is available to cluster administrators at the `admin` privilege level.

**Description**
The `security login delete` command deletes a login method.

**Parameters**

- `-vserver <Vserver Name>` - `Vserver`
  
  This optionally specifies the Vserver name of the login method.

- `-user-or-group-name <text>` - `User Name or Group Name`
  
  This specifies the user name or Active Directory, LDAP, or NIS group name of the login method that is to be deleted. A user name can be associated with multiple applications.

- `-application <text>` - `Application`
  
  This specifies the application of the login method. Possible values include console, http, ontapi, rsh, snmp, service-processor, ssh, and telnet.

- `-authentication-method <text>` - `Authentication Method`
  
  This specifies the authentication method of the login method. Possible values include the following:

  - `cert` - SSL certificate authentication
  - `community` - SNMP community strings
  - `domain` - Active Directory authentication
  - `nsswitch` - LDAP or NIS authentication
  - `password` - Password
  - `publickey` - Public-key authentication
  - `usm` - SNMP user security model
  - `saml` - SAML authentication
[-remote-switch-<ipaddress <IP Address>]] - Remote Switch IP Address

This specifies the IP address of the remote switch. The remote switch could be a cluster switch monitored by cluster switch health monitor (CSHM) or a fibre Channel (FC) switch monitored by MetroCluster health monitor (MCC-HM). This parameter is applicable only when the application is *snmp* and authentication method is *usm* (SNMP user security model).

### Examples

The following example illustrates how to delete a login that has the username *guest*, the application *ssh*, and the authentication method *password* for Vserver *vs*:

```bash
cluster1::> security login delete -user-or-group-name guest
   -application ssh -authentication-method password -vserver vs
```

The following example illustrates how to delete a login that has the username *guest*, the application *ontapi*, and the authentication method *cert* for Vserver *vs*:

```bash
cluster1::> security login delete -user-or-group-name guest
   -application ontapi -authentication-method cert -vserver vs
```

The following example illustrates how to delete a login that has the Active Directory group name *adgroup* in *DOMAIN1*, the application *ssh*, and the authentication method *domain* for Vserver *vs*:

```bash
cluster1::> security login delete -user-or-group-name DOMAIN1\adgroup
   -application ssh -authentication-method domain -vserver vs
```

The following example illustrates how to delete a login that has a group name *nssgroup* in the LDAP or NIS server, the application *ontapi*, and the authentication method *nsswitch* for Vserver *vs*:

```bash
cluster1::> security login delete -user-or-group-name nssgroup
   -application ontapi -authentication-method nsswitch -vserver vs
```

security login expire-password

Expire user's password

**Availability:** This command is available to cluster administrators at the *admin* privilege level.

**Description**
The *security login expire-password* command expires a specified user account password, forcing the user to change the password upon next login.

**Parameters**

- **-vserver <Vserver Name>** - Vserver
  This optionally specifies the Vserver to which the user account belongs.

- **-username <text>** - Username
  This specifies the user name of the account whose password you want to expire.

[-hash-function (sha512|sha256)] - Password Hash Function

This optionally specifies the password-hashing algorithm used for encrypting the passwords that you want to expire. The supported values include are as follows:
- sha512 - Secure hash algorithm (512 bits)
- sha256 - Secure hash algorithm (256 bits)
- md5 - Message digest algorithm (128 bits)

[\[\text{\texttt{lock-after <integer>}}\text{\texttt{\}}} - Lock User Account After N days (privilege: advanced)]

This optionally specifies the number of days after which the new password hash policy will be enforced. The enforcement will lock all user accounts that are still compliant with the provided hash algorithm using \texttt{-hash-function} parameter.

</tbody>
</table>

**security login lock**

Lock a user account with password authentication method

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**
The \texttt{security login lock} command locks a specified account, preventing it from accessing the management interface.

**Parameters**
- \texttt{-vserver \textit{<Vserver Name>}} - Vserver
  
  This optionally specifies the Vserver to which the user account belongs.

- \texttt{-username \textit{<text>}} - Username
  
  This specifies the user name of the account that is to be locked.

<table>
<thead>
<tr>
<th>Examples</th>
</tr>
</thead>
</table>
| The following example locks a user account named 'jdoe' which belongs to the Vserver 'vs1'.
security login modify

Modify a login method

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The security login modify command modifies the access-control role name of a login method. If the user is a member of multiple groups provisioned in the security login table, then the user will get access to a combined list of the commands authorized for the individual groups.

Parameters

-vserver <Vserver Name> - Vserver
This specifies the Vserver name of the login method.

-user-or-group-name <text> - User Name or Group Name
This specifies the user name, Active Directory, LDAP, or NIS group name of the login method that is to be modified. A user name can be associated with multiple applications. If the user is a member of multiple groups provisioned in the security login table, then the user will get access to a combined list of the commands authorized for the individual groups.

-application <text> - Application
This specifies the application of the login method. Possible values include console, http, ontapi, rsh, snmp, service-processor, ssh, and telnet.

-authentication-method <text> - Authentication Method
This specifies the authentication method of the login method. Possible values include the following:
- cert - SSL certificate authentication
- community - SNMP community strings
- domain - Active Directory authentication
- nsswitch - LDAP or NIS authentication
- password - Password
- publickey - Public-key authentication
- usm - SNMP user security model
- saml - SAML authentication

[-remote-switch-ipaddress <IP Address>] - Remote Switch IP Address
This specifies the IP address of the remote switch. The remote switch could be a cluster switch monitored by cluster switch health monitor (CSHM) or a Fibre Channel (FC) switch monitored by MetroCluster health monitor (MCC-HM). This parameter is applicable only when the application is snmp and authentication method is usm (SNMP user security model).

[-role <text>] - Role Name
This modifies the access-control role name for the login method.

[-comment <text>] - Comment Text
This specifies comment text for the user account, for example, "Guest account". The maximum length is 128 characters.
[-is-ns-switch-group \{yes\|no\}] - Whether Ns-switch Group

This specifies if user-or-group-name is an LDAP or NIS group. Possible values are yes or no. Default value is no.

[-second-authentication-method \{none\|publickey\|password\|nsswitch\}] - Second Authentication Method

This specifies the authentication method for the login method. It will be used as the second factor for authentication. Possible values include the following:

- password - Password
- publickey - Public-key authentication
- nsswitch - NIS or LDAP authentication
- none - default value

Examples

The following example illustrates how to modify a login method that has the user name guest, the application ontapi, and the authentication method password to use the access-control role guest for Vserver vs:

```
cluster1::> security login modify -user-or-group-name guest
-application ontapi -authentication-method password -role guest
-vserver vs
```

The following example illustrates how to modify a login method that has the user name guest, the application ssh, and the authentication method publickey to use the access-control role vsadmin for Vserver vs:

```
cluster1::> security login modify -user-or-group-name guest
-application ssh -authentication-method publickey -role vsadmin
-vserver vs
```

The following example illustrates how to modify a login method that has the group name nssgroup, the application ontapi, and the authentication method nsswitch to use the access-control role readonly for Vserver vs. Here is-ns-switch-group must be set to yes:

```
cluster1::> security login modify -user-or-group-name nssgroup
-application ontapi -authentication-method nsswitch -role readonly
-vserver vs -is-ns-switch-group yes
```

The following example illustrates how to modify a login method that has the user name guest, the application ssh, and the authentication method publickey to use the second-authentication-method password for Vserver vs:

```
cluster1::> security login modify -user-or-group-name guest
-application ssh -authentication-method publickey
-second-authentication-method password -vserver vs
```

The following example illustrates how to modify a login method to have individual authentication methods that have the user name guest, the application ssh, and the authentication method publickey to use the second-authentication-method none for Vserver vs:

```
cluster1::> security login modify -user-or-group-name guest
-application ssh -authentication-method publickey
-second-authentication-method none -vserver vs
```
security login password

Modify a password for a user

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The security login password command resets the password for a specified user. The command prompts you for the user's old and new password.

Parameters
-vserver <Vserver Name> - Vserver
This optionally specifies the Vserver name of the login method.

-username <text> - Username
This optionally specifies the user name whose password is to be changed. If you do not specify a user, the command defaults to the user name you are currently using.

Examples
The following command initiates a password change for the 'admin' user account of the 'vs' Vserver.

```
cluster1::> security login password -username admin -vserver vs
```

The following command initiates a password change for the 'vs' Vserver user account named 'admin'. The new password will be encrypted by using the SHA512 password-hashing algorithm.

```
cluster1::*> security login password -username admin -vserver vs -hash-function sha512
```

The following command initiates a password change for the 'vs' Vserver user account named 'admin'. The new password will be encrypted by using the SHA256 password-hashing encryption algorithm.

```
cluster1::*> security login password -username admin -vserver vs -hash-function sha256
```

security login password-prepare-to-downgrade

Reset password features introduced in the Data ONTAP version

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
If the password of the system administrator is not encrypted with an encryption type supported by releases earlier than ONTAP 9.0, this command prompts the administrator for a new password and encrypt it using a supported encryption type on each cluster or at each site in a MetroCluster configuration. In a MetroCluster configuration, this command must be run on both sites. The password for all other users are marked as "expired". This causes them to be re-encrypted using a compatible encryption type. The expired passwords are changed with an internally generated password. The administrator must change the passwords for all users before the users can login. The users are prompted to change their password upon login. This command disables the logging of unsuccessful login attempts. The command must be run by a user with the cluster admin role from a clustershell session on the console device. This user must be unlocked. If you fail to run this command, the revert process fails.

Parameters
-disable-feature-set <downgrade version> - Data ONTAP Version
This parameter specifies the Data ONTAP version that introduced the password feature set.
Examples

The following command disables the logging of unsuccessful login attempts.

```
cluster1::*> security login password prepare-to-downgrade -disable-feature-set 8.3.1
Warning: This command will disable the MOTD feature that prints unsuccessful login
attempts.
Do you want to continue? {y|n}: y
cluster1::>
```

The following command prompts system administrator to enter password and encrypt it with the hashing algorithm supported by releases earlier than Data ONTAP 9.0.

```
cluster1::*> security login password prepare-to-downgrade -disable-feature-set 9.0.0
Warning: If your password is not encrypted with an encryption type supported by
releases earlier than Data ONTAP 9.0.0, this command will prompt you
for a new password and encrypt it using a supported encryption type on
each cluster or at each site in a MetroCluster configuration. In a
MetroCluster configuration, this command must be run on both sites.
The password for all other users are marked as "expired" and
changed to an internally generated password. The administrator must change
the passwords for all users before the users can login. The users are
prompted to change their password upon login.
Do you want to continue? {y|n}:
Enter a new password:
Enter it again:
cluster1::>
```

security login show

Show user login methods

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The security login show command displays the following information about user login methods:

- User name
- Application (console, http, ontapi, rsh, snmp, service-processor, ssh, or telnet)
- Authentication method (community, password, publickey, or usm)
- Role name
- Whether the account is locked
- Whether the user name refers to nsswitch group
- Password hash function

Parameters

```
[-fields <fieldname>, ...
```

If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.
If you specify the `instance` parameter, the command displays detailed information about all fields.

```
[-instance {<Vserver Name>}] - Vserver
```

Displays the login methods that match the specified Vserver name.

```
[-user-or-group-name {<text>}] - User Name or Group Name
```

Displays the login methods that match this parameter value. Value can be a user name or Active Directory, LDAP, or NIS group name.

```
[-application {<text>}] - Application
```

Displays the login methods that match the specified application type. Possible values include console, http, ontapi, rsh, snmp, service-processor, ssh, and telnet.

```
[-authentication-method {<text>}] - Authentication Method
```

Displays the login methods that match the specified authentication method. Possible values include the following:

- `cert` - SSL certificate authentication
- `community` - SNMP community strings
- `domain` - Active Directory authentication
- `nsswitch` - LDAP or NIS authentication
- `password` - Password
- `publickey` - Public-key authentication
- `usm` - SNMP user security model
- `saml` - SAML authentication

```
[-remote-switch-ipaddress {<IP Address>}] - Remote Switch IP Address
```

Displays the login methods that match the specified IP address of the remote switch. The remote switch could be a cluster switch monitored by cluster switch health monitor (CSHM) or a Fibre Channel (FC) switch monitored by MetroCluster health monitor (MCC-HM). This parameter is applicable only when the application is `snmp` and authentication method is `usm` (SNMP user security model).

```
[-role {<text>}] - Role Name
```

Displays the login methods that match the specified role.

```
[-is-account-locked {yes|no}] - Account Locked
```

Displays the login methods that match the specified account lock status.

```
[-comment {<text>}] - Comment Text
```

Displays the login methods that match the specified comment text.

```
[-is-ns-switch-group {yes|no}] - Whether Ns-switch Group
```

This specifies whether `user-or-group-name` is an LDAP or NIS group. Possible values are yes or no.

```
[-hash-function {sha512|sha256}] - Password Hash Function (privilege: advanced)
```

Displays the login methods that match the specified password-hashing algorithm. Possible values are:

- `sha512` - Secure hash algorithm (512 bits)
- `sha256` - Secure hash algorithm (256 bits)
- `md5` - Message digest algorithm (128 bits)
-second-authentication-method \{none|publickey|password|nsswitch\} - Second Authentication Method

Displays the login methods that match the specified authentication method to be used as the second factor. Possible values include the following:

- password - Password
- publickey - Public-key authentication
- nsswitch - NIS or LDAP authentication
- none - default value

Examples

The example below illustrates how to display information about all user login methods:

```
cluster1::> security login show
Vserver: cluster1

User/Group Name     Application Method     Role Name    Locked Method
------------------ ----------- ------------- ---------------- ------ --------------
admin             console     password      admin            no     none
admin             http        password      admin            no     none
admin             ontapi      password      admin            no     none
admin             service-processor password      admin            no     none
admin             ssh         password      admin            no     none
autosupport       console     password      autosupport      no     none

Vserver: vs1.netapp.com

User/Group Name     Application Method     Role Name    Locked Method
------------------ ----------- ------------- ---------------- ------ --------------
vsadmin           http        password      vsadmin          yes    none
vsadmin           ontapi      password      vsadmin          yes    none
vsadmin           ssh         password      vsadmin          yes    none

9 entries were displayed.
```

security login unlock

Unlock a user account with password authentication method

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**
The `security login unlock` command unlocks a specified account, enabling it to access the management interface.

**Parameters**
- `vserver <Vserver Name>` - Vserver
  
  This optionally specifies the Vserver to which the user account belongs.

- `username <text>` - Username

  This specifies the user name of the account that is to be unlocked.

**Examples**
The following command unlocks a user account named jdoe which belongs to the Vserver vs1.
security login whoami

Show the current user and role of this session

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

**Description**
The `security login whoami` command displays the name and role of the user logged in at the current console session. It takes no options or other parameters.

**Examples**
The following example shows that the current session is logged in by using the 'admin' user account:

```
cluster1::> whoami
   (security login whoami)
User: admin
Role: admin
```

**Related references**

SSH login banner

Manage the login banner

The SSH login banner management commands.

security login banner modify

Modify the login banner message

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

**Description**
The `security login banner modify` command modifies the login banner. The login banner is printed just before the authentication step during the SSH and console device login process.

**Parameters**

- `-vserver <Vserver Name>` - Vserver Name
  
  Use this parameter to specify the Vserver whose banner will be modified. Use the name of the cluster admin Vserver to modify the cluster-level message. The cluster-level message is used as the default for data Vservers that do not have a message defined.

- `{ [-message <text>] } - Login Banner Message
  
  This optional parameter can be used to specify a login banner message. If the cluster has a login banner message set, the cluster login banner will be used by all data Vservers as well. Setting a data Vserver's login banner will override the display of the cluster login banner. To reset a data Vserver's login banner to use the cluster login banner, use this parameter with the value `"-"`.

security login commands
If you use this parameter, the login banner cannot contain newlines (also known as end of lines (EOLs) or line breaks). To enter a login banner message with newlines, do not specify any parameter. You will be prompted to enter the message interactively. Messages entered interactively can contain newlines.

Non-ASCII characters must be provided as Unicode UTF-8.

```
[-uri {(ftp|http)://(hostname|IPv4 Address|'['IPv6 Address']')}...] - Download URI for the Banner Message
```

Use this parameter to specify the URI from where the login banner will be downloaded. Note that the message must not exceed 2048 bytes in length. Non-ASCII characters must be provided as Unicode UTF-8.

### Examples

This example shows how to enter a login banner interactively:

```
cluster1::> security login banner modify
Enter the login banner for Vserver "cluster1".
Max size: 2048. Enter a blank line to terminate input. Press Ctrl-C to abort.
012345678901234567890123456789012345678901234567890123456789012345678901234567890
Authorized users only!
```

```
cluster1::>
```

### security login banner show

Display the login banner message

**Availability:** This command is available to cluster and Vserver administrators at the admin privilege level.

**Description**

The `security login banner show` command displays the login banner.

**Parameters**

```
{[-fields <fieldname>, ...]
    If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use -fields ? to display the fields to specify.

[[-instance]]
    If you specify the -instance parameter, the command displays detailed information about all fields.
[-vserver <Vserver Name>] - Vserver Name
    Selects login banners that match the specified value. Use the name of the admin Vserver to specify the cluster-level login banner.
[-message <text>] - Login Banner Message
    Selects login banners that match the specified value. By default, this command will not display unconfigured, or empty, login banners. To display all banners, specify -message *
```

### Examples

The following shows sample output from this command:
security login domain-tunnel commands

The domain-tunnel directory

security login domain-tunnel create

Add authentication tunnel Vserver for administrative Vserver

Availability: This command is available to cluster administrators at the admin privilege level.

Description
This command establishes a gateway (tunnel) for authenticating Windows Active Directory (AD) domain users' access to the cluster.

Before using this command to establish the tunnel, the following must take place:

- You must use the security login create command to create one or more AD domain user accounts that will be granted access to the cluster.
  - The -authmethod parameter of the security login create command must be set to 'domain'.
  - The -username parameter of the security login create command must be set to a valid AD domain user account that is defined in a Windows Domain Controller's Active Directory. The user account must be specified in the format of \<domainname\><username>, where "domainname" is the name of the CIFS domain server.
- You must identify or create a CIFS-enabled data Vserver that will be used for Windows authentication with the Active Directory server. This Vserver is the tunnel Vserver, and it must be running for this command to succeed.

Only one Vserver can be used as the tunnel. If you attempt to specify more than one Vserver for the tunnel, Data ONTAP returns an error. If the tunnel Vserver is stopped or deleted, AD domain users' authentication requests to the cluster will fail.

Parameters
-vserver <vserver> - Authentication Tunnel Vserver

This parameter specifies a data Vserver that has been configured with CIFS. This Vserver will be used as the tunnel for authenticating AD domain users' access to the cluster.

Examples
The following commands create an Active Directory domain user account ('DOMAIN1\Administrator') for the 'cluster1' cluster, create a data Vserver ('vs'), create a CIFS server ('vscifs') for the Vserver, and specify 'vs' as the tunnel for authenticating the domain user access to the cluster.

```bash
cluster1::> security login create -vserver cluster1 -username DOMAIN1\Administrator -application ssh -authmethod domain -role admin
cluster1::> vs server create -vserver vs -rootvolume vol -aggregate aggr -rootvolume-security-style mixed
cluster1::> vs server cifs create -vserver vs -cifs-server vscifs -domain companyname.example.com -ou CN=Computers
cluster1::> security login domain-tunnel create -vserver vs
```
**security login domain-tunnel delete**

Delete authentication tunnel Vserver for administrative Vserver

**Availability:** This command is available to `cluster` administrators at the `admin` privilege level.

**Description**

The `security login domain-tunnel delete` command deletes the tunnel established by the `security login domain-tunnel create` command. An error message will be generated if no tunnel exists.

**Examples**

The following command deletes the tunnel established by `security login domain-tunnel create`.

```
cluster1::> security login domain-tunnel delete
```

**Related references**

- `security login domain-tunnel create` on page 547

---

**security login domain-tunnel modify**

Modify authentication tunnel Vserver for administrative Vserver

**Availability:** This command is available to `cluster` administrators at the `admin` privilege level.

**Description**

The `security login domain-tunnel modify` command modifies or replaces the tunnel Vserver. If a tunnel Vserver is not already specified, it sets the current tunnel Vserver with this Vserver, otherwise, it replaces the current tunnel Vserver with the Vserver that you specify. If the tunnel Vserver is changed, authentication requests via previous Vserver will fail. See `security login domain-tunnel create` for more information.

**Parameters**

```
[-vserver <vserver>] - Authentication Tunnel Vserver
```

This parameter specifies a Vserver that has been configured with CIFS and is associated with a Windows Domain Controller's Active Directory authentication. This Vserver will be used as an authentication tunnel for login accounts so that they can be used with administrative Vservers.

**Examples**

The following command modifies the tunnel Vserver for administrative Vserver.

```
cluster1::> security login domain-tunnel modify -vserver vs
```

**Related references**

- `security login domain-tunnel create` on page 547
security login domain-tunnel show

Show authentication tunnel Vserver for administrative Vserver

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The security login domain-tunnel show command shows the tunnel Vserver that was specified by the security login domain-tunnel create or security login domain-tunnel modify command.

Examples
The example below shows the tunnel Vserver, vs, that is currently used as an authentication tunnel. The output informs you that the table is currently empty if tunnel Vserver has not been specified.

```
cluster1:~> security login domain-tunnel show
Tunnel Vserver: vs
```

security login motd commands
Manage the message of the day (MOTD)
Manage the clustershell message of the day (MOTD).

security login motd modify
Modify the message of the day

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The security login motd modify command updates the message of the day (MOTD).

There are two categories of MOTDs: the cluster-level MOTD and the data Vserver-level MOTD. A user logging in to a data Vserver's clustershell will potentially see two messages: the cluster-level MOTD followed by the Vserver-level MOTD for that Vserver. The cluster administrator can enable or disable the cluster-level MOTD on a per-Vserver basis. If the cluster administrator disables the cluster-level MOTD for a Vserver, a user logging into the Vserver will not see the cluster-level message. Only a cluster administrator can enable or disable the cluster-level message.

Parameters
-vserver <Vserver Name> - Vserver Name
Use this parameter to specify the Vserver whose MOTD will be modified. Use the name of the cluster admin Vserver to modify the cluster-level message.

{ [-message <text>] - Message of the Day (MOTD)
This optional parameter can be used to specify a message. If you use this parameter, the MOTD cannot contain newlines (also known as end of lines (EOLs) or line breaks). If you do not specify any parameter other than the -vserver parameter, you will be prompted to enter the message interactively. Messages entered interactively can contain newlines. Non-ASCII characters must be provided as Unicode UTF-8.

The message may contain dynamically generated content using the following escape sequences:
- `\` - A single backslash character.
- `\b` - No output: supported for compatibility with Linux only.
- `\c` - Cluster name.
- `\d` - Current date as set on the login node.
- `\t` - Current time as set on the login node.
- `\I` - Incoming LIF IP address (prints 'console' for a console login).
- `\l` - Login device name (prints 'console' for a console login).
- `\L` - Last login for the user on any node in the cluster.
- `\m` - Machine architecture.
- `\n` - Node or data Vserver name.
- `\N` - Name of user logging in.
- `\o` - Same as `\O`. Provided for Linux compatibility.
- `\O` - DNS domain name of the node. Note that the output is dependent on the network configuration and may be empty.
- `\r` - Software release number.
- `\s` - Operating system name.
- `\u` - Number of active clustershell sessions on the local node. For the cluster admin: all clustershell users. For the data Vserver admin: only active sessions for that data Vserver.
- `\U` - Same as `\u`, but has 'user' or 'users' appended.
- `\v` - Effective cluster version string.
- `\w` - Active sessions across the cluster for the user logging in ('who').

A backslash followed by any other character is emitted as entered.

```
[[-uri {(ftp|http):/(hostname|IPv4 Address|'[IPv6 Address']')...}] - Download URI for the MOTD

Use this parameter to specify the URI from where the message of the day will be downloaded. Note that the message must not exceed 2048 bytes in length. Non-ASCII characters must be provided as Unicode UTF-8.

[-is-cluster-message-enabled {true|false}] - Is Cluster-level Message Enabled?

Use this parameter to enable or disable the display of the cluster-level MOTD for the specified Vserver.
```

**Examples**

This example shows how to enter a MOTD interactively:

```
cluster1::> security login motd modify -vserver vs0

Enter the message of the day for Vserver "vs0".
Max size: 2048. Enter a blank line to terminate input. Press Ctrl-C to abort.
0 1 2 3 4 5 6 7 8
1234567890123456789012345678901234567890123456789012345678901234567890
```

550  Commands: Manual Page Reference
security login motd show

Display the message of the day

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The security login motd show command displays information about the cluster-level and data Vserver clustershell message of the day (MOTD).

Parameters

`[-fields <fieldname>, ...]`
If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

`[-instance]`
If you specify the `-instance` parameter, the command displays detailed information about all fields.

`[-vserver <Vserver Name>] - Vserver Name`
Selects the message of the day entries that match this parameter value. Use the name of the cluster admin Vserver to see the cluster-level MOTD.

`[-message <text>] - Message of the Day (MOTD)`
Selects the message of the day entries that match this parameter value.

`[-is-cluster-message-enabled (true|false)] - Is Cluster-level Message Enabled?`
Selects the message of the day entries that match this parameter value.

Examples
The following example displays all message of the day entries:

```
cluster1::> security login motd show
Vserver: cluster1
Is the Cluster MOTD Displayed?: true
Message
===================================================================
The cluster is running normally.

Vserver: vs0
Is the Cluster MOTD Displayed?: true
Message
===================================================================
Welcome to the Vserver!
```

2 entries were displayed.

security login publickey commands

Manage public keys
security login publickey create
Add a new public key

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The security login publickey create associates an existing public key with a user account. This command requires that you enter a valid OpenSSH-formatted public key, a user name, index number, and optionally, a comment.

Parameters
-vserver <Vserver Name> - Vserver
This parameter optionally specifies the Vserver of the user for whom you are adding the public key.

-username <text> - Username
This parameter specifies the name of the user for whom you are adding the public key. If you do not specify a user, the user named admin is specified by default.

[-index <integer>] - Index
This parameter specifies an index number for the public key. The default value is the next available index value, starting with zero if it is the first public key created for the user.

-publickey <certificate> - Public Key
This specifies the OpenSSH public key, which must be enclosed in double quotation marks.

[-comment <text>] - Comment
This optionally specifies comment text for the public key. Note that comment text should be enclosed in quotation marks.

Examples
The following command associates a public key with a user named tsmith for Vserver vs1. The public key is assigned index number 5 and the comment text is “This is a new key”.

```
cluster1::> security login publickey create -vserver vs1 -username tsmith -index 5 -publickey "ssh-rsa AAAAB3NzaC1yc2EAAAABIwAAAIEAspH64CYbUsDQCdW22JnK6J /vU9upnKzd2zAk9C1f77aWWRUAfNszZQe51UmQ3ldi8AD0Vfbz576HZPClxNAIza PcdY7bgnmdj9eNGedGr/JNrfzQbLD1h5ybX+72QpQ6cYW8he6DlIoPLob Z6GFmIPxh8VjeU4417W4+s0hG0E=tsmith@publickey.example.com" -comment "This is a new key"
```

security login publickey delete
Delete a public key

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The security login publickey delete command deletes a public key for a specific user. To delete a public key, you must specify a user name and index number.

Parameters
-vserver <Vserver Name> - Vserver
This parameter optionally specifies the Vserver of the user for whom you are adding the public key.
-username <text> - Username
This parameter specifies the name of the user for whom you are deleting a public key. If you do not specify a
user, the user named admin is specified by default.

-index <integer> - Index
This parameter specifies an index number for the public key.

Examples
The following command deletes the public key for the user named tsmith with the index number 5.

```
cluster1:/> security login publickey delete -username tsmith -index 5
```

security login publickey load-from-uri
Load one or more public keys from a URI

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The security login publickey load-from-uri command loads one or more public keys from a Universal Resource
Identifier (URI). To load public keys from a URI, you must specify a user name, the URI from which to load them, and
optionally, whether you want to overwrite the existing public keys.

Parameters
-vserver <vserver name> - Vserver
This parameter optionally specifies the Vserver for the user associated with the public keys.

-username <text> - Username
This parameter specifies the username for the public keys. If you do not specify a username, the username
"admin"is used by default.

-uri {(ftp|http)://(hostname|IPv4 Address|['IPv6 Address']...)} - URI to load from
This parameter specifies the URI from which the public keys will be loaded.

-overwrite (true|false) - Overwrite Entries
This parameter optionally specifies whether you want to overwrite existing public keys. The default value for
this parameter is false. If the value is true and you confirm to overwrite, then the existing public keys are
overwritten with the new public keys. If you use the value false or do not confirm the overwrite, then newly
loaded public keys are appended to the list of existing public keys using the next available index.

Examples
The following command shows how to load public keys for the user named tsmith from the URI ftp://ftp.example.com/
identity.pub. This user's existing public keys are not overwritten.

```
cluster1:/> security login publickey load-from-uri -username tsmith
-.uri ftp://ftp.example.com/identity.pub -overwrite false
```

The following command shows how to load public keys for the user named tsmith from the URI ftp://
ftp.example.com/identity.pub. This user's existing public keys are overwritten if user entered the option 'y' or 'Y'. The
user's existing public keys are not overwritten if user entered the option 'n' or 'N' and the newly loaded public keys are
appended to the list of existing public keys using the next available index. The user and password credentials that you
provide when you use this command are the credentials to access the server specified by the URI.
security login publickey modify

Modify a public key

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The security login publickey modify command modifies a public key and optionally its comment text.

Parameters
- \(-vserver <Vserver Name>\) - Vserver
  Specifies the Vserver for the user associated with the public key.

- \(-username <text>\) - Username
  Specifies the username for the public key. If you do not specify a username, the username 'admin' is used by default.

- \(-index <integer>\) - Index
  Specifies the index number of the public key. The index number of the public key can be found by using the security login publickey show command.

- \([-publickey <certificate>]\) - Public Key
  Specifies the new public key. You must enclose the new public key in double quotation marks.

- \([-comment <text>]\) - Comment
  Specifies the new comment text for the public key.

Examples
The following command modifies the public key at index number 10 for the user named tsmith of Vserver vs1.

```
cluster1::> security login publickey modify -vserver vs1 -username tsmith -index 10 -publickey "ssh-rsa AAAAB3NzaC1yc2EAAAADAQABAAABAQDDD+pFzFgV/2dlowKRFgym9K910H/u+BTG9tCttHJo0y08thmaXT1GCzaoC/12+XX1YKMRhJ09Svo4QQKUXhDCPFXSgR5PNAs39set39ECCLLzmdup1JnkWtX96pQH/bg2g3upFcdC6z9c37uqFtNVPv6Asi1S1/9WDQMjEJzJmRtJudoJeU5GZwZw5ybgTaN1jxDWus9S02C43F/vmoCKVT529UHt4/ePcawHOGT1QOB+Qmm59uTgcfnpg512yKpeNQV8RdYtMdW1Rr4neh1WZrmW7x5N4nXNvteEzr9c8vb9s3yqTX1CKQfD0db+7T7y3X7Mif/qKQY6Fs0vjuvfZD"
```

security login publickey show

Display public keys

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.
Description
The `security login publickey show` command displays information about public keys.

Parameters
{ [-fields <fieldname>, ...] | [-instance] | [-vserver <Vserver Name>] | -username <text> | -index <integer> | -publickey <certificate> | -fingerprint <text> | -bubblebabble <text> | -comment <text> }

If you specify the `-fields <fieldname>`, ... parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

If you specify the `-instance` parameter, the command displays detailed information about all fields.

`-vserver <Vserver Name>` - Vserver
Selects the public keys that match this parameter value.

`-username <text>` - Username
Selects the public keys that match this parameter value.

`-index <integer>` - Index
Selects the public keys that match this parameter value.

`-publickey <certificate>` - Public Key
Selects the public keys that match this parameter value.

`-fingerprint <text>` - Hex Fingerprint
Selects the public keys that match this parameter value.

`-bubblebabble <text>` - Bubblebabble Fingerprint
Selects the public keys that match this parameter value.

`-comment <text>` - Comment
Selects the public keys that match this parameter value.

Examples
The example below displays public key information for the user named tsmith.

```
cluster1::> security login publickey show -username tsmith
UserName: tsmith Index: 5
Public Key: ssh-rsa AAAAB3NzaC1yc2EAAAABAIAEsH64CyUsDQCdW22JnK6J
/vU9upnKzd2zAk9C1f7YaWRUAFNs2Qe51UImQ3Idi8AD0Vfb5T6HZPC1xNAIza
FciDy7hgnmdj99NgedGr/JNrfTCqyLD1hzybX+72DpQB0tYWBHe6eDJloPlob
ZBGfM1PXh8VjeU44i7W4+sOg0E-tsmith@publickey.example.com
Comment: This is a new key
```

security login role commands
Manage access control roles

security login role create
Add an access control role

Availability: This command is available to `cluster` administrators at the `admin` privilege level.
Description
The security login role create command creates an access-control role. An access-control role consists of a role name and a command or directory to which the role has access. It optionally includes an access level (none, readonly, or all) and a query that applies to the specified command or command directory. After you create an access-control role, you can apply it to a management-utility login account by using the security login modify or security login create commands.

Parameters
-vserver <Vserver Name> - Vserver
This optionally specifies the Vserver name associated with the role.

-role <text> - Role Name
This specifies the role that is to be created.

-cmddirname <text> - Command / Directory
This specifies the command or command directory to which the role has access. To specify the default setting, use the special value "DEFAULT".

[-access <Access>] - Access Level
This optionally specifies an access level for the role. Possible access level settings are none, readonly, and all. The default setting is all.

[-query <query>] - Query
This optionally specifies the object that the role is allowed to access. The query object must be applicable to the command or directory name specified by -cmddirname. The query object must be enclosed in double quotation marks (""), and it must be a valid field name.

Examples
The following command creates an access-control role named "admin" for the vs1.example.com Vserver. The role has all access to the "volume" command but only within the "aggr0" aggregate.

  cluster1::> security login role create -role admin -cmddirname volume -query "-aggr aggr0" -access all -vserver vs1.example.com

  security login modify on page 539
  security login create on page 533

security login role delete
Delete an access control role

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The security login role delete command deletes an access-control role.

Parameters
-vserver <Vserver Name> - Vserver
This optionally specifies the Vserver name associated with the role.

-role <text> - Role Name
This specifies the role that is to be deleted.
- `cmddirname <text>` - Command / Directory
  This specifies the command or command directory to which the role has access. To specify the default setting, use the special value "DEFAULT".

**Examples**
The following command deletes an access-control role with the role name readonly and the command access "volume" for Vserver vs.example.com.

```
cluster1::> security login role delete -role readonly -cmddirname volume -vserver vs.example.com
```

**security login role modify**
Modify an access control role

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**
The `security login role modify` command modifies an access-control role.

**Parameters**
- `vserver <Vserver Name>` - Vserver
  This optionally specifies the Vserver name associated with the role.
- `role <text>` - Role Name
  This specifies the role that is to be modified.
- `cmddirname <text>` - Command / Directory
  This specifies the command or command directory to which the role has access. To specify the default setting for a role, use the special value "DEFAULT". This value can be modified only for the roles created for the admin Vserver.
- `[-access <Access>]` - Access Level
  This optionally specifies a new access level for the role. Possible access level settings are none, readonly, and all. The default setting is *all*.
- `[-query <query>]` - Query
  This optionally specifies the object that the role is allowed to access. The query object must be applicable to the command or directory name specified by `cmddirname`. The query object must be enclosed in double quotation marks (""), and it must be a valid field name.

**Examples**
The following command modifies an access-control role with the role name readonly and the command access "volume" to have the access level readonly for Vserver vs.example.com:

```
cluster1::> security login role modify -role readonly -cmddirname volume -access readonly -vserver vs.example.com
```

**security login role prepare-to-downgrade**
Update role configurations so that they are compatible with earlier releases of Data ONTAP

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.
**Description**
The `security login role prepare-to-downgrade` command restores predefined roles of all Vservers earlier than Data ONTAP 8.3.2. You must run this command in advanced privilege mode when prompted to do so during the release downgrade.

**Examples**
The following command restores predefined roles of all Vservers earlier than Data ONTAP 8.3.2.

```
cluster1::*> security login role prepare-to-downgrade
```

---

**security login role show**

Show access control roles

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**
The `security login role show` command displays the following information about access-control roles:

- Role name
- Command or command directory to which the role has access
- Access level (none, read-only, or all)
- Query (detailed view only)

**Parameters**

[-fields <fieldname>, ...]

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

[-instance]

If you specify the `-instance` parameter, the command displays detailed information about all fields.

[-vserver <Vserver Name>] - Vserver

Selects the roles that match this parameter value.

[-role <text>] - Role Name

Selects the roles that match this parameter value. If this parameter and the `-cmddirname` parameter are both used, the command displays detailed information about the specified access-control role.

[-cmddirname <text>] - Command / Directory

Selects the roles that match this parameter value. If this parameter and the `-role` parameter are both used, the command displays detailed information about the specified access-control role.

[-access <Access>] - Access Level

Selects the roles that match this parameter value.

[-query <query>] - Query

Selects the roles that match this parameter value.

**Examples**
The example below displays information about all access-control roles:

```
cluster1::> security login role show
Vserver  RoleName  Command/Directory  Query  AccessLevel
---------  ---------  ----------------  ------  -----------
```

---

558  Commands: Manual Page Reference
security login role show-ontapi

Display the mapping between Data ONTAP APIs and CLI commands

**Availability:** This command is available to cluster and Vserver administrators at the admin privilege level.

**Description**
The security login role show-ontapi command displays Data ONTAP APIs (ONTAPIs) and the CLI commands that they are mapped to.

**Parameters**

`[-fields <fieldname>, ...]`

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

`[-instance]`

If you specify the `-instance` parameter, the command displays detailed information about all fields.

`[-ontapi <text>]` - ONTAPI Name

Use this parameter to view the corresponding CLI command for the specified API.

`[-command <text>]` - CLI Command

Use this parameter to view the corresponding API or APIs for the specified CLI command.

**Examples**
The following command displays all Data ONTAP APIs and their mapped CLI commands:

```
cluster1:/> security login role show-ontapi
ONTAPI                     Command
--------------------------- ---------------------------------------------------
aggr-add                    storage aggregate add-disks
aggr-check-spare-low        storage aggregate check_spare_low
aggr-create                 storage aggregate create
aggr-destroy               storage aggregate delete
aggr-get-filer-info        aggr
aggr-get-iter              storage aggregate show-view
aggr-offline                storage aggregate offline
aggr-online                 storage aggregate online
aggr-options-list-info     storage aggregate show
aggr-rename                 storage aggregate rename
aggr-restrict              storage aggregate restrict
aggr-set-option            storage aggregate modify
autosupport-budget-get     system node autosupport budget show
autosupport-budget-get-iter system node autosupport budget show
autosupport-budget-get-total-records system node autosupport budget show
autosupport-budget-modify   system node autosupport budget modify
autosupport-config-get     system node autosupport show
autosupport-config-get-iter system node autosupport show
autosupport-config-get-total-records system node autosupport show
autosupport-config-modify  system node autosupport show
Press <space> to page down, <return> for next line, or 'q' to quit...
```
The following example displays all Data ONTAP APIs which are mapped to the specified CLI command:

```
cluster1::> security login role show-ontapi -command version
ONTAPI Command
--------------------------- ---------------------------------------------------
system-get-ontapi-version version
system-get-version version
2 entries were displayed.
```

The following example displays the CLI command that is mapped to the specified Data ONTAPI API:

```
cluster1::> security login role show-ontapi -ontapi aggr-create
ONTAPI Name: aggr-create
Command: storage aggregate create
```

**security login role config commands**

Manage the configuration of login roles

**security login role config modify**

Modify local user account restrictions

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**
The security login role config modify command modifies user account and password restrictions.

For the password character restrictions documented below (uppercase, lowercase, digits, etc.), the term "characters" refers to ASCII-range characters only - not extended characters.

**Parameters**

- `vserver <vserver name>` - Vserver
  
  This specifies the Vserver name associated with the profile configuration.

- `role <text>` - Role Name
  
  This specifies the role whose account restrictions are to be modified.

- `[-username-minlength <integer>]` - Minimum Username Length Required
  
  This specifies the required minimum length of the user name. Supported values are 3 to 16 characters. The default setting is 3 characters.

- `[-username-alphanum {enabled|disabled}]` - Username Alpha-Numeric
  
  This specifies whether a mix of alphabetic and numeric characters are required in the user name. If this parameter is enabled, a user name must contain at least one letter and one number. The default setting is disabled.

- `[-passwd-minlength <integer>]` - Minimum Password Length Required
  
  This specifies the required minimum length of a password. Supported values are 3 to 64 characters. The default setting is 8 characters.

- `[-passwd-alphanum {enabled|disabled}]` - Password Alpha-Numeric
  
  This specifies whether a mix of alphabetic and numeric characters is required in the password. If this parameter is enabled, a password must contain at least one letter and one number. The default setting is enabled.
[-passwd-min-special-chars <integer>] - Minimum Number of Special Characters Required in the Password
This specifies the minimum number of special characters required in a password. Supported values are from 0 to 64 special characters. The default setting is 0, which requires no special characters.

[-passwd-expiry-time <unsigned32_or_unlimited>] - Password Expires In (Days)
This specifies password expiration in days. A value of 0 means all passwords associated with the accounts in the role expire now. The default setting is unlimited, which means the passwords never expire.

[-require-initial-passwd-update {enabled|disabled}] - Require Initial Password Update on First Login
This specifies whether users must change their passwords when logging in for the first time. Initial password changes can be done only through SSH or serial-console connections. The default setting is disabled.

[-max-failed-login-attempts <integer>] - Maximum Number of Failed Attempts
This specifies the allowed maximum number of consecutive invalid login attempts. When the failed login attempts reach the specified maximum, the account is automatically locked. The default is 0, which means failed login attempts do not cause an account to be locked.

[-lockout-duration <integer>] - Maximum Lockout Period (Days)
This specifies the number of days for which an account is locked if the failed login attempts reach the allowed maximum. The default is 0, which means the accounts will be locked for 1 day.

[-disallowed-reuse <integer>] - Disallow Last 'N' Passwords
This specifies the number of previous passwords that are disallowed for reuse. The default setting is six, meaning that the user cannot reuse any of their last six passwords. The minimum allowed value is 6.

[-change-delay <integer>] - Delay Between Password Changes (Days)
This specifies the number of days that must pass between password changes. The default setting is 0.

[-delay-after-failed-login <integer>] - Delay after Each Failed Login Attempt (Secs)
This specifies the amount of delay observed by the system in seconds upon invalid login attempts. The default setting is 4 seconds.

[-passwd-min-lowercase-chars <integer>] - Minimum Number of Lowercase Alphabetic Characters Required in the Password
This specifies the minimum number of lowercase characters required in a password. Supported values are from 0 to 64 lowercase characters. The default setting is 0, which requires no lowercase characters.

[-passwd-min-uppercase-chars <integer>] - Minimum Number of Uppercase Alphabetic Characters Required in the Password
This specifies the minimum number of uppercase characters required in a password. Supported values are from 0 to 64 uppercase characters. The default setting is 0, which requires no uppercase characters.

[-passwd-min-digits <integer>] - Minimum Number of Digits Required in the Password
This specifies the minimum number of digits required in a password. Supported values are from 0 to 64 digits characters. The default setting is 0, which requires no digits.

[-passwd-expiry-warn-time <unsigned32_or_unlimited>] - Display Warning Message Days Prior to Password Expiry (Days)
This specifies the warning period for password expiry in days. A value of 0 means warn user about password expiry upon every successful login. The default setting is unlimited, which means never warn about password expiry.

[-account-expiry-time <unsigned32_or_unlimited>] - Account Expires in (Days)
This specifies account expiration in days. The default setting is unlimited, which means the accounts never expire. The account expiry time must be greater than account inactive limit.
[-account-inactive-limit <unsigned32_or_unlimited>] - Maximum Duration of Inactivity before Account Expiration (Days)

This specifies inactive account expiry limit in days. The default setting is unlimited, which means the inactive accounts never expire. The account inactive limit must be less than account expiry time.

Examples
The following command modifies the user-account restrictions for an account with the role name admin for a Vserver named vs. The minimum size of the password is set to 12 characters.

```
cluster1::> security login role config modify -role admin -vserver vs -passwd-minlength 12
```

security login role config reset

Reset RBAC characteristics supported on releases later than Data ONTAP 8.1.2

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
The security login role config reset command resets the following role based access control (RBAC) characteristics to their default values. The system prompts you to run this command if you revert to Data ONTAP 8.1.2 or earlier. If you do not reset these characteristics, the revert process will fail.

- Minimum number of special characters required in password ("0")
- Password-expiration time, in days ("unlimited")
- Whether the password must be changed at the initial login ("disabled")
- Maximum number of failed login attempts permitted before the account is locked out ("0")
- Number of days that the user account is locked out after the maximum number of failed login attempts is reached ("0")

Examples
The following command resets the above mentioned RBAC characteristics of all cluster and Vserver roles to their default values.

```
cluster1::> security login role config reset
```

security login role config show

Show local user account restrictions

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The security login role config show command displays the following information about account restrictions for management-utility user accounts:

- Role name -role
- Minimum size of the password, in characters -passwd-minlength
- Whether the password requires alphanumeric characters -passwd-alphanum
- Number of previous passwords that cannot be reused -disallowed-reuse
• Minimum number of days that must elapse before users can change their passwords `-change-delay`

You can display detailed information about the restrictions on a specific account by specifying the `-role` parameter. This adds the following information:

• Minimum length of the user name, in characters `-username-minlength`
• Whether the user name requires alphanumeric characters `-username-alphanum`
• Minimum length of the password, in characters `-passwd-minlength`
• Whether the password requires alphanumeric characters `-passwd-alphanum`
• Minimum number of special characters required in password `-passwd-min-special-chars`
• Minimum number of lowercase characters required in password `-passwd-min-lowercase-chars`
• Minimum number of uppercase characters required in password `-passwd-min-uppercase-chars`
• Minimum number of digits required in password `-passwd-min-digits`
• Minimum number of days that must elapse before users can change their passwords `-change-delay`
• Whether the password must be changed at the initial login `-require-initial-passwd-update`
• Password-expiration time, in days `-passwd-expiry-time`
• Display warning message days prior to password expiry `-passwd-expiry-warn-time`
• Number of previous passwords that cannot be reused `-disallowed-reuse`
• Maximum number of failed login attempts permitted before the account is locked out `-max-failed-login-attempts`
• Number of days for which the user account is locked after the maximum number of failed login attempts is reached `-lockout-duration`
• Account-expiration time, in days `-account-expiry-time`
• Maximum duration of inactivity before account expiration, in days `-account-inactive-limit`
• Delay after each failed login attempt, in secs `-delay-after-failed-login`

Parameters

`{-fields <fieldname>,...}
If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

`{-instance}}
If you specify the `-instance` parameter, the command displays detailed information about all fields.

`{-vserver <vserver name>}` - Vserver
Selects the profile configurations that match this parameter value

`{-role <text>}` - Role Name
If this parameter is specified, the command displays detailed information about restrictions for the specified user account.

`{-username-minlength <integer>}` - Minimum Username Length Required
Selects the profile configurations that match this parameter value.
[-username-alphanum {enabled|disabled}] - Username Alpha-Numeric
Selects the profile configurations that match this parameter value. Enabled means a user name must contain both letters and numbers.

[-passwd-minlength <integer>] - Minimum Password Length Required
Selects the profile configurations that match this parameter value.

[-passwd-alphanum {enabled|disabled}] - Password Alpha-Numeric
Selects the profile configurations that match this parameter value. Enabled means a password must contain both letters and numbers.

[-passwd-min-special-chars <integer>] - Minimum Number of Special Characters Required in the Password
Selects the profile configurations that match this parameter value.

[-passwd-expiry-time <unsigned32_or_unlimited>] - Password Expires In (Days)
Selects the profile configurations that match this parameter value.

[-require-initial-passwd-update {enabled|disabled}] - Require Initial Password Update on First Login
Selects the profile configurations that match this parameter value.

[-max-failed-login-attempts <integer>] - Maximum Number of Failed Attempts
Selects the profile configurations that match this parameter value.

[-lockout-duration <integer>] - Maximum Lockout Period (Days)
Selects the profile configurations that match this parameter value.

[-disallowed-reuse <integer>] - Disallow Last 'N' Passwords
Selects the profile configurations that match this parameter value.

[-change-delay <integer>] - Delay Between Password Changes (Days)
Selects the profile configurations that match this parameter value.

[-delay-after-failed-login <integer>] - Delay after Each Failed Login Attempt (Secs)
Selects the profile configurations that match this parameter value.

[-passwd-min-lowercase-chars <integer>] - Minimum Number of Lowercase Alphabetic Characters Required in the Password
Selects the profile configurations that match this parameter value.

[-passwd-min-uppercase-chars <integer>] - Minimum Number of Uppercase Alphabetic Characters Required in the Password
Selects the profile configurations that match this parameter value.

[-passwd-min-digits <integer>] - Minimum Number of Digits Required in the Password
Selects the profile configurations that match this parameter value.

[-passwd-expiry-warn-time <unsigned32_or_unlimited>] - Display Warning Message Days Prior to Password Expiry (Days)
Selects the profile configurations that match this parameter value.

[-account-expiry-time <unsigned32_or_unlimited>] - Account Expires in (Days)
Selects the profile configurations that match this parameter value.

[-account-inactive-limit <unsigned32_or_unlimited>] - Maximum Duration of Inactivity before Account Expiration (Days)
Selects the profile configurations that match this parameter value.

Examples
The example below displays restriction information about all user accounts:
security login rest-role commands

Manage access control rest roles

security login rest-role create

Add an access control REST role

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The security login rest-role create command creates an access-control role. An access-control role consists of a role name and a api to which the role has access. It optionally includes an access level (none, readonly, or all) for api. After you create an access-control role, you can apply it to a management-utility login account by using the security login modify or security login create commands.

Parameters
- `vserver <Vserver Name>` - Vserver
  This optionally specifies the Vserver name associated with the role.
- `role <text>` - Role Name
  This specifies the role that is to be created.
- `api <text>` - api path
  This specifies the api to which the role has access.
- `access <Access>` - Access Level
  This optionally specifies an access level for the role. Possible access level settings are none, readonly, and all. The default setting is all.

Examples
The following command creates an access-control role named "admin" for the vs1.example.com Vserver. The role has all access to the api "/api/storage/volume" but only within the "aggr0" aggregate.

```
cluster1::> security login rest-role create -role admin -api /api/storage/volume -access all -vserver vs1.example.com
```

Related references
security login modify on page 539
security login create on page 533
security login rest-role delete

Delete an access REST control role

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The security login rest-role delete command deletes an access-control role.

Parameters
-vserver <Vserver Name> - Vserver
This optionally specifies the Vserver name associated with the role.

-role <text> - Role Name
This specifies the role that is to be deleted.

-api <text> - api path
This specifies the api to which the role has access.

Examples
The following command deletes an access-control role with the role name readonly and the api "/api/storage/volume" for Vserver vs.example.com:

cluster1::> security login rest-role delete -role readonly -api /api/storage/volume -vserver vs.example.com

security login rest-role modify

Modify an access REST control role

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The security login rest-role modify command modifies an access-control role.

Parameters
-vserver <Vserver Name> - Vserver
This optionally specifies the Vserver name associated with the role.

-role <text> - Role Name
This specifies the role that is to be modified.

-api <text> - api path
This specifies the api to which the role has access.

[-access <Access>] - Access Level
This optionally specifies a new access level for the role. Possible access level settings are none, readonly, and all. The default setting is all.

Examples
The following command modifies an access-control role with the role name readonly and the api access "/api/storage/volume" to have the access level readonly for Vserver vs.example.com:
security login rest-role modify

-role readonly -api /api/storage/volume -access readonly -vserver vs.example.com

security login rest-role show

Show access control REST roles

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The security login rest-role show command displays the following information about access-control roles:

- vserver
- Role name
- api to which the role has access
- Access level (none, read-only, or all)

Parameters

{-fields <fieldname>,...}
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

{-instance}
If you specify the -instance parameter, the command displays detailed information about all fields.

{-vserver <Vserver Name> } - Vserver
Selects the roles that match this parameter value.

{-role <text>} - Role Name
Selects the roles that match this parameter value. If this parameter and the -api parameter are both used, the command displays detailed information about the specified access-control role.

{-api <text>} - api path
Selects the roles that match this parameter value. If this parameter and the -role parameter are both used, the command displays detailed information about the specified access-control role.

{-access <Access>} - Access Level
Selects the roles that match this parameter value.

Examples
The example below displays information about all access-control roles:

cluster1::> security login rest-role show

<table>
<thead>
<tr>
<th>Role</th>
<th>Access</th>
<th>Vserver</th>
<th>Name</th>
<th>API</th>
<th>Level</th>
</tr>
</thead>
<tbody>
<tr>
<td>vs</td>
<td>vserver</td>
<td>/api</td>
<td>vsadmin</td>
<td>none</td>
<td></td>
</tr>
<tr>
<td>cluster1</td>
<td>readonly</td>
<td>/api/storage</td>
<td>none</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
**security protocol commands**

Manage application configuration

**security protocol modify**

Modify application configuration options

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

**Description**
The `security protocol modify` command modifies the existing cluster-wide configuration of RSH and Telnet. Enable RSH and Telnet in the cluster by setting the enabled field as true.

**Parameters**
- `application <text>` - application
  Selects the application. Supported values are *rsh* and *telnet*.
- `[-enabled {true|false}] - enabled`
  Enables or disables the corresponding application. The default value is *false*.

**Examples**
The following command enables RSH in the cluster. The default setting for RSH is *false*:

```
cluster1::> security protocol modify -application rsh -enabled true
```

The following command enables Telnet in the cluster. The default setting for Telnet is *false*:

```
cluster1::> security protocol modify -application telnet -enabled true
```

**security protocol show**

Show application configuration options

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

**Description**
The `security protocol show` command displays the cluster-wide configuration of RSH and Telnet in the cluster in advanced privilege mode. RSH and Telnet are disabled by default. Use the `security protocol modify` command to change the RSH and Telnet configuration that the cluster supports.

**Parameters**
- `[-fields <fieldname>, ...]`
  If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.
- `[-instance]`
  If you specify the `-instance` parameter, the command displays detailed information about all fields.
- `[-application <text>] - application`
  Displays the insecure applications in the cluster.
[|-enabled [true|false]] - enabled

Displays whether the application is enabled or disabled in the cluster.

Examples

The following example shows the default security protocol configurations for a cluster:

```
cluster1::> security protocol show
Application        Enabled
------------------- ---------------
rsh                 false
telnet              false
```

The following example shows the security protocol configuration after RSH and Telnet have been enabled:

```
cluster1::> security protocol show
Application        Enabled
------------------- ---------------
rsh                 true
telnet              true
```

security protocol ssh commands

Manage SSH global configuration

security protocol ssh modify

Modify the SSH configuration

Availability: This command is available to cluster administrators at the advanced privilege level.

Description

The `security protocol ssh modify` command modifies the existing cluster-wide configuration of SSH.

Parameters

[-per-source-limit <integer>] - Per-Source Limit

Modifies the maximum number of SSH instances per source IP address on a per-node basis.

[-max-instances <integer>] - Maximum Number of Instances

Modifies the maximum number of SSH instances that can be handled on a per-node basis.

[-connections-per-second <integer>] - Connections Per Second

Modifies the maximum number of SSH connections per second on a per-node basis.

Examples

The following example modifies cluster-wide SSH configuration:

```
cluster1::*> security protocol ssh modify -per-source-limit 30 -max-instances 60 -connections-per-second 5
```
security protocol ssh show

Show the SSH configuration

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
The security protocol ssh show command displays the cluster-wide SSH configuration in advanced privilege mode. Use the security protocol ssh modify command to change the SSH configuration that the cluster supports.

Examples
The following example displays cluster-wide SSH configuration:

```
cluster1::*> security protocol ssh show
  Per-Source Limit: 32
  Maximum Number of Instances: 64
  Connections Per Second: 10
```

security protocol ssh modify on page 569

Manage SAML authentication single sign-on configuration

Manage SAML authentication single sign-on configuration

These commands configure the Security Assertion Markup Language (SAML) Service Provider (SP) single sign-on configuration. SAML SP functionality provides the ability for Data ONTAP to use an Identity Provider (IdP) for authentication.

security saml-sp create

Configure SAML service provider for authentication

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The security saml-sp create command configures ONTAP with Security Assertion Markup Language (SAML) Service Provider (SP) for single sign-on authentication. This command does not enable SAML SP, it just configures it. Configuring and enabling SAML SP is a two-step process:

- Create a SAML SP configuration using security saml-sp create command.
- Enable SAML SP by using security saml-sp modify -is-enabled true

After the SAML SP configuration is created, it cannot be modified. It must be deleted and created again to change any settings.

Note: This restarts the web server. Any HTTP/S connections that are active will be disrupted.

Parameters
-idp-uri {(ftp|http)://(hostname|IPv4 Address|'['IPv6 Address']')...} - Identity Provider (IdP)

Metadata Location
This is the URI of the desired identity provider's (IdP) metadata.
[-sp-host <Remote InetAddress>] - SAML Service Provider Host
This specifies the SAML service provider host IP address.

{-cert-ca <text>} - Server Certificate Issuing CA
This specifies the service provider's certificate issuing CA.

{-cert-serial <text>} - Server Certificate Serial Number
This specifies the service provider's certificate's serial number.

|[{-cert-common-name <FQDN or Custom Common Name}>]} - Server Certificate Common Name
This specifies the service provider certificate's common name.

[-verify-metadata-server {true|false}] - Verify IdP Metadata Server Identity
When the IdP metadata is downloaded, the identity of the server hosting the metadata is verified using transport layer security (TLS), validating the server's X.509 certificate against the list of certificate authorities (CAs) in Data ONTAP, and verifying that the host in the server certificate matches the host in the URI (the idp-uri field). This verification can be bypassed by setting this field to false. Bypassing the server verification is not recommended as the server can not be trusted that way, but will be necessary to use non-TLS URIs, e.g. with the "http" scheme, or when the server certificates are self-signed. If the server's certificate was signed by a CA that is not installed in Data ONTAP, the security certificate install -type server-ca command can be used to install it.

[-foreground {true|false}] - Foreground Process
When this parameter is set to false the command runs in the background as a job. The default is true, which causes the command to return after the operation completes.

Examples
The following example configures ONTAP with SAML SP IdP information:

```
cluster1::> security saml-sp create -idp-uri http://public-idp-uri -sp-host 1.1.1.1
cluster1::>
```

Related references
security saml-sp modify on page 572

security saml-sp delete
Delete SAML service provider for authentication

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The security saml-sp delete command is used to remove the Security Access Markup Language (SAML) Service Provider (SP). Running this command frees resources used by the SP. SAML SP services will no longer be available after the SP is removed.

If the SAML SP is currently enabled, it is necessary to first use security saml-sp modify -is-enabled false prior to security saml-sp delete. The security saml-sp modify -is-enabled false command must be issued by a password authenticated console application user or from a SAML authenticated command interface.

Note: This restarts the web server. Any HTTP/S connections that are active will be disrupted.
Examples
The following example unconfigures SAML SP:

```
cluster1::> security saml-sp delete
cluster1::>
```

Related references
- `security saml-sp modify` on page 572

**security saml-sp modify**
Modify SAML service provider authentication

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**
The `security saml-sp modify` command modifies the Security Assertion Markup Language (SAML) Service Provider (SP) configuration for single sign-on authentication. This command is used to enable or disable an existing SAML SP, `security saml-sp modify -is-enabled true` or `false` respectively.

This command will check the validity of the current SAML SP configuration before enabling the SP. Also, it is necessary to use this command with the `--is-enabled false` parameter prior to deleting an existing SAML SP configuration. SAML SP can only be disabled in this way by a password authenticated console application user or from a SAML authenticated command interface. The delete command must be used if the SAML configuration settings are to be changed, as only the `is-enabled` parameter can be modified.

**Note:** This may restart the web server. Any HTTP/S connections that are active may be disrupted.

**Parameters**

[-is-enabled {true | false}] - SAML Service Provider Enabled

Use this parameter to enable or disable the SAML SP.

Examples
The following example enables SAML SP:

```
cluster1::> security saml-sp modify -is-enabled true
cluster1::>
```

**security saml-sp repair**
Repair a failed SAML SP configuration

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

**Description**
The `security saml-sp repair` command attempts to repair a failed SAML SP configuration on a given node. The status of the individual nodes can be viewed using the `security saml-sp status show` command.

**Note:** This restarts the web server. Any active HTTP/S requests to the web server will be disrupted.
Parameters

- `node {<nodename>|local}` - Node

  This identifies a single node that matches the input. The repair job will run on this node.

- `foreground {true|false}` - Foreground Process

  When this parameter is set to `false` the command runs in the background as a job. The default is `true`, which causes the command to return after the operation completes.

Examples

The following example repairs a failed SAML SP configuration:

```
cluster1:> security saml-sp repair -node node-2
Warning: This restarts the web server. Any active HTTP/S requests to the web server will be disrupted
Do you want to continue? {y|n}: y
cluster1:>
```

Related references

`security saml-sp status show` on page 574

security saml-sp show

Display SAML service provider for authentication

Availability: This command is available to `cluster` administrators at the `admin` privilege level.

Description

The `security saml-sp show` command displays the Security Assertion Markup Language (SAML) Service Provider (SP) configuration.

The **Identity Provider** (IdP) **URI** indicates the URI of the desired IdP's metadata.

The **Service Provider** (SP) **host** indicates the IP address containing SAML SP metadata.

The **Certificate Common Name** indicates the SAML SP certificate's common name.

The **Certificate Serial** indicates the SAML SP certificate's serial number.

Examples

The following example displays the SAML SP configuration:

```
cluster1:/> security saml-sp show
    Identity Provider URI: https://www.my.idp.com
    Service Provider Host: 1.1.1.1
    Certificate Name: mycert
    Certificate Serial: 1234abcd
    Is SAML Enabled: false
```
security saml-sp status commands

The status directory

security saml-sp status show

Display SAML service provider configuration status

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
The security saml-sp status show command displays the SAML Service Provider (SP) status for all nodes in the cluster.

Parameters

{ [-fields <fieldname>, ...]

If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

| [-instance ]

If you specify the -instance parameter, the command displays detailed information about all fields.

[-node {<nodename>|local}] - Node

This identifies the node in the cluster.

[-status {not-configured|config-in-progress|config-failed|config-success}] - Update Status

This identifies the SAML SP status on the specified node.

[-error-text <text>] - Error Text

This identifies the error text associated with the latest saml SP update for this node.

[-is-enabled {true|false}] - SAML Service Provider Enabled

When this parameter is set to true it indicates that the SAML SP is enabled on this node. Similarly, when this parameter is set to false, it indicates that the SAML SP is not enabled on this node.

Examples

The following example displays the SAML SP status information for all nodes in the cluster.

```
cluster::security saml-sp status> show
Node                  SAML SP Status      Enabled
-----------------------------------------------
cluster-node1          not-configured    false
cluster-node2          not-configured    false
2 entries were displayed.
cluster:::*>
```

Security Session Commands

Manage CLI, ONTAPI, and REST sessions and view request statistics

The security session commands provide statistics to monitor management session activity and limit configurations to control management session activity for specific categories.
security session kill-cli

Kill a CLI session

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The security session kill-cli command is used to terminate CLI sessions. If the session being killed is actively processing a non-read command, the kill will wait until the command is complete before terminating the session. If the session being killed is actively processing a read (show) command, the kill will wait until the current row is returned before terminating the session.

Parameters
-node {<nodename>|local} - Node
Selects the sessions that match this parameter value. This identifies the node that is processing the session.

[-interface {cli|ontapi|rest}] - Interface
Selects the sessions that match this parameter value. This identifies the interface (CLI, ONTAPI, or REST) that is processing the session.

[-start-time <MM/DD HH:MM:SS>] - Start Time
Selects the sessions that match this parameter value. This identifies the start time of the current active session.

-session-id <integer> - Session ID
Selects the sessions that match this parameter value. This number uniquely identifies a management session within a given node.

[-vserver <vserver>] - Vserver
Selects the sessions that match this parameter value. This identifies the Vserver associated with this management session.

[-username <text>] - Username
Selects the sessions that match this parameter value. This identifies the authenticated user associated with this management session.

[-application <text>] - Client Application
Selects the sessions that match this parameter value. This identifies the calling application by name.

[-location <text>] - Client Location
Selects the sessions that match this parameter value. This identifies the location of the calling client application. This is typically the IP address of the calling client, or "console" or "localhost" for console or localhost connections.

[-idle-seconds <integer>] - Idle Seconds
Selects the sessions that match this parameter value. When a session is not actively executing a command request (the session is idle), this indicates the time (in seconds) since the last request completed.

[-state {pending|active|idle}] - Session State
Selects the sessions that match this parameter value. This identifies the state (pending, active, or idle) of the session. The state is "pending" if it hit a session limit and the session is waiting for another session to end. The state is "idle" for CLI sessions that are waiting at the command prompt. The state is "active" if the session is actively working on a request.

[-request <text>] - Active Command
Selects the sessions that match this parameter value. This identifies the request (command) that is currently being handled by the session.
Examples

The following example illustrates killing a CLI session by specifying the node and the session id.

```
cluster1::> security session show -node node1
Node: node1               Interface: cli                                   Idle
Start Time     Sess ID Application Location           Vserver Username  Seconds
-------------- ------- ----------- ------------ ------------- -------- --------
03/27 16:58:13 1358    console     console           cluster1 admin           -
Active Seconds: 0  Request: security session show
03/27 16:58:17 1359    ssh         10.98.16.164      cluster1 admin         650
2 entries were displayed.
```

```
cluster1::> security session kill-cli -node node1 -session-id 1359
1 entry was acted on.
```

```
cluster1::> security session show -node node1
Node: node1               Interface: cli                                   Idle
Start Time     Sess ID Application Location           Vserver Username  Seconds
-------------- ------- ----------- ------------ ------------- -------- --------
03/27 16:58:13 1358    console     console           cluster1 admin           -
Active Seconds: 0  Request: security session show
cluster1::>
```

The following example illustrates killing a CLI session by specifying the node and specifying a query on idle-seconds.

```
cluster1::> security session show -node node1
Node: node1               Interface: cli                                   Idle
Start Time     Sess ID Application Location           Vserver Username  Seconds
-------------- ------- ----------- ------------ ------------- -------- --------
03/27 16:58:13 1358    console     console           cluster1 admin           -
Active Seconds: 0  Request: security session show
03/27 17:13:36 1479    ssh         10.98.16.164      cluster1 admin          83
2 entries were displayed.
```

```
cluster1::> security session kill-cli -node node1 -session-id * -idle-seconds > 80
1 entry was acted on.
```

```
cluster1::> security session show
Node: node1               Interface: cli                                   Idle
Start Time     Sess ID Application Location           Vserver Username  Seconds
-------------- ------- ----------- ------------ ------------- -------- --------
03/27 17:13:36 1479    ssh         10.98.16.164      cluster1 admin          83
Active Seconds: 0  Request: security session show
cluster1::>
```

security session show

Show current CLI, ONTAPI, and REST sessions

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The security session show command displays all active management sessions across the cluster.
Parameters

{[-fields <fieldname>, ...]}

If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

{[-instance ]}

If you specify the -instance parameter, the command displays detailed information about all fields.

[-node {<nodename> | local}] - Node

Selects the sessions that match this parameter value. This identifies the node that is processing the session.

[-interface {cli|ontapi|rest}] - Interface

Selects the sessions that match this parameter value. This identifies the interface (CLI, ONTAPI, or REST) that is processing the session.

[-start-time <MM/DD HH:MM:SS>] - Start Time

Selects the sessions that match this parameter value. This identifies the start time of the current active session.

[-session-id <integer>] - Session ID

Selects the sessions that match this parameter value. This number uniquely identifies a management session within a given node.

[-vserver <vserver>] - Vserver

Selects the sessions that match this parameter value. This identifies the Vserver associated with this management session.

[-username <text>] - Username

Selects the sessions that match this parameter value. This identifies the authenticated user associated with this management session.

[-application <text>] - Client Application

Selects the sessions that match this parameter value. This identifies the calling application by name.

[-location <text>] - Client Location

Selects the sessions that match this parameter value. This identifies the location of the calling client application. This is typically the IP address of the calling client, or "console" or "localhost" for console or localhost connections.

[-ipspace <IPspace>] - IPspace of Location

Selects the sessions that match this parameter value. This identifies the IPspace of the client location.

[-total <integer>] - Total Requests

Selects the sessions that match this parameter value. This identifies the total number of requests that have been made thus far in the active session. The following commands are not counted: top, up, cd, rows, history, exit.

[-failed <integer>] - Failed Requests

Selects the sessions that match this parameter value. This identifies the number of requests that have failed for any reason (including if they were blocked by configured limits).

[-max-time <integer>] - Maximum Time (ms)

Selects the sessions that match this parameter value. This identifies the maximum amount of time (in milliseconds) that any request took for this session.

[-last-time <integer>] - Last Time (ms)

Selects the sessions that match this parameter value. This identifies the amount of time (in milliseconds) that the last request took for this session.

[-total-seconds <integer>] - Total Seconds

Selects the sessions that match this parameter value. This identifies the total time (in seconds) that has been taken by all completed requests for the current session; it does not include session idle time.
[-state {pending|active|idle}] - Session State

Selects the sessions that match this parameter value. This identifies the state (pending, active, or idle) of the session. The state is "pending" if it hit a session limit and the session is waiting for another session to end. The state is "idle" for CLI sessions that are waiting at the command prompt. The state is "active" if the session is actively working on a request.

[-request <text>] - Request Input

Selects the sessions that match this parameter value. This identifies the request (command) that is currently being handled by the session.

[-idle-seconds <integer>] - Idle Seconds

Selects the sessions that match this parameter value. When a session is not actively executing a command request (the session is idle), this indicates the time (in seconds) since the last request completed.

[-active-seconds <integer>] - Active Seconds

Selects the sessions that match this parameter value. When a session is actively executing a command request, this indicates the time (in seconds) since the current request started.

Examples

The following example illustrates displaying all active sessions across the cluster. In this example, we see one active session on node node2 from the console application. We also see three active sessions on node node1. One is from the console application and two are from the ssh application. Also one of the ssh sessions is from user diag and the other ssh session is from user admin.

```
cluster1::> security session show
Node: node1               Interface: cli                                   Idle
Start Time     Sess ID Application Location           Vserver Username  Seconds
-------------- ------- ----------- ------------ ------------- -------- --------
03/27 16:58:13 1358    console     console           cluster1 admin          -
Active Seconds: 0  Request: security session show
03/27 17:17:04 1514    ssh         10.98.16.164      cluster1 admin         139
03/27 17:17:29 1515    ssh         10.98.16.164      cluster1 diag          115
Node: node2               Interface: cli                                   Idle
Start Time     Sess ID Application Location           Vserver Username  Seconds
-------------- ------- ----------- ------------ ------------- -------- --------
03/27 17:18:54 1509    console     console           cluster1 admin          23
4 entries were displayed.
```

The following example illustrates displaying all active sessions that have been idle for longer than 500 seconds.

```
cluster1::> security session show -idle-seconds > 500
Node: node1               Interface: cli                                   Idle
Start Time     Sess ID Application Location           Vserver Username  Seconds
-------------- ------- ----------- ------------ ------------- -------- --------
03/27 17:17:04 1514    ssh         10.98.16.164      cluster1 admin         607
03/27 17:17:29 1515    ssh         10.98.16.164      cluster1 diag          583
2 entries were displayed.
```
Security Session Limit Commands

Manage management session limits

These commands allow management session limits to be configured for specific categories, including application, location, request, user, and Vserver. The default limits can be overridden for specific values within each category by using advanced privilege level commands.

security session limit create

Create default session limit

Availability: This command is available to cluster administrators at the admin privilege level.

Description
This command allows creation of a default management session limit that does not yet exist. The default limits can be overridden for specific values within each category by using advanced privilege level commands.

Parameters

- **-interface {cli|ontapi|rest} - Interface**
  The interface (CLI, ONTAPI, or REST) to which the limit applies.

- **-category {application|location|request|user|vserver} - Category**
  The session type for this default limit. The following categories are supported: application, location, request, user, Vserver.

- **-max-active-limit <integer> - Max-Active Limit**
  The maximum number of concurrent sessions allowed for this interface and category.

Examples

The following example illustrates creating a default limit for management sessions using the same application.

```
cluster1::> security session limit create -interface ontapi -category application -max-active-limit 8
```

security session limit delete

Delete default session limit

Availability: This command is available to cluster administrators at the admin privilege level.

Description
This command allows deletion of a default management session limit.

Parameters

- **-interface {cli|ontapi|rest} - Interface**
  The interface (CLI, ONTAPI, or REST) to which the limit applies.

- **-category {application|location|request|user|vserver} - Category**
  The session type for this default limit. The following categories are supported: application, location, request, user, Vserver.
Examples

The following example illustrates deleting all default limits for CLI management sessions.

```
cluster1::> security session limit delete -interface cli -category *
3 entries were deleted.
```

security session limit modify

Modify default session limit

Availability: This command is available to cluster administrators at the admin privilege level.

Description

This command allows modification of a default management session limit.

Parameters

- `--interface {cli|ontapi|rest} - Interface`
  
  The interface (CLI, ONTAPI, or REST) to which the limit applies.

- `--category {application|location|request|user|vserver} - Category`
  
  The session type for this default limit. The following categories are supported: application, location, request, user, Vserver.

- `--max-active-limit <integer> - Max-Active Limit`
  
  The maximum number of concurrent sessions allowed for this interface and category.

Examples

The following example illustrates modifying the default limit for CLI management sessions from the same location.

```
cluster1::> security session limit modify -interface cli -category location -max-active-limit 4
```

security session limit show

Show default session limits

Availability: This command is available to cluster administrators at the admin privilege level.

Description

This command shows the default management session limits that have been configured for each interface and category.

Parameters

- `[-fields <fieldname>, ...]`
  
  If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

- `[-instance ]`
  
  If you specify the -instance parameter, the command displays detailed information about all fields.
[\-interface {cli|ontapi|rest}] - Interface
Selects the sessions that match this parameter value. This identifies the interface (CLI, ONTAPI, or REST) to which the limit applies.

[\-category {application|location|request|user|vserver}] - Category
Selects the sessions that match this parameter value. This identifies the category for the limit. The following categories are supported: application, location, request, user, and Vserver.

[\-max-active-limit <integer>] - Max-Active Limit
Selects the sessions that match this parameter value. This identifies the configured limit that is used to throttle or reject requests.

Examples
The following example illustrates displaying the default limits for management sessions.

```
cluster1::> security session limit show
Interface Category    Max-Active
--------- ----------- ----------
cli       user                 2
cli       vserver              4
ontapi    vserver              2
3 entries were displayed.
```

Security Session Application Limit Commands
Manage per-application session limits
These commands allow management session limits to be configured for specific applications.

security session limit application create
Create per-application session limit

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
This command allows creation of a per-application management session limit that does not yet exist.

Parameters
-\-interface {cli|ontapi|rest} - Interface
  The interface (CLI, ONTAPI, or REST) to which the limit applies.

-\-application <text> - Application
  The specified application to which this limit applies. The limit with the application name -default- is the limit used for any application without a specific configured limit.

-\-max-active-limit <integer> - Max-Active Limit
  The maximum number of concurrent sessions allowed for this interface and application.

Examples
The following example illustrates creating a limit for management sessions from a custom application.
security session limit application delete

Delete per-application session limit

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
This command allows deletion of a per-application management session limit.

Parameters
- **-interface** `{cli|ontapi|rest}` - Interface
  The interface (CLI, ONTAPI, or REST) to which the limit applies.
- **-application** `<text>` - Application
  The specified application to which this limit applies. The limit with the application name `-default-` is the limit used for any application without a specific configured limit.

Examples
The following example illustrates deleting a limit for management sessions from a custom application.

```
cluster1:~*> security session limit application delete -interface ontapi -application "custom_app"
```

security session limit application modify

Modify per-application session limit

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
This command allows modification of a per-application management session limit.

Parameters
- **-interface** `{cli|ontapi|rest}` - Interface
  The interface (CLI, ONTAPI, or REST) to which the limit applies.
- **-application** `<text>` - Application
  The specified application to which this limit applies. The limit with the application name `-default-` is the limit used for any application without a specific configured limit.
- **[-max-active-limit <integer>]** - Max-Active Limit
  The maximum number of concurrent sessions allowed for this interface and application.

Examples
The following example illustrates modifying management session limits for some custom applications.
security session limit application show

Show per-application session limits

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
This command shows the per-application management session limits that have been configured for each interface and application.

Parameters

{ [-fields <fieldname>, ...]
    If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

    | [-instance ]
    If you specify the -instance parameter, the command displays detailed information about all fields.

    [-interface {cli|ontapi|rest}] - Interface
    Selects the sessions that match this parameter value. This identifies the interface (CLI, ONTAPI, or REST) to which the limit applies.

    [-application <text>] - Application
    Selects the sessions that match this parameter value. This identifies the application for the limit. The limit with the application name -default- is the limit used for any application without a specific configured limit.

    [-max-active-limit <integer>] - Max-Active Limit
    Selects the sessions that match this parameter value. This identifies the configured limit that is used to throttle or reject requests.

Examples
The following example illustrates displaying the per-application limits for ONTAPI management sessions.

```
cluster1:~> security session limit application show -interface ontapi
<table>
<thead>
<tr>
<th>Interface</th>
<th>Application</th>
<th>Max-Active</th>
</tr>
</thead>
<tbody>
<tr>
<td>ontapi</td>
<td>-default-</td>
<td>5</td>
</tr>
<tr>
<td>ontapi</td>
<td>custom_app</td>
<td>10</td>
</tr>
</tbody>
</table>
2 entries were displayed.
```

Security Session Location Limit Commands

Manage per-location session limits

These commands allow management session limits to be configured for specific locations.
security session limit location create

Create per-location session limit

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
This command allows creation of a per-location management session limit that does not yet exist.

Parameters
- \texttt{interface \{cli|ontapi|rest\}} - Interface
  The interface (CLI, ONTAPI, or REST) to which the limit applies.
- \texttt{location <text> } - Location
  The specified location to which this limit applies. The limit with the location name -\texttt{default}-(in the Default IPspace) is the limit used for any location (in any IPspace) without a specific configured limit.
- \texttt{[ipspace <IPspace>]} - IPspace of Location
  This identifies the IPspace of the client location. If not specified, changes are made in the Default IPspace.
- \texttt{max-active-limit <integer>} - Max-Active Limit
  The maximum number of concurrent sessions allowed for this interface and location.

Examples
The following example illustrates creating a CLI limit for specific location.

```
cluster1::*> security session limit location create -interface cli -location 10.98.16.164 -max-active-limit 1
```

security session limit location delete

Delete per-location session limit

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
This command allows deletion of a per-location management session limit.

Parameters
- \texttt{interface \{cli|ontapi|rest\}} - Interface
  The interface (CLI, ONTAPI, or REST) to which the limit applies.
- \texttt{location <text> } - Location
  The specified location to which this limit applies. The limit with the location name -\texttt{default}-(in the Default IPspace) is the limit used for any location (in any IPspace) without a specific configured limit.
- \texttt{[ipspace <IPspace>]} - IPspace of Location
  This identifies the IPspace of the client location. If not specified, changes are made in the Default IPspace.

Examples
The following example illustrates deleting limits for management sessions from a specific set of locations.
security session limit location modify

Modify per-location session limit

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
This command allows modification of a per-location management session limit.

Parameters
- -interface (cli|ontapi|rest) - Interface
  The interface (CLI, ONTAPI, or REST) to which the limit applies.
- -location <text> - Location
  The specified location to which this limit applies. The limit with the location name -default- (in the Default IPspace) is the limit used for any location (in any IPspace) without a specific configured limit.
- [-ipspace <IPspace>] - IPspace of Location
  This identifies the IPspace of the client location. If not specified, changes are made in the Default IPspace.
- [-max-active-limit <integer>] - Max-Active Limit
  The maximum number of concurrent sessions allowed for this interface and location.

Examples
The following example illustrates modifying management sessions limits for specific locations.

cluster1::*> security session limit location modify -interface * -location 10.98.* -max-active-limit 2
3 entries were modified.

security session limit location show

Show per-location session limits

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
This command shows the per-location management session limits that have been configured for each interface and location.

Parameters
- [-fields <fieldname>, ...]
  If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use -fields ? to display the fields to specify.
- [-instance]
  If you specify the -instance parameter, the command displays detailed information about all fields.
[-interface \{cli\|ontapi\|rest\}] - Interface

Selects the sessions that match this parameter value. This identifies the interface (CLI, ONTAPI, or REST) to which the limit applies.

[-location <text>] - Location

Selects the sessions that match this parameter value. This identifies the location for the limit. The limit with the location name -default- (only in the Default IPspace) is the limit used for any location (in any IPspace) without a specific configured limit.

[-ipspace <IPspace>] - IPspace of Location

Selects the sessions that match this parameter value. This identifies the IPspace of the client location. The default IPspace is Default.

[-max-active-limit <integer>] - Max-Active Limit

Selects the sessions that match this parameter value. This identifies the configured limit that is used to throttle or reject requests.

**Examples**

The following example illustrates displaying the per-location limits for management sessions.

```
cluster1:*> security session limit location show
Interface Location             IPspace     Max-Active
--------- -------------------- ----------- ----------
cli       -default-            Default             16
cli       10.98.16.164         Default              0
ontapi    -default-            Default              6
ontapi    10.98.16.164         Default              0
4 entries were displayed.
```

**Security Session Request Limit Commands**

Manage per-request session limits

These commands allow management session limits to be configured for specific requests.

**security session limit request create**

Create per-request session limit

Availability: This command is available to cluster administrators at the advanced privilege level.

Description

This command allows creation of a per-request management session limit that does not yet exist.

Parameters

-**interface \{cli\|ontapi\|rest\}** - Interface

The interface (CLI, ONTAPI, or REST) to which the limit applies.

-**request <text>** - Request Name

The specified request to which this limit applies. The limit with the request name -default- is the limit used for any request without a specific configured limit.

-**max-active-limit <integer>** - Max-Active Limit

The maximum number of concurrent sessions allowed for this interface and request.
Examples
The following example illustrates creating a limit for number of clients executing a specific API.

```
cluster1:*> security session limit request create -interface ontapi -request storage-disk-get-iter -max-active-limit 2
```

security session limit request delete
Delete per-request session limit

**Availability:** This command is available to cluster administrators at the advanced privilege level.

**Description**
This command allows deletion of a per-request management session limit.

**Parameters**
- `interface {cli|ontapi|rest} - Interface`
  The interface (CLI, ONTAPI, or REST) to which the limit applies.
- `request <text> - Request Name`
  The specified request to which this limit applies. The limit with the request name -default- is the limit used for any request without a specific configured limit.

Examples
The following example illustrates deleting custom limits for that were configured for the volume commands and APIs.

```
cluster1:*> security session limit request delete -interface * -request volume*
4 entries were deleted.
```

security session limit request modify
Modify per-request session limit

**Availability:** This command is available to cluster administrators at the advanced privilege level.

**Description**
This command allows modification of a per-request management session limit.

**Parameters**
- `interface {cli|ontapi|rest} - Interface`
  The interface (CLI, ONTAPI, or REST) to which the limit applies.
- `request <text> - Request Name`
  The specified request to which this limit applies. The limit with the request name -default- is the limit used for any request without a specific configured limit.
- `[-max-active-limit <integer>] - Max-Active Limit`
  The maximum number of concurrent sessions allowed for this interface and request.
Examples
The following example illustrates modifying the limit of the number of clients simultaneously executing a specific API.

```
cluster1::*> security session limit request modify -interface ontapi -request storage-disk-get-iter -max-active-limit 4
```

**security session limit request show**

Show per-request session limits

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

**Description**

This command shows the per-request management session limits that have been configured for each interface and request.

**Parameters**

```
[-fields <fieldname>, ...]
```

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

```
[-instance]
```

If you specify the `-instance` parameter, the command displays detailed information about all fields.

```
[-interface {cli|ontapi|rest}] - Interface
```

Selects the sessions that match this parameter value. This identifies the interface (CLI, ONTAPI, or REST) to which the limit applies.

```
[-request <text>] - Request Name
```

Selects the sessions that match this parameter value. This identifies the request (command or API) for the limit. The limit with the request name `-default-` is the limit used for any request without a specific configured limit.

```
[-max-active-limit <integer>] - Max-Active Limit
```

Selects the sessions that match this parameter value. This identifies the configured limit that is used to throttle or reject requests.

**Examples**

The following example illustrates displaying the per-request limits for management sessions.

```
cluster1::*> security session limit request show
Interface Request                Max-Active
------------- ----------------------
cli       -default-                10
ontapi    -default-                 5
ontapi    storage-disk-get-iter    2
3 entries were displayed.
```

**Security Session User Limit Commands**

Manage per-user session limits

These commands allow management session limits to be configured for specific Vserver users.
security session limit user create

Create per-user session limit

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
This command allows creation of a per-user management session limit that does not yet exist.

Parameters
- \texttt{-interface \{cli|ontapi|rest\} - Interface}
  The interface (CLI, ONTAPI, or REST) to which the limit applies.
- \texttt{-vserver \{vserver\} - Vserver}
  The specified Vserver to which this limit applies. The "Cluster" Vserver is used to limit Vservers that do not have a configured limit.
- \texttt{-user \{text\} - User}
  The specified user to which this limit applies. The limit with the user name \texttt{-default-} is the limit used for any user without a specific configured limit.
- \texttt{-max-active-limit \{integer\} - Max-Active Limit}
  The maximum number of concurrent sessions allowed for this interface, Vserver, and user.

Examples
The following example illustrates creating a per-user limit override for ONTAPI requests for the admin user in the admin Vserver.

```
cluster1:*> security session limit user create -interface ontapi -vserver cluster1 -username admin -max-active-limit 16
```

security session limit user delete

Delete per-user session limit

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
This command allows deletion of a per-user management session limit.

Parameters
- \texttt{-interface \{cli|ontapi|rest\} - Interface}
  The interface (CLI, ONTAPI, or REST) to which the limit applies.
- \texttt{-vserver \{vserver\} - Vserver}
  The specified Vserver to which this limit applies. The "Cluster" Vserver is used to limit Vservers that do not have a configured limit.
- \texttt{-user \{text\} - User}
  The specified user to which this limit applies. The limit with the user name \texttt{-default-} is the limit used for any user without a specific configured limit.
Examples
The following example illustrates deleting all user-specific limits for CLI management sessions.

```
cluster1:*> security session limit user delete -interface cli -user !"-default-"
2 entries were deleted.
```

security session limit user modify
Modify per-user session limit

**Availability:** This command is available to cluster administrators at the advanced privilege level.

**Description**
This command allows modification of a per-user management session limit.

**Parameters**
- **-interface (cli|ontapi|rest)** - Interface
  The interface (CLI, ONTAPI, or REST) to which the limit applies.
- **-vserver <vserver>** - Vserver
  The specified Vserver to which this limit applies. The "Cluster" Vserver is used to limit Vservers that do not have a configured limit.
- **-user <text>** - User
  The specified user to which this limit applies. The limit with the user name "default" is the limit used for any user without a specific configured limit.
- **[-max-active-limit <integer>]** - Max-Active Limit
  The maximum number of concurrent sessions allowed for this interface, Vserver, and user.

Examples
The following example illustrates modifying the admin user's limit for CLI management sessions.

```
cluster1:*> security session limit user modify -interface cli -vserver cluster1 -username admin -
max-active-limit 30
```

security session limit user show
Show per-user session limits

**Availability:** This command is available to cluster administrators at the advanced privilege level.

**Description**
This command shows the per-user management session limits that have been configured for each interface, Vserver, and user.

**Parameters**

```
[-fields <fieldname>, ...]
```
If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.
If you specify the `-instance` parameter, the command displays detailed information about all fields.

```
-Interface {cli|ontapi|rest} - Interface
```

Selects the sessions that match this parameter value. This identifies the interface (CLI, ONTAPI, or REST) to which the limit applies.

```
-vserver <vserver> - Vserver
```

Selects the sessions that match this parameter value. This identifies the Vserver for the limit. The "Cluster" Vserver is used to limit Vservers that do not have a configured limit.

```
-user <text> - User
```

Selects the sessions that match this parameter value. This identifies the user for the limit. The limit with the user name `-default` is the limit used for any user without a specific configured limit.

```
-max-active-limit <integer> - Max-Active Limit
```

Selects the sessions that match this parameter value. This identifies the configured limit that is used to throttle or reject requests.

**Examples**

The following example illustrates displaying the per-user limits for CLI management sessions. In this example, there is a default limit of 4 sessions for each user. That limit is expanded to 8 for the admin Vserver. That limit is further expanded to 20 for the `admin` user in the admin Vserver.

```
cluster1::*> security session limit user show -interface cli
Interface Vserver              User                Max-Active
--------- -------------------- ------------------- ----------
cli       Cluster              -default-                    4
cli       cluster1             -default-                    8
cli       cluster1             admin                       20
3 entries were displayed.
```

**Security Session Vserver Limit Commands**

Manage per-vserver session limits

These commands allow management session limits to be configured for specific Vservers.

**security session limit vserver create**

Create per-vserver session limit

**Availability:** This command is available to `cluster` administrators at the `advanced` privilege level.

**Description**

This command allows creation of a per-Vserver management session limit that does not yet exist.

**Parameters**

```
-Interface {cli|ontapi|rest} - Interface
```

The interface (CLI, ONTAPI, or REST) to which the limit applies.

```
-vserver <vserver> - Vserver
```

The specified Vserver to which this limit applies. The "Cluster" Vserver is used to limit Vservers that do not have a configured limit.

```
-max-active-limit <integer> - Max-Active Limit
```

The maximum number of concurrent sessions allowed for this interface and Vserver.
Examples
The following example illustrates creating a per-Vserver limit override for ONTAPI requests on the admin Vserver.

```
class1:*> security session limit vserver create -interface ontapi -vserver class1 -max-active-limit 4
```

security session limit vserver delete
Delete per-vserver session limit

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

**Description**
This command allows deletion of a per-Vserver management session limit. The "Cluster" vserver is used when the specific Vserver doesn't have a configured limit.

**Parameters**
- `interface {cli|ontapi|rest} - Interface`
  The interface (CLI, ONTAPI, or REST) to which the limit applies.
- `vserver <vserver> - Vserver`
  The specified Vserver to which this limit applies. The "Cluster" Vserver is used to limit Vservers that do not have a configured limit.

Examples
The following example illustrates deleting all per-Vserver limits for management sessions except the default limit.

```
class1:*> security session limit vserver delete -interface * -vserver !Cluster
1 entries was deleted.
```

security session limit vserver modify
Modify per-vserver session limit

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

**Description**
This command allows modification of a per-Vserver management session limit.

**Parameters**
- `interface {cli|ontapi|rest} - Interface`
  The interface (CLI, ONTAPI, or REST) to which the limit applies.
- `vserver <vserver> - Vserver`
  The specified Vserver to which this limit applies. The "Cluster" Vserver is used to limit Vservers that do not have a configured limit.
- `[-max-active-limit <integer>] - Max-Active Limit`
  The maximum number of concurrent sessions allowed for this interface and Vserver.
Examples
The following example illustrates modifying the admin Vserver's limit for CLI management sessions.

cluster1:*> security session limit vserver modify -interface cli -vserver cluster1 -max-active-limit 40

security session limit vserver show
Show per-vserver session limits
Availability: This command is available to cluster administrators at the advanced privilege level.

Description
This command shows the per-Vserver management session limits that have been configured for each interface and Vserver.

Parameters
{-fields <fieldname>, ...}
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

|--instance}
If you specify the -instance parameter, the command displays detailed information about all fields.

[-interface {cli|ontapi|rest}]- Interface
Selects the sessions that match this parameter value. This identifies the interface (CLI, ONTAPI, or REST) to which the limit applies.

[-vserver <vserver>]- Vserver
Selects the sessions that match this parameter value. This identifies the Vserver for the limit. The "Cluster" Vserver is used to limit Vservers that do not have a configured limit.

[-max-active-limit <integer>]- Max-Active Limit
Selects the sessions that match this parameter value. This identifies the configured limit that is used to throttle or reject requests.

Examples
The following example illustrates displaying the per-Vserver limits for management sessions.

cluster1:*> security session limit vserver show
<table>
<thead>
<tr>
<th>Interface</th>
<th>Vserver</th>
<th>Max-Active</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Cluster</td>
<td>4</td>
</tr>
<tr>
<td>ontapi</td>
<td>Cluster</td>
<td>2</td>
</tr>
<tr>
<td>ontapi</td>
<td>cluster1</td>
<td>16</td>
</tr>
</tbody>
</table>
3 entries were displayed.

Security Session Request-Statistics Commands
View session request statistics
These commands provide historical statistics surrounding management session activity for specific categories, including application, location, request, user, and Vserver.
security session request-statistics show-by-application

Show session request statistics by application

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The security session request-statistics show-by-application command shows historical statistics for management session activity, categorized by application name. CLI sessions connections will have an application name based on the connection method, i.e.: ssh, telnet, rsh, console, or ngsh. ONTAPI sessions will extract the application name from the ZAPI request. ONTAP looks for the application name in the following three locations, in the following order of precedence:

1. The "X-Dot-Client-App" HTTP header;
2. The "app-name" attribute of the "netapp" element, within the ZAPI XML request;
3. The "User-Agent" HTTP header.

Parameters

[-fields <fieldname>, ...]
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

[-instance]
If you specify the -instance parameter, the command displays detailed information about all fields.

[-node {<nodename>|local}] - Node
Selects the sessions that match this parameter value. This identifies the node that processed the session.

[-interface {cli|ontapi|rest}] - Interface
Selects the sessions that match this parameter value. This identifies the interface (CLI, ONTAPI, or REST) that processed the session.

[-application <text>] - Application
Selects the sessions that match this parameter value. This identifies the calling application by name.

[-total <integer>] - Total Requests
Selects the sessions that match this parameter value. This identifies the total number of requests that have been made on a session. The following commands are not counted: top, up, cd, rows, history, exit.

[-blocked <integer>] - Blocked Requests
Selects the sessions that match this parameter value. This identifies the number of requests that were blocked due to configured limits.

[-failed <integer>] - Failed Requests
Selects the sessions that match this parameter value. This identifies the number of requests that failed for any reason (including if they were blocked by configured limits).

[-max-time <integer>] - Maximum Time (ms)
Selects the sessions that match this parameter value. This identifies the maximum amount of time (in milliseconds) that any request took.

[-last-time <integer>] - Last Time (ms)
Selects the sessions that match this parameter value. This identifies the amount of time (in milliseconds) that the last request took.

[-active <integer>] - Number Active Now
Selects the sessions that match this parameter value. This identifies the number of currently active sessions.
Selects the sessions that match this parameter value. When a session is active, this indicates the time (in seconds) since the last session started.

- **[-idle-seconds <integer>] - Idle Seconds**

Selects the sessions that match this parameter value. When no sessions are active, this indicates the time (in seconds) since the last session ended.

- **[-total-seconds <integer>] - Total Seconds**

Selects the sessions that match this parameter value. This identifies the total time (in seconds) that have been taken by all completed requests; it does not include session idle time.

- **[-average-time <integer>] - Average Time (ms)**

Selects the sessions that match this parameter value. This identifies the mean time spent processing requests.

- **[-success-percent <percent>] - Success Percent**

Selects the sessions that match this parameter value. This identifies the percentage of successful requests.

- **[-blocked-percent <percent>] - Blocked Percent**

Selects the sessions that match this parameter value. This identifies the percentage of requests that were blocked due to configured limits.

- **[-failed-percent <percent>] - Failed Percent**

Selects the sessions that match this parameter value. This identifies the percentage of requests that failed for any reason (including if they were blocked by configured limits).

- **[-max-active-limit <integer>] - Max-Active Limit (privilege: advanced)**

Selects the sessions that match this parameter value. This identifies the configured limit that is used to throttle or reject requests.

### Examples

The following example illustrates displaying historical statistics for all management session activity across the cluster, categorized by application name.

```
cluster1::> security session request-statistics show-by-application
```

<table>
<thead>
<tr>

The following example illustrates displaying historical statistics for management session activity on a specific node and for a specific application.
security session request-statistics show-by-location

Show session request statistics by location

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The security session request-statistics show-by-location command shows historical statistics for management session activity, categorized by client location.

Parameters

[-fields <fieldname>, ...]
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

[-instance]
If you specify the -instance parameter, the command displays detailed information about all fields.

[-node <nodename> | local] - Node
Selects the sessions that match this parameter value. This identifies the node that processed the session.

[-interface {cli|ontapi|rest}] - Interface
Selects the sessions that match this parameter value. This identifies the interface (CLI, ONTAPI, or REST) that processed the session.

[-location <text>] - Client Location
Selects the sessions that match this parameter value. This identifies the location of the calling client application. This is typically the IP address of the calling client, or "console" or "localhost" for console or localhost connections.

[-ipspace <IPspace>] - IPspace of Location
Selects the sessions that match this parameter value. This identifies the IPspace of the client location.

[-total <integer>] - Total Requests
Selects the sessions that match this parameter value. This identifies the total number of requests that have been made on a session. The following commands are not counted: top, up, cd, rows, history, exit.

[-blocked <integer>] - Blocked Requests
Selects the sessions that match this parameter value. This identifies the number of requests that were blocked due to configured limits.

[-failed <integer>] - Failed Requests
Selects the sessions that match this parameter value. This identifies the number of requests that failed for any reason (including if they were blocked by configured limits).
[-max-time <integer>] - Maximum Time (ms)
Selects the sessions that match this parameter value. This identifies the maximum amount of time (in milliseconds) that any request took.

[-last-time <integer>] - Last Time (ms)
Selects the sessions that match this parameter value. This identifies the amount of time (in milliseconds) that the last request took.

[-active <integer>] - Number Active Now
Selects the sessions that match this parameter value. This identifies the number of currently active sessions.

[-max-active <integer>] - Max Number Active
Selects the sessions that match this parameter value. This identifies the maximum number of concurrently active sessions.

[-last-active-seconds <integer>] - Seconds Since Last Session Start
Selects the sessions that match this parameter value. When a session is active, this indicates the time (in seconds) since the last session started.

[-idle-seconds <integer>] - Idle Seconds
Selects the sessions that match this parameter value. When no sessions are active, this indicates the time (in seconds) since the last session ended.

[-total-seconds <integer>] - Total Seconds
Selects the sessions that match this parameter value. This identifies the total time (in seconds) that have been taken by all completed requests; it does not include session idle time.

[-average-time <integer>] - Average Time (ms)
Selects the sessions that match this parameter value. This identifies the mean time spent processing requests.

[-success-percent <percent>] - Success Percent
Selects the sessions that match this parameter value. This identifies the percentage of successful requests.

[-blocked-percent <percent>] - Blocked Percent
Selects the sessions that match this parameter value. This identifies the percentage of requests that were blocked due to configured limits.

[-failed-percent <percent>] - Failed Percent
Selects the sessions that match this parameter value. This identifies the percentage of requests that failed for any reason (including if they were blocked by configured limits).

[-max-active-limit <integer>] - Max-Active Limit (privilege: advanced)
Selects the sessions that match this parameter value. This identifies the configured limit that is used to throttle or reject requests.

Examples
The following example illustrates displaying historical statistics for all management session activity across the cluster, categorized by location.

```
cluster1::> security session request-statistics show-by-location

Node: node1               Interface: cli                 Idle    Total
Location          IPspace    Total Now Max Pass Fail  Seconds  Seconds Avg (ms)
----------------- ------- -------- --- --- ---- ---- -------- -------- --------
console           Default       21   1   1 100%    0        -      127     6063
localhost         Default     2523   0   5  95%  115       20      280      111

Node: node1               Interface: ontapi              Idle    Total
Location          IPspace    Total Now Max Pass Fail  Seconds  Seconds Avg (ms)
----------------- ------- -------- --- --- ---- ---- -------- -------- --------
10.98.17.254      Default        2   0   1 100%    0        -     2419     18
```

**security session request-statistics show-by-request**

Show session request statistics by request name

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**

The security session request-statistics show-by-request command shows historical statistics for management session activity, categorized by request (command or API name).

**Parameters**

```
[-fields <fieldname>, ...]
```

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

```
[-instance]
```

If you specify the `-instance` parameter, the command displays detailed information about all fields.

```
[-node <nodename>|local] - Node
```

Selects the sessions that match this parameter value. This identifies the node that processed the session.

```
[-interface {cli|ontapi|rest}] - Interface
```

Selects the sessions that match this parameter value. This identifies the interface (CLI, ONTAPI, or REST) that processed the session.

```
[-request <text>] - Request Name
```

Selects the sessions that match this parameter value. This identifies the command associated with these requests.

```
[-total <integer>] - Total Requests
```

Selects the sessions that match this parameter value. This identifies the total number of requests that have been made on a session. The following commands are not counted: top, up, cd, rows, history, exit.

```
[-blocked <integer>] - Blocked Requests
```

Selects the sessions that match this parameter value. This identifies the number of requests that were blocked due to configured limits.
[-failed <integer>] - Failed Requests
Selects the sessions that match this parameter value. This identifies the number of requests that failed for any reason (including if they were blocked by configured limits).

[-max-time <integer>] - Maximum Time (ms)
Selects the sessions that match this parameter value. This identifies the maximum amount of time (in milliseconds) that any request took.

[-last-time <integer>] - Last Time (ms)
Selects the sessions that match this parameter value. This identifies the amount of time (in milliseconds) that the last request took.

[-active <integer>] - Number Active Now
Selects the sessions that match this parameter value. This identifies the number of currently active requests.

[-max-active <integer>] - Max Number Active
Selects the sessions that match this parameter value. This identifies the maximum number of concurrently active requests.

[-last-active-seconds <integer>] - Seconds Since Last Request Start
Selects the sessions that match this parameter value. When requests are active, this indicates the time (in seconds) since the last request started.

[-idle-seconds <integer>] - Idle Seconds
Selects the sessions that match this parameter value. When no requests are active, this indicates the time (in seconds) since the last request ended.

[-total-seconds <integer>] - Total Seconds
Selects the sessions that match this parameter value. This identifies the total time (in seconds) that have been taken by all completed requests; it does not include session idle time.

[-average-time <integer>] - Average Time (ms)
Selects the sessions that match this parameter value. This identifies the mean time spent processing requests.

[-success-percent <percent>] - Success Percent
Selects the sessions that match this parameter value. This identifies the percentage of successful requests.

[-blocked-percent <percent>] - Blocked Percent
Selects the sessions that match this parameter value. This identifies the percentage of requests that were blocked due to configured limits.

[-failed-percent <percent>] - Failed Percent
Selects the sessions that match this parameter value. This identifies the percentage of requests that failed for any reason (including if they were blocked by configured limits).

[-max-active-limit <integer>] - Max-Active Limit (privilege: advanced)
Selects the sessions that match this parameter value. This identifies the configured limit that is used to throttle or reject requests.

Examples
The following example illustrates displaying historical statistics for all management session activity on a specific node, with a specific request query.

```
cluster1::> security session request-statistics show-by-request -node node1 -request network*
```

<table>

security session request-statistics show-by-user

Show session request statistics by username

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**
The `security session request-statistics show-by-user` command shows historical statistics for management session activity, categorized by username. Entries for username 'autosupport' reflect commands that are executed by the AutoSupport OnDemand feature.

**Parameters**

```
[-fields <fieldname>, ...]
```
If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

```
[-instance]
```
If you specify the `-instance` parameter, the command displays detailed information about all fields.

```
[-node <nodename> [local]] - Node
```
Selects the sessions that match this parameter value. This identifies the node that processed the session.

```
[-interface {cli|ontapi|rest}] - Interface
```
Selects the sessions that match this parameter value. This identifies the interface (CLI, ONTAPI, or REST) that processed the session.

```
[-vserver <vserver>] - Vserver
```
Selects the sessions that match this parameter value. This identifies the Vserver associated with this management session.

```
[-username <text>] - Username
```
Selects the sessions that match this parameter value. This identifies the authenticated user associated with this management session.

```
[-total <integer>] - Total Requests
```
Selects the sessions that match this parameter value. This identifies the total number of requests that have been made on a session. The following commands are not counted: top, up, cd, rows, history, exit.

```
[-blocked <integer>] - Blocked Requests
```
Selects the sessions that match this parameter value. This identifies the number of requests that were blocked due to configured limits.

```
[-failed <integer>] - Failed Requests
```
Selects the sessions that match this parameter value. This identifies the number of requests that failed for any reason (including if they were blocked by configured limits).

```
[-max-time <integer>] - Maximum Time (ms)
```
Selects the sessions that match this parameter value. This identifies the maximum amount of time (in milliseconds) that any request took.
[-last-time <integer>] - Last Time (ms)
Selects the sessions that match this parameter value. This identifies the amount of time (in milliseconds) that
the last request took.

[-active <integer>] - Number Active Now
Selects the sessions that match this parameter value. This identifies the number of currently active sessions.

[-max-active <integer>] - Max Number Active
Selects the sessions that match this parameter value. This identifies the maximum number of concurrently
active sessions.

[-last-active-seconds <integer>] - Seconds Since Last Session Start
Selects the sessions that match this parameter value. When a session is active, this indicates the time (in
seconds) since the last session started.

[-idle-seconds <integer>] - Idle Seconds
Selects the sessions that match this parameter value. When no sessions are active, this indicates the time (in
seconds) since the last session ended.

[-total-seconds <integer>] - Total Seconds
Selects the sessions that match this parameter value. This identifies the total time (in seconds) that have been
taken by all completed requests; it does not include session idle time.

[-average-time <integer>] - Average Time (ms)
Selects the sessions that match this parameter value. This identifies the mean time spent processing requests.

[-success-percent <percent>] - Success Percent
Selects the sessions that match this parameter value. This identifies the percentage of successful requests.

[-blocked-percent <percent>] - Blocked Percent
Selects the sessions that match this parameter value. This identifies the percentage of requests that were
blocked due to configured limits.

[-failed-percent <percent>] - Failed Percent
Selects the sessions that match this parameter value. This identifies the percentage of requests that failed for
any reason (including if they were blocked by configured limits).

[-max-active-limit <integer>] - Max-Active Limit (privilege: advanced)
Selects the sessions that match this parameter value. This identifies the configured limit that is used to throttle
or reject requests.

Examples
The following example illustrates displaying historical statistics for all management session activity across the cluster,
categorized by username.

```
cluster1::> security session request-statistics show-by-user
Node: node1               Interface: cli                 Idle    Total

security session request-statistics show-by-vserver

Show session request statistics by Vserver

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**
The `security session request-statistics show-by-vserver` command shows historical statistics for management session activity, categorized by vserver.

**Parameters**

```
[-fields <fieldname>, ...]  
   If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

[-instance]  
   If you specify the -instance parameter, the command displays detailed information about all fields.

[-node {<nodename>|local}] - Node  
   Selects the sessions that match this parameter value. This identifies the node that processed the session.

[-interface {cli|ontapi|rest}] - Interface  
   Selects the sessions that match this parameter value. This identifies the interface (CLI, ONTAPI, or REST) that processed the session.

[-vserver <vserver>] - Vserver  
   Selects the sessions that match this parameter value. This identifies the Vserver associated with this management session.

[-total <integer>] - Total Requests  
   Selects the sessions that match this parameter value. This identifies the total number of requests that have been made on a session. The following commands are not counted: top, up, cd, rows, history, exit.

[-blocked <integer>] - Blocked Requests  
   Selects the sessions that match this parameter value. This identifies the number of requests that were blocked due to configured limits.

[-failed <integer>] - Failed Requests  
   Selects the sessions that match this parameter value. This identifies the number of requests that failed for any reason (including if they were blocked by configured limits).```
[-max-time <integer>] - Maximum Time (ms)
Selects the sessions that match this parameter value. This identifies the maximum amount of time (in milliseconds) that any request took.

[-last-time <integer>] - Last Time (ms)
Selects the sessions that match this parameter value. This identifies the amount of time (in milliseconds) that the last request took.

[-active <integer>] - Number Active Now
Selects the sessions that match this parameter value. This identifies the number of currently active sessions.

[-max-active <integer>] - Max Number Active
Selects the sessions that match this parameter value. This identifies the maximum number of concurrently active sessions.

[-last-active-seconds <integer>] - Seconds Since Last Session Start
Selects the sessions that match this parameter value. When a session is active, this indicates the time (in seconds) since the last session started.

[-idle-seconds <integer>] - Idle Seconds
Selects the sessions that match this parameter value. When no sessions are active, this indicates the time (in seconds) since the last session ended.

[-total-seconds <integer>] - Total Seconds
Selects the sessions that match this parameter value. This identifies the total time (in seconds) that have been taken by all completed requests; it does not include session idle time.

[-average-time <integer>] - Average Time (ms)
Selects the sessions that match this parameter value. This identifies the mean time spent processing requests.

[-success-percent <percent>] - Success Percent
Selects the sessions that match this parameter value. This identifies the percentage of successful requests.

[-blocked-percent <percent>] - Blocked Percent
Selects the sessions that match this parameter value. This identifies the percentage of requests that were blocked due to configured limits.

[-failed-percent <percent>] - Failed Percent
Selects the sessions that match this parameter value. This identifies the percentage of requests that failed for any reason (including if they were blocked by configured limits).

[-max-active-limit <integer>] - Max-Active Limit (privilege: advanced)
Selects the sessions that match this parameter value. This identifies the configured limit that is used to throttle or reject requests.

**Examples**

The following example illustrates displaying historical statistics for all management session activity across the cluster, categorized by Vserver.

```
cluster1::> security session request-statistics show-by-vserver
Node: node1 | Interface: cli
Vserver | Total Now Max Pass Fail | Idle Seconds | Total Seconds Avg (ms)
------------------------ | --------------- | ------------- | ----------------------
cluster1 | 2725 1 8 94% 146 | - | 3052 1120

Node: node1 | Interface: ontapi
Vserver | Total Now Max Pass Fail | Idle Seconds | Total Seconds Avg (ms)
------------------------ | --------------- | ------------- | ----------------------
cluster1 | 2 0 1 100% 0 | 2742 | 0 18
```

Security Session Commands
The following example illustrates displaying historical statistics for management session activity on a specific node, for a specific Vserver.

```
cluster1::> security session request-statistics show-by-vserver -node node1 -vserver cluster1
```

```
Node: node1               Interface: cli                 Idle    Total
Vserver                      Total Now Max Pass Fail  Seconds Avg (ms)

**security ssh commands**

Manage SSH Configuration

**security ssh add**

Add SSH configuration options

**Availability:** This command is available to `cluster` and `Vserver` administrators at the `admin` privilege level.

**Description**

The `security ssh add` command adds additional SSH key exchange algorithms or ciphers or MAC algorithms to the existing configurations of the cluster or a Vserver. The added algorithms or ciphers or MAC algorithms are enabled on the cluster or Vserver. If you change the cluster configuration settings, it is used as the default for all newly created Vservers. The existing SSH key exchange algorithms, ciphers, and MAC algorithms remain unchanged in the configuration. If the SSH key exchange algorithms or ciphers or MAC algorithms are already enabled in the current configuration, the command will not fail. Data ONTAP supports the `diffie-hellman-group-exchange-sha256` key exchange algorithm for SHA-2. Data ONTAP also supports the `diffie-hellman-group-exchange-shal`, `diffie-hellman-group14-shal`, and `diffie-hellman-group1-shal` SSH key exchange algorithms for SHA-1. The SHA-2 key exchange algorithm is more secure than the SHA-1 key exchange algorithms. Data ONTAP also supports the `ecdh-sha2-nistp256`, `ecdh-sha2-nistp384`, `ecdh-sha2-nistp521`, and `curve25519-sha256`. Data ONTAP also supports the AES and 3DES symmetric encryptions (also known as ciphers) of the following types: `aes256-ctr`, `aes192-ctr`, `aes128-ctr`, `aes256-cbc`, `aes192-cbc`, `aes128-cbc`, `aes128-gcm`, `aes256-gcm`, and `3des-cbc`. Data ONTAP supports MAC algorithms of the following types: `hmac-shal`, `hmac-shal-96`, `hmac-md5`, `hmac-md5-96`, `hmac-ripemd160`, `umac-64`, `umac-64`, `umac-128`, `hmac-sha2-256`, `hmac-sha2-512`, `hmac-shal-etm`, `hmac-shal-96-etm`, `hmac-sha2-256-etm`, `hmac-sha2-512-etm`, `hmac-md5-etm`, `hmac-md5-96-etm`, `hmac-ripemd160-etm`, `umac-64-etm`, and `umac-128-etm`.

**Parameters**

```
-vserver <Vserver Name> - Vserver
```

Identifies the Vserver to which you want to add additional SSH key exchange algorithms or ciphers.
[-key-exchange-algorithms <algorithm name>, ...] - List of SSH Key Exchange Algorithms to Add

Adds the specified SSH key exchange algorithm or algorithms to the Vserver.

[-ciphers <cipher name>, ...] - List of SSH Ciphers to Add

Adds the specified cipher or ciphers to the Vserver.

[-mac-algorithms <MAC name>, ...] - List of SSH MAC Algorithms to Add

Adds the specified MAC algorithm or algorithms to the Vserver.

Examples

The following command adds the diffie-hellman-group-exchange-sha256 and diffie-hellman-group-exchange-sha1 key exchange algorithms for the cluster1 Vserver. It also adds the aes256-cbc and aes192-cbc ciphers and the hmac-shal and hmac-sha2-256 MAC algorithms to the cluster1 Vserver.

```
cluster1::> security ssh add -vserver cluster1 -key-exchange-algorithms diffie-hellman-group-exchange-sha256,diffie-hellman-group-exchange-sha1 -ciphers aes256-cbc,aes192-cbc -mac-algorithms hmac-shal,hmac-sha2-256
```

security ssh modify

Modify SSH configuration options

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description

The security ssh modify command replaces the existing configurations of the SSH key exchange algorithms or ciphers or MAC algorithms for the cluster or a Vserver with the configuration settings you specify. If you modify the cluster configuration settings, it will be used as the default for all newly created Vservers. Data ONTAP supports the diffie-hellman-group-exchange-sha256 key exchange algorithm for SHA-2. Data ONTAP also supports the diffie-hellman-group-exchange-sha1, diffie-hellman-group14-sha1, and diffie-hellman-group1-sha1 SSH key exchange algorithms for SHA-1. The SHA-2 key exchange algorithm is more secure than the SHA-1 key exchange algorithms. Data ONTAP also supports the AES and 3DES symmetric encryptions (also known as ciphers) of the following types: aes256-ctr, aes192-ctr, aes128-ctr, aes256-cbc, aes192-cbc, aes128-cbc, aes128-gcm, aes256-gcm, and 3des-cbc. Data ONTAP supports MAC algorithms of the following types: hmac-shal, hmac-shal-96, hmac-md5, hmac-md5-96, hmac-ripemd160, umac-64, umac-64, umac-128, hmac-sha2-256, hmac-sha2-512, hmac-shal-etm, hmac-shal-96-etm, hmac-sha2-256-etm, hmac-sha2-512-etm, hmac-md5-etm, hmac-md5-96-etm, hmac-ripemd160-etm, umac-64-etm, and umac-128-etm.

Parameters

-vserver <Vserver Name> - Vserver

Identifies the Vserver for which you want to replace the existing SSH key exchange algorithm and cipher configurations.

[-key-exchange-algorithms <algorithm name>, ...] - Key Exchange Algorithms

Enables the specified SSH key exchange algorithm or algorithms for the Vserver. This parameter also replaces all existing SSH key exchange algorithms with the specified settings.

[-ciphers <cipher name>, ...] - Ciphers

Enables the specified cipher or ciphers for the Vserver. This parameter also replaces all existing ciphers with the specified settings.

[-mac-algorithms <MAC name>, ...] - MAC Algorithms

Enables the specified MAC algorithm or algorithms for the Vserver. This parameter also replaces all existing MAC algorithms with the specified settings.
[-max-authentication-retry-count <integer>] - Max Authentication Retry Count

Modifies the maximum number of authentication retry count for the Vserver.

**Examples**

The following command enables the `diffie-hellman-group-exchange-sha256` and `diffie-hellman-group14-sha1` key exchange algorithms for the cluster1 Vserver. It also enables the `aes256-ctr`, `aes192-ctr` and `aes128-ctr` ciphers, `hmac-sha1` and `hmac-sha2-256` MAC algorithms for the cluster1 Vserver. It also modifies the maximum authentication retry count to 3 for the cluster1 Vserver:

```
cluster1::> security ssh modify -vserver cluster1 -key-exchange-algorithms diffie-hellman-group-exchange-sha256,diffie-hellman-group14-sha1 -ciphers aes256-ctr,aes192-ctr,aes128-ctr -mac-algorithms hmac-sha1,hmac-sha2-256 -max-authentication-retry-count 3
```

**security ssh prepare-to-downgrade**

Downgrade the SSH configuration to be compatible with releases earlier than Data ONTAP 9.2.0.

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

**Description**

This command downgrades the SSH configurations of all Vservers and the cluster to settings compatible with releases earlier than Data ONTAP 9.2.0. This command also disables the max-authentication-retry feature. You must run this command in advanced privilege mode when prompted to do so during the release downgrade. Otherwise, the release downgrade process will fail.

**Examples**

The following command downgrades the SSH security configurations of all Vservers and the cluster to settings compatible with releases earlier than Data ONTAP 9.2.0.

```
cluster1::*> security ssh prepare-to-downgrade
```

**security ssh remove**

Remove SSH configuration options

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

**Description**

The `security ssh remove` command removes the specified SSH key exchange algorithms or ciphers from the existing configurations of the cluster or a Vserver. The removed algorithms or ciphers are disabled on the cluster or Vserver. If you changed the cluster configuration settings, it will be used as the default for all newly created Vservers. If the SSH key exchange algorithms or ciphers that you specify with this command are not currently enabled, the command will not fail. Data ONTAP supports the `diffie-hellman-group-exchange-sha256` key exchange algorithm for SHA-2. Data ONTAP also supports the `diffie-hellman-group-exchange-sha1`, `diffie-hellman-group14-sha1`, and `diffie-hellman-group1-sha1` key exchange algorithms for SHA-1. The SHA-2 key exchange algorithm is more secure than the SHA-1 key exchange algorithms. Data ONTAP also supports `ecdh-sha2-nistp256`, `ecdh-sha2-nistp384`, `ecdh-sha2-nistp521`, and `curve25519-sha256`. Data ONTAP also supports the AES and 3DES symmetric encryption (also known as ciphers) of the following types: `aes256-ctr`, `aes192-ctr`, `aes128-ctr`, `aes256-cbc`, `aes192-cbc`, `aes128-cbc`, `aes128-gcm`, `aes256-gcm` and `3des-cbc`. Data ONTAP supports MAC algorithms of the following types: `hmac-sha1`, `hmac-sha1-96`, `hmac-md5`, `hmac-md5-96`, `hmac-ripemd160`, `umac-64`, `umac-64`, `umac-128`, `hmac-sha2-256`, `hmac-sha2-512`, `hmac-sha1-128`, `hmac-sha1-96`, `hmac-sha2-256-128`, `hmac-sha2-256-96`, `hmac-sha2-512-128`, `hmac-sha2-512-96`, `hmac-ripemd160`, `umac-64`, `umac-128`, and `umac-128-128`. 
Parameters
-vserver <Vserver Name> - Vserver

Identifies the Vserver from which you want to remove the SSH key exchange algorithms or ciphers.

[-key-exchange-algorithms <algorithm name>,...] - List of SSH Key Exchange Algorithms to Remove

Removes the specified key exchange algorithm or algorithms from the Vserver.

[-ciphers <cipher name>,...] - List of SSH Ciphers to Remove

Removes the specified cipher or ciphers from the Vserver.

[-mac-algorithms <MAC name>,...] - List of SSH MAC algorithms to Remove

Removes the specified MAC algorithm or algorithms from the Vserver.

Examples
The following command removes the diffie-hellman-group1-sha1 and diffie-hellman-group-exchange-sha1 key exchange algorithms from the cluster1 Vserver. It also removes the aes128-cbc and 3des-cbc ciphers and the hmac-sha1-96 and hmac-sha2-256 MAC algorithms from the cluster1 Vserver.

```
cluster1::> security ssh remove -vserver cluster1 -key-exchange-algorithms diffie-hellman-group1-sha1,diffie-hellman-group-exchange-sha1 -ciphers aes128-cbc,3des-cbc -mac-algorithms hmac-sha1-96,hmac-sha2-256
```

security ssh show

Display SSH configuration options

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The security ssh show command displays the configurations of the SSH key exchange algorithms, ciphers, MAC algorithms and maximum authentication retry count for the cluster and Vservers. The SSH protocol uses a Diffie-Hellman based key exchange method to establish a shared secret key during the SSH negotiation phrase. The key exchange method specifies how one-time session keys are generated for encryption and authentication and how the server authentication takes place. Data ONTAP supports the diffie-hellman-group-exchange-sha256 key exchange algorithm for SHA-2. Data ONTAP also supports the diffie-hellman-group-exchange-sha1, diffie-hellman-group14-sha1, and diffie-hellman-group1-sha1 key exchange algorithms for SHA-1. Data ONTAP also supports the ecdh-sha2-nistp256, ecdh-sha2-nistp384, ecdh-sha2-nistp521, curve25519-sha256. Data ONTAP also supports the AES and 3DES symmetric encryptions (also known as ciphers) of the following types: aes256-ctr, aes192-ctr, aes128-ctr, aes256-cbc, aes192-cbc, aes128-cbc, aes128-gcm, aes256-gcm and 3des-cbc. Data ONTAP supports MAC algorithms of the following types: hmac-shal, hmac-shal-96, hmac-md5, hmac-md5-96, hmac-ripemd160, umac-64, umac-64, umac-128, hmac-sha2-256, hmac-sha2-512, hmac-sha2-etm, hmac-sha2-96-etm, hmac-sha2-256-etm, hmac-sha2-512-etm, hmac-md5-etm, hmac-md5-96-etm, hmac-ripemd160-etm, umac-64-etm, umac-128-etm

Parameters

[-fields <fieldname>,...]

If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

[-instance ]

If you specify the -instance parameter, the command displays detailed information about all fields.

[-vserver <Vserver Name>] - Vserver

Identifies the Vserver for which you want to display the SSH key exchange algorithm, cipher, and MAC algorithm configurations.
[-key-exchange-algorithms <algorithm name>, ...] - Key Exchange Algorithms
Displays the Vserver or Vservers that have the specified key exchange algorithms enabled.

[-ciphers <cipher name>, ...] - Ciphers
Displays the Vserver or Vservers that have the specified ciphers enabled.

[-mac-algorithms <MAC name>, ...] - MAC Algorithms
Displays the Vserver or Vservers that have the specified MAC algorithm or algorithms.

[-max-authentication-retry-count <integer>] - Max Authentication Retry Count
Displays Vservers with a matching maximum authentication retry count value.

### Examples
The following command displays the enabled SSH key exchange algorithms, ciphers, MAC algorithms and maximum number of authentication retry count for the cluster and all Vservers. The cluster settings are used as the default for all newly created Vservers:

```
category-1::> security ssh show
```

<table>
<thead>
<tr>
<th>Vserver</th>
<th>Ciphers</th>
<th>Key Exchange Algorithms</th>
<th>MAC Algorithms</th>
<th>Max Authentication Retry Count</th>
</tr>
</thead>
<tbody>
<tr>
<td>cluster-1</td>
<td>3des-cbc</td>
<td>diffie-hellman-group-exchange-sha256</td>
<td>hmac-sha1</td>
<td>4</td>
</tr>
</tbody>
</table>

2 entries were displayed.

### Virtual Server SSL Management
Manage the SSL configurations for a Vserver

These commands control the use of encrypted HTTP on Vservers, including whether SSL is available, which certificate is used for communication, and whether OCSP checks are enabled.

**security ssl modify**
Modify the SSL configuration for HTTP servers

**Availability:** This command is available to `cluster` and `Vserver` administrators at the `admin` privilege level.
Description
This command modifies the configuration of encrypted HTTP (SSL) for Vservers in the cluster. Depending on the requirements of the individual node's or cluster's web services (displayed by the vserver services web show command), this encryption might or might not be used. If the Vserver does not have a certificate associated with it, SSL will not be available.

Parameters
-vserver <Vserver Name> - Vserver
Identifies a Vserver for hosting SSL-encrypted web services.

[-ca <text>] - Server Certificate Issuing CA
Identifies a Certificate Authority (CA) of a certificate to be associated with the instance of a given Vserver. If this parameter, along with serial, is omitted during modification, a self-signed SSL certificate can be optionally generated for that Vserver.

[-serial <text>] - Server Certificate Serial Number
Identifies a serial number of a certificate to be associated with the instance of a given Vserver. If this parameter, along with ca, is omitted during modification, a self-signed SSL certificate can be optionally generated for that Vserver.

[-common-name <FQDN or Custom Common Name>] - Server Certificate Common Name
Identifies the common name (CN) of a certificate to be associated with the instance of a given Vserver. This parameter becomes optional if serial and ca are specified. You can use the security certificate create and security certificate install commands to add new certificates to Vservers.

Note: The use of self-signed SSL certificates exposes users to man-in-the-middle security attacks. Where possible, obtain a certificate that is signed by a reputable certificate authority (CA) and use the security certificate install command to configure it before enabling SSL on a Vserver.

[-server-enabled {true|false}] - SSL Server Authentication Enabled
Defines the working condition of SSL server authentication in an instance of the Vserver. Any Vserver with a valid certificate of type server is server-enabled.

[-client-enabled {true|false}] - SSL Client Authentication Enabled
Defines the working condition of SSL client authentication in an instance of the Vserver. Any Vserver with a valid certificate of type client-ca is client-enabled. It can only be enabled if server-enabled is true.

[-ocsp-enabled {true|false}] - Online Certificate Status Protocol Validation Enabled
This parameter enables OCSP validation of the client certificate chain. When this parameter is enabled, certificates in the certificate chain of the client will be validated against an OCSP responder after normal verification (including CRL checks) has occurred. The OCSP responder used for validation process is either extracted from the certificate itself, or it is derived by configuration.

[-ocsp-default-responder <text>] - URI of the Default Responder for OCSP Validation
This parameter sets the default OCSP responder to use. If this parameter is not enabled, the URI given will be used only if no responder URI is specified in the certificate that are being verified.

[-ocsp-override-responder {true|false}] - Force the Use of the Default Responder URI for OCSP Validation
This parameter forces the configured default OCSP responder to be used during OCSP certificate validation, even if the certificate that is being validated references an OCSP responder.

[-ocsp-responder-timeout <![<integer>h][<integer>m][<integer>s]>] - Timeout for OCSP Queries
Use this parameter to specify the timeout in seconds for OCSP responders. Specify zero for the minimum possible timeout. The default value is 10 seconds.
[-ocsp-max-response-age <unsigned32_or_unlimited>] - Maximum Allowable Age for OCSP Responses (secs)

This parameter sets the maximum allowable age (freshness) in seconds for the OCSP responses. The default value for this parameter is unlimited, which does not enforce a maximum age and the OCSP responses are considered valid as long as their expiration date field is in the future.

[-ocsp-max-response-time-skew <[<integer>h][<integer>m][<integer>s]>] - Maximum Allowable Time Skew for OCSP Response Validation

This parameter sets the maximum allowable time difference for OCSP responses (when validating their ThisUpdate and NextUpdate fields).

[-ocsp-use-request-nonce {true|false}] - Use a NONCE within OCSP Queries

This parameter determines whether the queries to the OCSP responders should contain a NONCE or not. By default, a query NONCE is always used and checked against the OCSP response. When the responder does not use NONCEs, this parameter should be disabled.

**Note:** A NONCE is a unique identifier included in each OCSP request or OCSP response to prevent a replay attack.

### Examples

The following example enables SSL server authentication for a Vserver named vs0 with a certificate that has ca as www.example.com and serial as 4F4EB629.

```bash
cluster1::> security ssl modify -vserver vs0 -ca www.example.com -serial 4F4EB629 -server-enabled true
```

The following example disables SSL server authentication for a Vserver name vs0.

```bash
cluster1::> security ssl modify -vserver vs0 -server-enabled false
```

The following example enables SSL client authentication for a Vserver named vs0.

```bash
cluster1::> security ssl modify -vserver vs0 -client-enabled true
```

The following example disables SSL client authentication for a Vserver named vs0.

```bash
cluster1::> security ssl modify -vserver vs0 -client-enabled false
```

### security ssl show

Display the SSL configuration for HTTP servers

**Availability:** This command is available to cluster and Vserver administrators at the `admin` privilege level.

**Description**

This command displays the configuration of encrypted HTTP (SSL) for Vservers in the cluster. Depending on the requirements of the individual node's or cluster's web services (displayed by the `vserver services web show` command), this encryption might or might not be used. If the Vserver does not have a certificate associated with it, SSL will not be available.
Parameters

{[-fields <fieldname>, ...]}

If you specify the `--fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `--fields ?` to display the fields to specify.

|--ocsp

If you specify the `--ocsp` parameter, the command displays the Online Certificate Status Protocol configuration.

|--instance

If you specify the `--instance` parameter, the command displays detailed information about all fields.

|vserver <Vserver Name>|- Vserver

Identifies a Vserver for hosting SSL-encrypted web services.

|ca <text>|- Server Certificate Issuing CA

Filters the display of SSL configuration by specifying the Certificate Authority (CA) that issued the server certificate.

|serial <text>|- Server Certificate Serial Number

Filters the display of SSL configuration by specifying the serial number of a server certificate.

|common-name <FQDN or Custom Common Name>|- Server Certificate Common Name

Filters the display of SSL configuration by specifying the common name for the server certificate.

|server-enabled {true|false}|- SSL Server Authentication Enabled

Filters the display of SSL configuration according to whether the SSL server authentication is enabled or disabled. Vservers have self-signed certificates automatically generated during their creation. These Vserver self-signed certificates are server-enabled by default.

|client-enabled {true|false}|- SSL Client Authentication Enabled

Filters the display of SSL configuration according to whether the SSL client authentication is enabled or disabled. You can enable client authentication only when server authentication is enabled.

|ocsp-enabled {true|false}|- Online Certificate Status Protocol Validation Enabled

Filters the display of SSL configuration when the Online Certificate Status Protocol validation is enabled.

|ocsp-default-responder <text>|- URI of the Default Responder for OCSP Validation

Filters the display of SSL configuration according to the URI of the default responder for OCSP validation.

|ocsp-override-responder {true|false}|- Force the Use of the Default Responder URI for OCSP Validation

Filters the display of SSL configuration, which forces the use of the default responder URI for OCSP validation.

|ocsp-responder-timeout <[<integer>h] [<integer>m] [<integer>s]>|- Timeout for OCSP Queries

Filters the display of SSL configuration according to the timeout for queries to OCSP responders.

|ocsp-max-response-age <unsigned32_or_unlimited>|- Maximum Allowable Age for OCSP Responses (secs)

Filters the display of SSL configuration according to the maximum allowable age (freshness) in seconds for the OCSP responses.

|ocsp-max-response-time-skew <[<integer>h] [<integer>m] [<integer>s]>|- Maximum Allowable Time Skew for OCSP Response Validation

Filters the display of SSL configuration according to the maximum allowable time difference for OCSP responses (when validating their ThisUpdate and NextUpdate fields).

|ocsp-use-request-nonce {true|false}|- Use a NONCE within OCSP Queries

Filters the display of SSL configuration by specifying whether the queries to the OCSP responders should contain a NONCE or not.
**Note:** A NONCE is a unique identifier included in each OCSP request or OCSP response to prevent a replay attack.

### Examples
The following example displays the configured certificates for Vservers.

```plaintext
cluster1::security ssl> show

Serial                          Server  Client
Vserver   Number   Common Name                             Enabled   Enabled
--------- ------ ------------------------------- ------- -------
cluster1  516C3CB3   cluster1.company.com                    true    true
vs0       516816D4   vs0.company.com                              true    false
2 entries were displayed.
```

## SnapLock Commands

Manages SnapLock attributes in the system.

The `snaplock` commands manage compliance-related functionality in the system. A volume created using the `volume create` command becomes a SnapLock volume when it is created on a SnapLock aggregate. A SnapLock aggregate is created using the `storage aggr create` command when the `snaplock-type` is specified as either `compliance` or `enterprise`.

The `snaplock compliance-clock` command can be used to manage the ComplianceClock in the system.

The `snaplock log` command can be used to manage SnapLock log infrastructure.

### snaplock legal-hold commands

Snaplock legal-hold related commands

### snaplock legal-hold abort

Abort Snaplock legal-hold operation.

**Availability:** This command is available to `cluster` and `Vserver` administrators at the `admin` privilege level.

**Description**
The `snaplock legal-hold abort` is used to abort an ongoing legal-hold operation. The type of legal-hold operations that can be aborted using this command are begin, end and dump-files. This command only aborts operations that have not yet completed. Only a user with security login role `vsadmin-snaplock` is allowed to perform this operation.
Parameters

-vserver <vserver name> - Vserver Name
   Specifies the vserver on which the legal-hold operation is running.

-operation-id <integer> - Operation ID
   Specifies the operation ID of the legal-hold operation to be aborted.

Examples

The following example aborts an ongoing legal-hold operation with operation-id 16842754:

```bash
vsl::> snaplock legal-hold abort -operation-id 16842754
vsl::>
```

snaplock legal-hold begin

Starts an operation to place files under legal-hold in the user specified path on a SnapLock compliance volume.

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description

The snaplock legal-hold begin command is used to place specified file or files under legal-hold for a given litigation. Only a user with security login role vsadmin-snaplock is allowed to perform this operation.

Parameters

-vserver <vserver name> - Vserver Name
   Specifies the name of the Vserver which owns the volume. The specified file or files to be placed under legal-hold reside on this volume.

-litigation-name <text> - Litigation Name
   Specifies the name of the litigation for which the file or files have to be placed under legal-hold.

-volume <volume name> - Volume
   Specifies the name of the SnapLock compliance volume on which the file or files to be placed under legal-hold reside.

-path <text> - Path
   Specifies a path relative to the volume root. The path can be either a file path of the single file to be placed under legal-hold or a directory path where all regular files under it must be placed under legal-hold.

Examples

The following example starts a legal-hold begin operation on file file1 in volume slc_vol1:

```bash
vsl::> snaplock legal-hold begin -litigation-name litigation1 -volume slc_vol1 -path /file1
SnapLock legal-hold begin operation is queued. Run "snaplock legal-hold show -operation-id 16842773 -instance" to view the operation status.
```

The following example starts a legal-hold begin operation on all files in the volume slc_vol1:
**snaplock legal-hold dump-files**

Dump list of files under legal-hold to specified output path.

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

**Description**
The `snaplock legal-hold dump-files` is used to dump the list of files under legal-hold for a given vserver, volume and litigation to an auto-generated file in the user specified path. Only a user with security login role `vsadmin-snaplock` is allowed to perform this operation.

**Parameters**

- `-vserver <vserver name>` - Vserver Name
  Specifies the name of the Vserver for which the list of files under legal-hold is to be dumped.

- `-litigation-name <text>` - Litigation Name
  Specifies the name of the litigation for which the list of files under legal-hold is to be dumped.

- `-volume <volume name>` - Volume Name
  Specifies the name of the SnapLock compliance volume for which the list of files under legal-hold is to be dumped.

- `-output-volume <volume name>` - Output Volume Name
  Specifies the name of the output volume containing the output directory path where the list of files under legal-hold is to be dumped. The output volume must be a regular read-write volume.

- `-output-directory-path <text>` - Path Relative to Output Volume Root
  Specifies the output directory path relative to the output volume root, where the list of files under legal-hold is to be dumped. The output directory path should be of the form "/directory-path". If output needs to be dumped on the volume root, specify the path as "/".

**Examples**
The following example starts a legal-hold dump-files operation:

```bash
vs1::> snaplock legal-hold dump-files -volume voll_slc -litigation-name lit1 -output-
volume voll -output-directory-path /d1
SnapLock legal-hold dump-files operation is queued. Run "snaplock legal-hold show -
operation-id 16842754 -instance" to view the operation status.
```

**snaplock legal-hold dump-litigations**

Dump list of litigations for a given Vserver to specified output path.

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.
**Description**

The `snaplock legal-hold dump-litigations` is used to dump the list of litigations for a given vserver to a user specified path. Under the user specified path, we create a directory with a unique name. Under the user specified path, a directory with an auto-generated name is created. Under this directory, multiple files are created. Each file represents a unique litigation name that was found in the given vserver. Each file contains a list of volume names that have files under legal-hold for that given litigation. For example, if the file name is "lit1" and the contents of the file are "volume1" and "volume2", then it indicates that both these volumes have files under legal-hold for litigation "lit1". Only a user with security login role `vsadmin-snaplock` is allowed to perform this operation.

**Parameters**

- `vserver <vserver name>` - Vserver Name
  Specifies the name of the Vserver for which the list of litigations is to be dumped.

- `[-volume <volume name>]` - Volume Name
  If this parameter is specified, the command displays the list of litigations for volume that matches the specified value. The volume must be of type SnapLock compliance.

- `output-volume <volume name>` - Output Volume Name
  Specifies the name of the output volume containing the output directory path where the list of litigations is to be dumped. The output volume must be a regular read-write volume.

- `output-directory-path <text>` - Path Relative to Output Volume Root
  Specifies the output directory path relative to the volume root, where the list of litigations is to be dumped. The output directory path should be of the form "/directory-path". If output needs to be dumped to the volume root, specify the path as "/".

**Examples**

The following example starts a legal-hold dump-litigations job:

```bash
vsl::> snaplock legal-hold dump-litigations -output-volume v01 -output-directory-path /d1
Dump Litigations job for Vserver "vsl" has been queued. Run "job show -id 22 -instance" to view the status.
vsl::>
```

**snaplock legal-hold end**

Starts an operation to release legal-hold on files in the user specified path on a SnapLock compliance volume.

**Availability:** This command is available to cluster and Vserver administrators at the `admin` privilege level.

**Description**

The `snaplock legal-hold end` command is used to release legal-hold on specified file or files for a given litigation. Only a user with security login role `vsadmin-snaplock` is allowed to perform this operation.

**Parameters**

- `vserver <vserver name>` - Vserver Name
  Specifies the name of the Vserver which owns the volume. The specified file or files to be released from legal-hold reside on this volume.

- `litigation-name <text>` - Litigation Name
  Specifies the name of the litigation for which the file or files have to release from legal-hold.
-volume <volume name> - Volume
   Specifies the name of the SnapLock compliance volume on which the file or files to be released from legal-hold reside.

-path <text> - Path
   Specifies a path relative to the volume root. The path can be either a file path of the single file to be released from legal-hold or a directory path where all regular files under it must be released from legal-hold.

Examples
The following example starts a legal-hold end operation on file file1 in volume slc_vol1:

```
vs1::> snaplock legal-hold end -litigation-name litigation1 -volume slc_vol1 -path /file1
SnapLock legal-hold end operation is queued. Run "snaplock legal-hold show -operation-id 16842773 -instance" to view the operation status.
```

The following example starts a legal-hold end operation on all files in the volume slc_vol1:

```
vs1::> snaplock legal-hold end -litigation-name litigation1 -volume slc_vol1 -path /
SnapLock legal-hold end operation is queued. Run "snaplock legal-hold show -operation-id 16842775 -instance" to view the operation status.
```

snaplock legal-hold show
Show status of a legal-hold operation.

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The snaplock legal-hold show command displays the status of a legal-hold operation. Information about completed operations will be cleaned up after an hour of completion. Only a user with security login role vsadmin-snaplock is allowed to perform this operation.

Parameters

- [-fields <fieldname>, ...]
  If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

- [-instance]
  If you specify the -instance parameter, the command displays detailed information about all fields.

- [-vserver <vserver name>] - Vserver Name
  If this parameter is specified, the command displays all legal-hold operations that match the specified Vserver.

- [-operation-id <integer>] - Operation ID
  If this parameter is specified, the command displays all legal-hold operations that match the specified operation ID.

- [-volume <volume name>] - Volume Name
  If this parameter is specified, the command displays all legal-hold operations that match the specified volume.
  The parameter specifies the volume on which legal-hold operation is running or has completed.
[\text{-path <text>}] - Path

If this parameter is specified, the command displays all legal-hold operations that match the specified path. The parameter specifies the path on which legal-hold operation is running or has completed.

[\text{-litigation-name <text>}] - Litigation Name

If this parameter is specified, the command displays all legal-hold operations that match the specified litigation name. The parameter specifies the legal-hold litigation name.

[\text{-operation-type \{unknown|begin|end|dump-files\}}] - Operation Type

If this parameter is specified, the command displays all legal-hold operations that match the specified operation type. The parameter specifies the type of legal-hold operation.

[\text{-operation-status \{Unknown|In-Progress|Failed|Aborting|Completed\}}] - Operation Status

If this parameter is specified, the command displays all legal-hold operations that match the specified operation status. The parameter specifies the status of legal-hold operation.

[\text{-num-files-processed <integer>}] - Number of Files Processed

If this parameter is specified, the command displays all legal-hold operations that match the specified number of files processed. The parameter specifies the number of files on which legal-hold operation was successful.

[\text{-num-files-failed <integer>}] - Number of Files Failed

If this parameter is specified, the command displays all legal-hold operations that match the specified number of files failed. The parameter specifies the number of files on which legal-hold operation failed.

[\text{-num-files-skipped <integer>}] - Number of Files Skipped

If this parameter is specified, the command displays all legal-hold operations that match the specified number of files skipped. The parameter specifies the number of files on which legal-hold begin operation was skipped. The legal-hold begin operation is skipped on a file if it is already under hold for a given litigation or if it is a hard link to a file that is already under hold for a given litigation.

[\text{-num-inodes-ignored <integer>}] - Number of Inodes Ignored

If this parameter is specified, the command displays all legal-hold operations that match the specified number of inodes ignored. The parameter specifies the number of inodes on which the legal-hold operation was not attempted because they were not regular files.

[\text{-status-details <text>}] - Status Details

If this parameter is specified, the command displays all legal-hold operations that match the specified status details. The parameter specifies the status details of an legal-hold operation.

### Examples

The following examples show the status of legal-hold operations for Vserver vs1 and volume slc_vol1 and the status of legal-hold operation for operation ID 16842786 respectively:

```
vs1::> snaplock legal-hold show -volume slc_vol1

<table>
<thead>
<tr>
<th>Operation</th>
<th>Operation ID</th>
<th>Vserver</th>
<th>Volume</th>
<th>Status</th>
</tr>
</thead>
<tbody>

snaplock legal-hold commands
SnapLock Clock commands

Manages ComplianceClock of nodes

The `snaplock compliance-clock` manages the ComplianceClock of the system. ComplianceClock determines the expiry time of the SnapLock objects in the system. ComplianceClock can be initialized only once by the user and once it is set, it cannot be changed or altered by the user. There are two types of ComplianceClocks in the system:

- System ComplianceClock
- Volume ComplianceClock

System ComplianceClock (SCC) is maintained per node. SCC is used to update the Volume ComplianceClock and to provide a base value for Volume ComplianceClock for new SnapLock volumes. The SCC is initialized once by the user and takes the initial base value from the system clock. `snaplock compliance-clock show` can be used to check the value of the System ComplianceClock.

Volume ComplianceClock (VCC) is maintained per volume and is used as the time reference to calculate the expiry time of SnapLock objects in the SnapLock volume, such as files and the expiry date of the volume. `volume snaplock show` can be used to check the value of the Volume ComplianceClock.

`volume snaplock show` on page 1644

**snaplock compliance-clock initialize**

Initializes the node ComplianceClock

**Availability:** This command is available to `cluster` administrators at the `admin` privilege level.

**Description**

`snaplock compliance-clock initialize` command is used to initialize System ComplianceClock from the system clock. System ComplianceClock can be initialized only once by the user. Once initialized, user cannot make any changes to the System ComplianceClock. Hence, user should ensure that system clock is correct before initializing the System ComplianceClock.

**Parameters**

- `-node <nodename>` - Node

  Specifies the name of the node on which System ComplianceClock needs to be initialized.

- `[-force [true]]` - Forces Initialization

  If you use this parameter, it will suppress the warning message during `snaplock compliance-clock initialize` operation.
Examples

cluster-1::> snaplock compliance-clock initialize -node node1

Warning: You are about to initialize the secure ComplianceClock of the node
cnode1 to the current value of the node's system clock. This
procedure can be performed only once on a given node, so you should
ensure that the system time is set correctly before proceeding.
The current node's system clock is: Wed Nov 26 16:18:30 IST 2014

Do you want to continue? {y|n}: y
cluster-1::>

snaplock compliance-clock show

Displays the node ComplianceClock

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The snaplock compliance-clock show command will display System ComplianceClock of the nodes in the cluster. It will
display the following information:

- Node name
- ComplianceClock Time

Parameters

[-fields <fieldname>, ...]
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified
field or fields. You can use '-fields ?' to display the fields to specify.

[-instance]
If you specify the -instance parameter, the command displays detailed information about all fields.

[-node {<nodename>|local}] - Node
If this parameter is specified, the command will display ComplianceClock for that particular node only.

[-time <text>] - ComplianceClock Time of the Node
If this parameter is specified, the command will display nodes having the same -time value.

Examples

    cluster1::> snaplock compliance-clock show
    Node                  ComplianceClock Time
    --------------------- -----------------------------------
    node1                 Mon Jan 12 11:34:15 IST 2015 +05:30
    node2                 Mon Jan 12 11:34:10 IST 2015 +05:30
    2 entries were displayed.
snaplock compliance-clock ntp commands

The ntp directory

snaplock compliance-clock ntp modify

Modify SnapLock ComplianceClock synchronization setting

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
The snaplock compliance-clock ntp modify command modifies the option to enable or disable the SnapLock ComplianceClock synchronization with the system time. The ComplianceClock is synchronized only when an NTP server has been configured so that the system time follows the NTP time and the skew between the ComplianceClock time and the system time is greater than 1 day.

Parameters
[-is-sync-enabled {true|false}] - Enable ComplianceClock sync to NTP system time

Specifies whether synchronization should be enabled or not. This is a cluster wide option.

Examples

cluster1::> snaplock compliance-clock ntp modify -is-sync-enabled true
snaplock compliance-clock ntp show

Display SnapLock ComplianceClock synchronization setting

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
The snaplock compliance-clock ntp show command will display ComplianceClock synchronization setting. It will display the following information:

• is-sync-enabled - Displays if the option to synchronize the ComplianceClock with system time has been enabled or not.

Examples

```
cluster1::> snaplock compliance-clock ntp show
Enable clock sync to NTP system time: true
```

snaplock event-retention commands

SnapLock Event Based Retention commands

snaplock event-retention abort

Abort an Event Based Retention policy operation.

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The snaplock event-retention abort is used to abort an ongoing Event Based Retention (EBR) operation. This command only aborts the operations that have not yet completed. Only a user with security login role vsadmin-snaplock is allowed to perform this operation.

Parameters
-vserver <vserver name> - Vserver Name
   Specifies the vserver on which the EBR operation is running.
-operation-id <integer> - Operation ID
   Specifies the operation ID of the EBR operation that needs to be aborted.

Examples

The following example aborts an ongoing EBR operation with operation-id 16842754:

```
vs1::> snaplock event-retention abort -operation-id 16842754
vs1::>
```
**snaplock event-retention apply**

Apply an Event Based Retention policy on all files within a user specified path.

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

**Description**
The `snaplock event-retention apply` command starts a new operation to apply the specified Event Based Retention (EBR) policy to all files in the specified path. If a file is a regular file, it will be made a WORM file and retained for a retention-period as defined by the specified policy name. If a file is already WORM, its retention time will be extended to a retention-period as defined by the specified policy name, starting from the current time. The retention time of a file will be extended only if the file's current retention time is less than the new retention time value to be set. Only a user with security login role `vsadmin-snaplock` is allowed to perform this operation.

**Parameters**
- `vserver <vserver name>` - *Vserver Name*
  Specifies the name of the Vserver which has the EBR policy defined to be applied on one or more files.
- `policy-name <text>` - *Policy Name*
  Specifies the name of the EBR policy to be applied on one or more files.
- `volume <volume name>` - *Volume*
  Specifies the name of the SnapLock volume containing a file path or a directory path as specified by the path parameter. The specified EBR policy is applied to one or more files depending on the value of path.
- `path <text>` - *Path*
  Specifies the path relative to the output volume root, of the form "/path". The path can be path to a file or a directory. The EBR policy is applied to all files under the specified path. To apply the EBR policy to all files in a volume, specify the path as "/".

**Examples**
The following example starts an EBR operation to apply a policy on files for specified volume:

```
vs1:/> snaplock event-retention apply -policy-name p1 -volume slc -path /
SnapLock event based retention operation is queued. Run "snaplock event-retention show -operation-id 16842754 -instance" to view the operation status.
```

**snaplock event-retention show**

Show status of Event Based Retention operation

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

**Description**
The `snaplock event-retention show` command displays the status of an Event Based Retention (EBR) operation. Information about completed operations will be cleaned up after an hour after completion. Only a user with security login role `vsadmin-snaplock` is allowed to perform this operation.

**Parameters**

```
{ [-fields <fieldname>, ...]  
   If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.
```
If you specify the `-instance` parameter, the command displays detailed information about all fields.

`[-vserver <vserver name>] - Vserver Name`
If this parameter is specified, the command displays all EBR operations that match the specified Vserver.

`[-operation-id <integer>] - Operation ID`
If this parameter is specified, the command displays all EBR operations that match the specified operation ID.

`[-volume <volume name>] - Volume Name`
If this parameter is specified, the command displays all EBR operations that match the specified volume. The parameter specifies the volume on which EBR operation is running or has completed.

`[-path <text>] - Path`
If this parameter is specified, the command displays all EBR operations that match the specified path. The parameter specifies the path on which EBR operation is running or has completed.

`[-policy-name <text>] - Policy Name`
If this parameter is specified, the command displays all EBR operations that match the specified policy name. The parameter specifies the EBR policy name.

`[-retention-period {{<integer> seconds|minutes|hours|days|months|years} | infinite}] - Retention Period`
If this parameter is specified, the command displays all EBR operations that match the specified retention period. The parameter specifies the retention period of the EBR policy.

`[-num-files-processed <integer>] - Number of Files Processed`
If this parameter is specified, the command displays all EBR operations that match the specified number of processed files. The parameter specifies the number of files on which EBR policy was applied successfully.

`[-num-files-failed <integer>] - Number of Files Failed`
If this parameter is specified, the command displays all EBR operations that match the specified number of failed files. The parameter specifies the number of files on which the application of EBR policy failed.

`[-num-files-skipped <integer>] - Number of Files Skipped`
If this parameter is specified, the command displays all EBR operations that match the specified number of skipped files. The parameter specifies the number of files on which the application of EBR policy was skipped. A file that is under legal-hold will be skipped. If the retention time of a file is being shortened as a result of applying the EBR policy, that file will also be skipped.

`[-num-inodes-ignored <integer>] - Number of Inodes Ignored`
If this parameter is specified, the command displays all EBR operations that match the specified number of ignored inodes. The parameter specifies the number of inodes on which the application of EBR policy was not attempted because they were not regular files.

`[-operation-status {Unknown|In-Progress|Failed|Aborting|Completed}] - Operation Status`
If this parameter is specified, the command displays all EBR operations that match the specified operation status. The parameter specifies the operation status of an EBR operation.

`[-status-details <text>] - Status Details`
If this parameter is specified, the command displays all EBR operations that match the specified status details. The parameter specifies the status details of an EBR operation.

### Examples

The following examples show the status of EBR operations for Vserver "vs1" and volume "slc" and the status of event-retention operation for operation ID 16842753 respectively.
snaplock event-retention operation show -volume slc

snaplock event-retention show-vservers

Show Vservers with SnapLock Event Based Retention policies

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description

The snaplock event-retention show-vservers command is used to display the Vservers that have SnapLock Event Based Retention (EBR) policies created.

Parameters

[-fields <fieldname>, ...]

If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

Examples

The following example displays all Vservers that have SnapLock EBR policies:

    cluster-1::*> snaplock event-retention show-vservers
    Vserver
    -----------------
    vs1

snaplock event-retention policy commands

SnapLock Event Based Retention policy commands

snaplock event-retention policy create

Create SnapLock Event Based Retention policies for a Vserver

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.
Description
The `snaplock event-retention policy create` command is used to create Event Based Retention (EBR) policies for a Vserver. A policy consists of a `policy-name` and a `retention-period`. Only a user with security login role `vsadmin-snaplock` is allowed to perform this operation.

Parameters
- `vserver <vserver name>` - Vserver Name
  Specifies the name of the Vserver for which a policy needs to be created.
- `name <text>` - Policy Name
  Specifies the name of the EBR policy to be created.
- `retention-period {<integer> seconds|minutes|hours|days|months|years} | infinite}` - Event Retention Period
  Specifies the retention period for an EBR policy.

Examples
The following example creates a new EBR policy "p1" for Vserver "vs1" with a retention period of "10 years":

```
vs1::> snaplock event-retention policy create -name p1 -retention-period "10 years"
```

snaplock event-retention policy delete
Delete SnapLock Event Based Retention policies for a Vserver

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The `snaplock event-retention policy delete` command is used to delete Event Based Retention (EBR) policies for a Vserver. Only a user with security login role `vsadmin-snaplock` is allowed to perform this operation.

Parameters
- `vserver <vserver name>` - Vserver Name
  If this parameter is specified, the command deletes all EBR policies that match the specified Vserver.
- `name <text>` - Policy Name
  If this parameter is specified, the command deletes all EBR policies that match the specified `name`.

Examples
The following example deletes retention policy "p1" for Vserver "vs1":

```
vs1::> snaplock event-retention policy delete -name p1
```

snaplock event-retention policy modify
Modify SnapLock Event Based Retention policies for a Vserver

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.
Description
The snaplock event-retention policy modify command is used to modify the retention period of an Event Based Retention (EBR) policy for a Vserver. Only a user with security login role vsadmin-snaplock is allowed to perform this operation.

Parameters
-vserver <vserver name> - Vserver Name
   Specifies the name of the Vserver for which retention period of a policy needs to be modified.
-name <text> - Policy Name
   Specifies the name of the EBR policy for which the retention period needs to be modified.
[-retention-period {{<integer> seconds|minutes|hours|days|months|years} | infinite}] - Event Retention Period
   Specifies the new value of retention period.

Examples
The following example modifies the retention period of policy "p1" for Vserver "vs1" to "5 years":

    vs1::> snaplock event-retention policy modify -name p1 -retention-period "5 years"

snaplock event-retention policy show
Show SnapLock Event Based Retention policies for a Vserver

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The snaplock event-retention policy show command is used to show Event Based Retention (EBR) policies for a Vserver. A policy consists of a policy-name and a retention-period. The command output depends on the parameter or parameters specified. If no parameters are specified, all policies for all vservers will be displayed. If one or more parameters are specified, only those entries matching the specified values will be displayed. Only a user with security login role vsadmin-snaplock is allowed to perform this operation.

Parameters
[-fields <fieldname>, ...]
   If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.
[-instance ]
   If you specify the -instance parameter, the command displays detailed information about all fields.
-vserver <vserver name> - Vserver Name
   If this parameter is specified, the command displays all EBR policies that match the specified Vserver.
-name <text> - Policy Name
   If this parameter is specified, the command displays all EBR policies that match the specified name.
[-retention-period {{<integer> seconds|minutes|hours|days|months|years} | infinite}] - Event Retention Period
   If this parameter is specified, the command displays all EBR policies that match the specified retention-period.
Examples
The following example displays all event-retention policies for vserver "vs1":

```
vs1::> snaplock event-retention policy show

<table>
<thead>
<tr>
<th>Vserver</th>
<th>Name</th>
<th>Retention Period</th>
</tr>
</thead>
<tbody>
<tr>
<td>vs1</td>
<td>p1</td>
<td>10 years</td>
</tr>
<tr>
<td>vs1</td>
<td>p2</td>
<td>5 years</td>
</tr>
</tbody>
</table>
```

SnapLock Log commands

Create and manage audit log configuration for a Vserver.

The `snaplock log` commands manage SnapLock log infrastructure for the SnapLock feature. This infrastructure provides the capability to record events that are required to provide an audit trail. These commands enable you to create and initialize the SnapLock log configuration for the Vserver, modify attributes associated with the SnapLock log configuration, and delete the auditlog configuration. Attributes of a SnapLock log configuration include the following:

- SnapLock log volume
- Maximum log size
- Default retention period

The SnapLock log volume is a SnapLock Compliance volume. The SnapLock log infrastructure creates directories and files in this volume to store the SnapLock log records.

The maximum log size specifies the maximum size of a log file that stores SnapLock log records. Once the file reaches this size, it is archived and a new log file is created.

The default retention period is the time period for which the log file is retained, if the SnapLock log records that are stored in the file do not carry any retention period.

`snaplock log create`

Create audit log configuration for a Vserver.

**Availability:** This command is available to `cluster` and `Vserver` administrators at the `admin` privilege level.

**Description**
The `snaplock log create` command is used to create a SnapLock log configuration for the Vserver. A SnapLock log configuration consists of volume to store the log, the maximum size of the log file, and the default period of time for which the log file should be retained.

**Parameters**
- `--vserver <vserver name>` - Vserver Name
  - Specifies the name of the Vserver for which the configuration needs to be created.

- `--volume <volume name>` - Log Volume Name
  - Specifies the name of the volume that is used for logging. This must be a SnapLock Compliance volume.

- `[-max-log-size <integer>[KB|MB|GB|TB|PB]]` - Maximum Size of Log File
  - Specifies the maximum size of the log file. Once a log file reaches this limit, it is archived and a new log file is created. This parameter is optional. The default value is 10MB.
- Default Log Record Retention Period

Specifies the default period of time a record (which is logged) is retained. This parameter is optional. The default value is "6 months".

Examples

```
  cluster1::> snaplock log create -volume voll -max-log-size 50MB -default-retention-period "1 year" -vserver vs1
  [Job 47] Job succeeded: SnapLock log created for Vserver "vs1".
```

### snaplock log delete

Delete audit log configuration for a Vserver.

**Availability:** This command is available to cluster and Vserver administrators at the admin privilege level.

**Description**
The `snaplock log delete` command deletes the SnapLock log configuration associated with the Vserver. This command closes all the active log files in the log volume and marks the volume as disabled for SnapLock logging.

**Parameters**

- **-vserver <vserver name>** - Vserver Name
  
  Specifies the name of the Vserver whose SnapLock log configuration is deleted.

Examples

```
  cluster1::> snaplock log delete -vserver vs1
  [Job 47] Job succeeded: SnapLock log deleted for Vserver "vs1".
```

### snaplock log modify

Modify audit log configuration for a Vserver.

**Availability:** This command is available to cluster and Vserver administrators at the admin privilege level.

**Description**
The `snaplock log modify` command modifies the SnapLock log configuration of the Vserver. Log volume, maximum size of log file, and default retention period can be modified. If the log volume is modified, then the active log files in the existing log volume are closed and the log volume is marked as disabled for logging. The new log volume is enabled for logging.

**Parameters**

- **-vserver <vserver name>** - Vserver Name
  
  Specifies the name of the Vserver for which the SnapLock log configuration needs to be modified.

- **[-volume <volume name>]** - Log Volume Name
  
  Specifies the new log volume that is configured for this Vserver for logging.

- **[-max-log-size (<integer> [KB|MB|GB|TB|PB])]** - Maximum Size of Log File
  
  Specifies the new value for maximum log file size.
[-default-retention-period {{<integer> seconds|minutes|hours|days|months|years} | infinite}] 
- Default Log Record Retention Period
  Specifies the new value for default retention period.

Examples

```
cluster1::> snaplock log modify -volume vol1 -vserver vs1 -max-log-size 15MB
[Job 48] Job succeeded: SnapLock log modified for Vserver "vs1".
```

```
snaplock log show
Display audit log configuration.

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The snaplock log show command displays the following information about the SnapLock log infrastructure:

- Vserver name
- Volume name
- Maximum log size
- Default retention period

Parameters

{ [-fields <fieldname>, ...] If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified
  field or fields. You can use -fields ? to display the fields to specify.

[[-instance]] If you specify the -instance parameter, the command displays detailed information about all fields.

[-vserver <vserver name>] - Vserver Name
  If this parameter is specified, the command displays the log information for Vserveers that match the specified
  value.

[-volume <volume name>] - Log Volume Name
  If this parameter is specified, the command displays the log configuration for volumes that match the specified
  value.

[-max-log-size {<integer> [KB|MB|GB|TB|PB]}] - Maximum Size of Log File
  If this parameter is specified, the command displays the log configuration with a matching -max-log-size
  value.

[-default-retention-period {{<integer> seconds|minutes|hours|days|months|years} | infinite}] - Default Log Record Retention Period
  If this parameter is specified, the command displays the log configuration with a matching -default-
  retention-period value.

SnapLock Log File commands

Manage Audit Log files of a Vserver.

The `snaplock log file` commands manage the log files used for recording events that need to be logged. Commands in this directory enable you to archive and close log files and display active log files.

`snaplock log file archive`

Archive Active Log Files in Log Volume

**Availability:** This command is available to cluster and Vserver administrators at the `admin` privilege level.

**Description**
The `snaplock log file archive` command archives the currently active log file by closing it and creating a new active log file. If `base-name` is not provided, the command archives all active log files associated with the Vserver. Otherwise, the command archives the active log file associated with the `base-name` provided.

**Parameters**

- `-vserver <vserver name>` - Vserver Name
  
  Specifies the name of the Vserver for which active log files need to be archived.

- `[–base-name {privileged-delete | system | legal-hold}]` - Base Name of Log File
  
  Specifies the log base-name, whose active log file needs to be archived. The base-name is the name of the source of log records. Valid base-names are `system`, `privileged-delete` and `legal-hold`. Each base-name has its own directory in which log files containing log records generated by base-name are stored.

**Examples**

class1::> snaplock log archive -vserver vs1
[Job 48] Job succeeded: Snaplock log archived for Vserver "vs1".

`snaplock log file show`

Display audit log file information.

**Availability:** This command is available to cluster and Vserver administrators at the `admin` privilege level.
Description
The snaplock log file show command displays the following information about the log files:

- Vserver name
- Volume name
- File path
- Expiry time of the file
- File size

Parameters

```
[-fields <fieldname>, ...]  # If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

[-instance]  # If you specify the -instance parameter, the command displays detailed information about all fields.

[-vserver <vserver name>] - Vserver Name
If this parameter is specified, then log files in the Vserver that match the specified value is displayed.

[-base-name {privileged-delete | system | legal-hold}] - Base Name of Log File
If this parameter is specified, then the log files having a matching -base-name is displayed.

[-volume <volume name>] - Log Volume Name
If this parameter is specified, then the log files in volumes that match the specified value are shown.

[-file-path <text>] - Log File Path
If this parameter is specified, then the log files that match the specified value are displayed.

[-expiry-time <text>] - Log File Expiry Time
If this parameter is specified, then the log files having a matching -expiry-time value are displayed.

[-file-size \{<integer> [KB|MB|GB|TB|PB]\}] - File Size
If this parameter is specified, then the log files having a matching -file-size value are displayed.
```

Examples

```
cluster1::> snaplock log file show
Vserver           Volume              Base Name           File Path
----------------- ------------------- ------------------- -------------------
vs1               vol1                system              /vol/vol1/snaplock_log/
                   system_logs/20160120_183756_GMT-present

cluster1::> snaplock log file show -vserver vs1 -base-name system
Vserver : vs1
Volume : vol1
Base Name : system
File Path : /vol/vol1/snaplock_log/system_logs/20160120_183756_GMT-present
File Size : 560B
```

SnapLock Log commands
SnapMirror Commands

Manage SnapMirror

The `snapmirror` commands enable you to create and manage data protection mirrors, extended data protection relationships, and load-sharing mirrors.

These commands are available to the cluster and Vserver administrators.

Note that there are "Pre 8.2" relationships: (1) load-sharing relationships; (2) data protection relationships with the source volume on a storage system running clustered Data ONTAP 8.1; (3) data protection relationships that existed before the source and destination storage systems were upgraded from clustered Data ONTAP 8.1 to clustered Data ONTAP 8.2 and later and have not yet been converted to ones with Data ONTAP 8.2 capabilities. These relationships have the same limitations as on Data ONTAP 8.1. In particular, only `snapmirror` commands present on Data ONTAP 8.1 can be used for these relationships. The "Relationship Capability" field, as shown in the output of the `snapmirror show` command, is set to "Pre 8.2" for these relationships. "Pre 8.2" data protection relationships can only be created and managed by the cluster administrator; load-sharing relationships which are all "Pre 8.2" can be created and managed by either a cluster or Vserver administrator.

Data protection relationships that existed before the source and destination storage systems were upgraded from Data ONTAP 8.1 will be auto-converted to "8.2 and above" with full capabilities when a Vserver peering relationship is set up between the source and destination Vservers. Relationships that have both the source and destination in the same Vserver and therefore require no Vserver peering relationship will be converted on the first boot when all nodes in the storage system are running Data ONTAP 8.2 or later. Note that since there is no "8.2 and above" implementation of load-sharing relationships, there is no conversion of load-sharing relationships to "8.2 and above".

When a SnapMirror relationship is created with the type of the relationship specified as data protection (DP), an extended data protection (XDP) relationship will be created. This relationship will provide the same functional behavior as the DP type in terms of Snapshot copy selection and retention. This is achieved by using a policy which has the rule to replicate all Snapshot copies. There is an exception to this relationship creation behavior of overriding of the type DP. If a relationship of type DP in the opposite direction already exists, the new relationship will also be of type DP. The type DP will eventually be deprecated and applications should not use this type when creating new relationships. When the type is specified as DP or when no type is specified, if a policy of type async-mirror is specified that does not have the rule to replicate all Snapshot copies, the `snapmirror create` command will fail.

snapmirror abort

Abort an active transfer

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

**Description**

The `snapmirror abort` command stops SnapMirror transfers that might have started and not completed. A SnapMirror transfer is an operation on a given SnapMirror relationship and the relationship is identified by its destination endpoint, which can be a volume, a Vserver, or a non-Data ONTAP endpoint. You identify the SnapMirror relationship with this command and the command aborts the transfer for the relationship. For load-sharing mirrors, the command also aborts transfers for other relationships that are part of the same load-sharing set. For SolidFire destination endpoints, the `snapmirror abort` command is only supported if the endpoint is in a SnapMirror relationship.
Load-sharing mirrors are either up to date and serving data to clients, or they are lagging and not serving data to clients. If the `snapmirror abort` command identifies an up-to-date load-sharing mirror, then SnapMirror transfers to the up-to-date load-sharing mirror and associated up-to-date load-sharing mirrors in the set of load-sharing mirrors are aborted. If the `snapmirror abort` command identifies a lagging load-sharing mirror, then only the SnapMirror transfer associated with the lagging load-sharing mirror is aborted.

After the `snapmirror abort` command successfully completes its operation, the volume on the receiving side of the transfer might contain a restart checkpoint. The restart checkpoint can be used by a subsequent transfer to restart and continue the aborted SnapMirror transfer.

This command is supported for SnapMirror relationships with the field "Relationship Capability" showing as either "8.2 and above" or "Pre 8.2" in the output of the `snapmirror show` command.

The use of wildcards in parameter values is not supported from the source Vserver or cluster for relationships with "Relationship Capability" of "8.2 and above".

You can use this command from the source or the destination Vserver or cluster for FlexVol volume relationships.

For SnapMirror Synchronous relationships, this command aborts any ongoing transfer and takes the relationship OutOfSync. This can result in primary client IO failure for relationships with a policy of type `strict-sync-mirror`. Instead, the best practice recommendation is to use the `snapmirror quiesce` command.

For Vserver SnapMirror relationships, this command must be run only from the cluster containing the destination Vserver.

**Parameters**

```bash
{-source-path} [-S {[@vserver:]@volume} [@vserver:/volume] | <hostip:/lun/name> | <hostip:/share/share-name>] - Source Path
```

This parameter specifies the source endpoint of the SnapMirror relationship in one of four path formats. The normal format includes the names of the Vserver (vserver) and/or the volume (volume). To support relationships with "Relationship Capability" of "Pre 8.2", a format which also includes the name of the cluster (cluster) is provided. The "Pre 8.2" format cannot be used when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above". For SnapMirror relationships with an AltaVault source, the source endpoint is specified in the form `hostip:/share/share-name`. For SnapMirror relationships with a SolidFire source, the source endpoint is specified in the form `hostip:/lun/name`.

```bash
[-source-cluster <Cluster name>] - Source Cluster
```

Specifies the source cluster of the SnapMirror relationship. If this parameter is specified, the `-source-vserver` and `-source-volume` parameters must also be specified. This parameter is only applicable for relationships with "Relationship Capability" of "Pre 8.2". This parameter cannot be specified when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above".

```bash
[-source-vserver <vserver name>] - Source Vserver
```

Specifies the source Vserver of the SnapMirror relationship. For relationships with volumes as endpoints, if this parameter is specified, parameters `-source-volume` and for relationships with "Relationship Capability" of "Pre 8.2", `-source-cluster` must also be specified. This parameter is not supported for relationships with non-Data ONTAP source endpoints.

```bash
[-source-volume <volume name>] - Source Volume
```

 Specifies the source volume of the SnapMirror relationship. If this parameter is specified, parameters `-source-vserver` and for relationships with "Relationship Capability" of "Pre 8.2", `-source-cluster` must also be specified. This parameter is not supported for relationships with non-Data ONTAP source endpoints.

```bash
{-destination-path} [@vserver:]@volume] [@vserver:/volume] | <hostip:/lun/name> | <hostip:/share/share-name>] - Destination Path
```

This parameter specifies the destination endpoint of the SnapMirror relationship in one of four path formats. The normal format includes the names of the Vserver (vserver) and/or volume (volume). To support
relationships with "Relationship Capability" of "Pre 8.2", a format which also includes the name of the cluster (cluster) is provided. The "Pre 8.2" format cannot be used when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above". For SnapMirror relationships with AltaVault destinations, the destination endpoint is specified in the form hostip:/share/share-name. For relationships with SolidFire destinations, the destination endpoint is specified in the form hostip:/lun/name.

| [-destination-cluster <Cluster name>] - Destination Cluster

Specifies the destination cluster of the SnapMirror relationship. If this parameter is specified, parameters -destination-vserver and -destination-volume must also be specified. This parameter is only applicable for relationships with "Relationship Capability" of "Pre 8.2". This parameter cannot be specified when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above".

-destination-vserver <vserver name> - Destination Vserver

Specifies the destination Vserver of the SnapMirror relationship. For relationships with volumes as endpoints, if this parameter is specified, parameters -destination-volume and for relationships with "Relationship Capability" of "Pre 8.2", -destination-cluster must also be specified. This parameter is not supported for relationships with non-Data ONTAP destination endpoints.

-destination-volume <volume name> - Destination Volume

Specifies the destination volume of the SnapMirror relationship. If this parameter is specified, parameters -destination-vserver and for relationships with "Relationship Capability" of "Pre 8.2", -destination-cluster must also be specified. This parameter is not supported for relationships with non-Data ONTAP destination endpoints.

[-hard | -h [true]] - Discard Restart Checkpoint

If this option is specified true, the restart checkpoint is discarded and the destination volume is restored to the last Snapshot copy that was successfully transferred. You can use the -hard option to discard the restart checkpoint of a previous transfer attempt which forces the subsequent transfer to start with a fresh Snapshot copy on the destination volume. This option can only be used from the destination Vserver or cluster. This parameter is not supported for relationships with non-Data ONTAP endpoints.

[-foreground | -w [true]] - Foreground Process

This specifies whether the operation runs as a foreground process. If this parameter is specified, the default setting is true (the operation runs in the foreground). When set to true, the command will not return until the process completes. This parameter is only applicable to relationships with "Relationship Capability" of "Pre 8.2".

Examples

To stop the active SnapMirror replication to the destination volume vs2.example.com:dept_eng_dp_mirror1, type the following command:

```
vs2.example.com::> snapmirror abort -destination-path
vs2.example.com:dept_eng_dp_mirror1
```

For relationships with "Relationship Capability" of "Pre 8.2", to stop the active SnapMirror replication to the destination volume cluster2://vs2.example.com/dept_eng_dp_mirror1, type the following command:

```
cluster2::> snapmirror abort -destination-path
cluster2://vs2.example.com/dept_eng_dp_mirror1
```

To stop the active SnapMirror replication to the destination Vserver dvs1.example.com, type the following command:

```
cluster2::> snapmirror abort -destination-path
dvs1.example.com:
```
Under PVR control to stop user-initiated active SnapMirror replication to the destination Consistency Group `cg_dst` in Vserver `vs2.example.com`, type the following command:

```bash
vs2.example.com::> snapmirror abort -destination-path
vs2.example.com:/cg/cg_dst
```

## snapmirror break

Make SnapMirror destination writable

### Availability

This command is available to `cluster` and `Vserver` administrators at the `admin` privilege level.

### Description

The `snapmirror break` command breaks a SnapMirror relationship between a source and destination endpoint of a data protection mirror. The destination endpoint can be a Vserver, volume or SolidFire endpoint. When Data ONTAP breaks the relationship, if the endpoint is a volume or SolidFire endpoint, the destination is made read/write and can diverge from the source volume, client redirection is turned off on the destination, the restart checkpoint is cleared, and the clients can see the latest Snapshot copy. If the endpoint is a Vserver, the subtype of the destination Vserver is changed to `default`, volumes in the destination Vserver are made read/write and the clients can now access the Vserver namespace for modifications. For SolidFire destination endpoints, the `snapmirror break` command is only supported if the endpoint is in a SnapMirror relationship.

Subsequent manual or scheduled SnapMirror updates to the broken relationship will fail until the SnapMirror relationship is reestablished using the `snapmirror resync` command.

This command applies to data protection mirrors. For vault relationships, this command is only intended for use when preparing for a Data ONTAP revert operation (see the `-delete-snapshots` parameter in advanced privilege level). This command is not intended for use with load-sharing mirrors.

For relationships with a policy of type `strict-sync-mirror` or `sync-mirror`, the relationship must be Quiesced before running the `snapmirror break` command.

This command is supported for SnapMirror relationships with the field `"Relationship Capability"` showing as either "8.2 and above" or "Pre 8.2" in the output of the `snapmirror show` command.

The `snapmirror break` command must be used from the destination Vserver or cluster.

### Parameters

```
[-source-path | -S {<vserver:/|volume> | <cluster://vserver/|volume> | <hostip:/lun/name> | <hostip:/share/share-name>}] - Source Path
```

This parameter specifies the source endpoint of the SnapMirror relationship in one of four path formats. The normal format includes the names of the Vserver (vserver) and/or the volume (volume). To support relationships with `"Relationship Capability"` of "Pre 8.2", a format which also includes the name of the cluster (cluster) is provided. The "Pre 8.2" format cannot be used when operating in a Vserver context on relationships with `"Relationship Capability"` of "8.2 and above". For SnapMirror relationships with an AltaVault source, the source endpoint is specified in the form `hostip:/share/share-name`. For SnapMirror relationships with a SolidFire source, the source endpoint is specified in the form `hostip:/lun/name`. 
[-source-cluster <Cluster name>] - Source Cluster

Specifies the source cluster of the SnapMirror relationship. If this parameter is specified, the -source-vserver and -source-volume parameters must also be specified. This parameter is only applicable for relationships with "Relationship Capability" of "Pre 8.2". This parameter cannot be specified when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above".

[-source-vserver <vserver name>] - Source Vserver

Specifies the source Vserver of the SnapMirror relationship. For relationships with volumes as endpoints, if this parameter is specified, parameters -source-volume and for relationships with "Relationship Capability" of "Pre 8.2", -source-cluster must also be specified. This parameter is not supported for relationships with non-Data ONTAP source endpoints.

[-source-volume <volume name>] - Source Volume

Specifies the source volume of the SnapMirror relationship. If this parameter is specified, parameters -source-vserver and for relationships with "Relationship Capability" of "Pre 8.2", -source-cluster must also be specified. This parameter is not supported for relationships with non-Data ONTAP source endpoints.

{-destination-path {<[vserver:]/[volume]>|[<cluster://vserver]/volume>|<hostip:/lun/name>|<hostip:/share/share-name>}} - Destination Path

This parameter specifies the destination endpoint of the SnapMirror relationship in one of four path formats. The normal format includes the names of the Vserver (vserver) and/or volume (volume). To support relationships with "Relationship Capability" of "Pre 8.2", a format which also includes the name of the cluster (cluster) is provided. The "Pre 8.2" format cannot be used when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above". For SnapMirror relationships with AltaVault destinations, the destination endpoint is specified in the form hostip:/share/share-name. For relationships with SolidFire destinations, the destination endpoint is specified in the form hostip:/lun/name.

[-destination-cluster <Cluster name>] - Destination Cluster

Specifies the destination cluster of the SnapMirror relationship. If this parameter is specified, parameters -destination-vserver and -destination-volume must also be specified. This parameter is only applicable for relationships with "Relationship Capability" of "Pre 8.2". This parameter cannot be specified when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above".

-destination-vserver <vserver name> - Destination Vserver

Specifies the destination Vserver of the SnapMirror relationship. For relationships with volumes as endpoints, if this parameter is specified, parameters -destination-volume and for relationships with "Relationship Capability" of "Pre 8.2", -destination-cluster must also be specified. This parameter is not supported for relationships with non-Data ONTAP destination endpoints.

-destination-volume <volume name> - Destination Volume

Specifies the destination volume of the SnapMirror relationship. If this parameter is specified, parameters -destination-vserver and for relationships with "Relationship Capability" of "Pre 8.2", -destination-cluster must also be specified. This parameter is not supported for relationships with non-Data ONTAP destination endpoints.

[-force | -f [true]] - Force

If this parameter is specified, the command proceeds without prompting for confirmation.

[-foreground | -w [true]] - Foreground Process

This specifies whether the operation runs as a foreground process. If this parameter is specified, the default setting is true (the operation runs in the foreground). When set to true, the command will not return until the process completes. This parameter is only applicable to relationships with "Relationship Capability" of "Pre 8.2".
[-delete-snapshots [true]] - Delete Snapshots for Revert (privilege: advanced)

Using this parameter causes break to delete Snapshot copies on a vault destination so that the system can be reverted. Note that the only Snapshot copies that will be deleted are those that were created with the current version of Data ONTAP. Any Snapshot copies that might be present created with a different version will not be deleted. This parameter is not supported for SnapLock Compliance destinations.

[-restore-destination-to-snapshot [-s <text>]] - Restore Destination to Snapshot Copy

This optional parameter specifies the Snapshot copy to which the destination volume is restored after a successful break operation. If the parameter is not specified, the destination is restored to the latest Snapshot copy. This parameter is not supported for Vserver or FlexGroup relationships or SnapLock Compliance destinations.

[-recover [true]] - Recover (privilege: advanced)

When a SnapMirror break operation fails on a FlexGroup relationship, a subset of the destination FlexGroup constituents could have been made writable and subsequently user data could have been written to these constituents. To recover from this failure, you can execute the `snapmirror break` command again specifying the `-recover` parameter. All constituents will be restored to the latest Snapshot copy, and any writes to the read-write constituents will be lost. This parameter is applicable only for SnapMirror relationships with FlexGroup endpoints.

**Examples**

To stop the SnapMirror replication to the destination volume `vs2.example.com:dept_eng_dp_mirror1`, type the following command:

```
vs2.example.com::> snapmirror break -destination-path vs2.example.com:dept_eng_dp_mirror1
```

For relationships with "Relationship Capability" of "Pre 8.2", to stop the SnapMirror replication to the destination volume `cluster2://vs2.example.com/dept_eng_dp_mirror1`, type the following command:

```
cluster2::> snapmirror break -destination-path cluster2://vs2.example.com/dept_eng_dp_mirror1
```

To stop replication to the destination Vserver `dvs1.example.com` of a Vserver SnapMirror relationship, type the following command:

```
cluster2::> snapmirror break -destination-path dvs1.example.com:
```

Under PVR control to stop synchronous SnapMirror replication to the destination Consistency Group `cg_dst` in Vserver `vs2.example.com`, type the following command:

```
vs2.example.com::> snapmirror break -destination-path vs2.example.com:/cg/cg_dst
```

`snapmirror resync` on page 676

`snapmirror show` on page 683

**snapmirror create**

Create a new SnapMirror relationship

**Availability:** This command is available to `cluster` and `Vserver` administrators at the `admin` privilege level.
The **snapmirror create** command creates a SnapMirror relationship between a source and destination endpoint. You can use this command to create a data protection relationship, an extended data protection relationship, or a load-sharing relationship between FlexVol volumes. You can also use it to create a data protection relationship between Vservers. A SnapMirror relationship between Vservers can only be created if the system containing the source Vserver is also running Data ONTAP 8.3 or later. You can also use the **snapmirror create** command to create an extended data protection relationship between FlexGroups. FlexGroups only support extended data protection relationships. A SnapMirror relationship between FlexGroups is only supported if the system containing the source FlexGroup volume is also running Data ONTAP 9.1.0 or later. The source or destination of a FlexGroup SnapMirror relationship cannot be the source or destination of any other SnapMirror relationship.

You can use the **snapmirror create** command to create a data protection relationship or an extended data protection relationship between SnapLock source and SnapLock destination endpoints. When the cluster containing the source is running ONTAP 9.5.0 or later, the default relationship type is extended data protection (XDP), otherwise it is data protection (DP).

A SnapMirror relationship can also be created between a non-SnapLock source and a SnapLock destination to WORM-protect Snapshot copies. In this case, the relationship type is always set to extended data protection (XDP).

The **snapmirror create** command can be used to create an extended data protection (XDP) relationship between a Data ONTAP volume and a non-Data ONTAP endpoint that supports SnapMirror (AltaVault, Solidfire). AltaVault endpoints can only be used as destinations. SolidFire endpoints can be used as sources or destinations.

The **snapmirror create** command can be used to create a synchronous relationship between FlexVol volumes, which provides zero RPO data protection. SnapMirror Synchronous supports two policy types, **sync-mirror** and **strict-sync-mirror**. Upon a permanent replication failure, the strict-sync-mirror variant restricts further client IO on the primary, whereas the sync-mirror variant does not.

Before using this command to create a SnapMirror relationship between Vservers, you typically create a source and destination Vserver using the **vserver create** command. The source Vserver should be of subtype **default** and the destination Vserver of subtype **dp-destination**. Also, before creating the relationship between Vservers, you must setup Vserver peer by using the **vserver peer create** command between the source and destination Vservers. A Vserver relationship cannot be created between two Vservers within the same cluster. The root volume of the destination Vserver will be read-write and data from the source Vserver's root volume will not be replicated. Therefore there will be no volume level relationship created between the root volumes of the two Vservers.

After creating the relationship, the destination Vserver must be initialized by using the **snapmirror initialize** command.

Before using this command to create a volume SnapMirror relationship, you typically create a source and destination volume using the **volume create** command. The source volume should be in the online state and a read-write (RW) type. The destination volume should be in the online state and a data protection (DP) type. For FlexGroup SnapMirror relationships, the source and destination FlexGroups must be spread over the same number of aggregates as specified in the **-aggr-list** parameter with the same number of constituents per aggregate as specified in the **-aggr-list-multiplier** parameter of the **volume create** command.

When a FlexGroup SnapMirror relationship is created, normally hidden relationships are also created for the constituent volumes. These relationships can be seen by using the **-expand** parameter of the **snapmirror show** command. Source information for these relationships can be seen using the **-expand** parameter of the **snapmirror list-destinations** command. Other SnapMirror commands are disabled for FlexGroup constituent relationships and FlexGroup constituent volumes.

If all systems involved are running Data ONTAP version 8.2 and later, a Vserver peering relationship must be set up using the **vserver peer create** command between the source and the destination Vservers to create a relationship between the source and destination volumes. To enable interoperability with Data ONTAP 8.1, if the source volume is on a storage system running clustered Data ONTAP 8.1, the cluster administrator can create a data protection relationship between the source and destination volumes without a Vserver peering relationship between the source and destination Vservers. These relationships are managed the same way as on Data ONTAP 8.1 and the "Relationship Capability" field, as shown in the output of the **snapmirror show** command, is set to "Pre 8.2".
**Note:** SnapMirror relationships, except load-sharing relationships, which are created between two volumes which are both on a storage system running Data ONTAP version 8.2 and later have the "Relationship Capability" field set to "8.2 and above".

Load-sharing mirrors must be confined to a single Vserver; they are not allowed to span Vservers. Load-sharing relationships are created with the "Relationship Capability" field set to "Pre 8.2" even if both the source and destination volumes are on a storage system running Data ONTAP version 8.2 and later. There is no "8.2 and above" implementation for load-sharing relationships.

A set of load-sharing mirrors can have one or more destination volumes. You create separate SnapMirror relationships between the common source volume and each destination volume to create the set of load-sharing mirrors.

The source or destination of a load-sharing relationship cannot be the source or destination of any other SnapMirror relationship.

After creating the relationship, the destination volume can be initialized using the `snapmirror initialize` command. The destination volumes in a set of load-sharing mirrors are initialized using the `snapmirror initialize-ls-set` command.

The `snapmirror create` command must be used from the destination Vserver or cluster.

### Parameters

```
-s {<vserver:><volume>|<[[cluster://vserver/]]volume>|<hostip:/lun/name>|<hostip:/share/share-name>} - Source Path
```

This parameter specifies the source endpoint of the SnapMirror relationship in one of four path formats. The normal format includes the names of the Vserver (vserver) and/or the volume (volume). To support relationships with "Relationship Capability" of "Pre 8.2", a format which also includes the name of the cluster (cluster) is provided. The "Pre 8.2" format cannot be used when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above". For SnapMirror relationships with an AltaVault source, the source endpoint is specified in the form `hostip:/share/share-name`. For SnapMirror relationships with a SolidFire source, the source endpoint is specified in the form `hostip:/lun/name`.

```
-destination-path {<vserver:><volume>|<[[cluster://vserver/]]volume>|<hostip:/lun/name>|<hostip:/share/share-name>} - Destination Path
```

This parameter specifies the destination endpoint of the SnapMirror relationship in one of four path formats. The normal format includes the names of the Vserver (vserver) and/or volume (volume). To support relationships with "Relationship Capability" of "Pre 8.2", a format which also includes the name of the cluster (cluster) is provided. The "Pre 8.2" format cannot be used when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above". For SnapMirror relationships with AltaVault destinations, the destination endpoint is specified in the form `hostip:/share/share-name`.
For relationships with SolidFire destinations, the destination endpoint is specified in the form `hostip:/lun/name`.

```
[-destination-cluster <Cluster name>] - Destination Cluster
```

Specifies the destination cluster of the SnapMirror relationship. If this parameter is specified, parameters `-destination-vserver` and `-destination-volume` must also be specified. This parameter is only applicable for relationships with "Relationship Capability" of "Pre 8.2". This parameter cannot be specified when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above".

```
-destination-vserver <vserver name> - Destination Vserver
```

Specifies the destination Vserver of the SnapMirror relationship. For relationships with volumes as endpoints, if this parameter is specified, parameters `-destination-volume` and for relationships with "Relationship Capability" of "Pre 8.2", `-destination-cluster` must also be specified. This parameter is not supported for relationships with non-Data ONTAP destination endpoints.

```
-destination-volume <volume name> - Destination Volume
```

Specifies the destination volume of the SnapMirror relationship. If this parameter is specified, parameters `-destination-vserver` and for relationships with "Relationship Capability" of "Pre 8.2", `-destination-cluster` must also be specified. This parameter is not supported for relationships with non-Data ONTAP destination endpoints.

```
[-type <snapmirrorType>] - Relationship Type
```

This parameter specifies the type of SnapMirror relationship that will be created. You can create a data protection (DP) relationship, an extended data protection (XDP) relationship, a transition data protection relationship between a Data ONTAP operating in 7-Mode system and a clustered Data ONTAP system (TDP), or a load-sharing (LS) relationship. The default value is XDP for all relationships except for Vserver DR relationships. FlexVol volumes and non-Data ONTAP endpoints support only XDP relationships. For FlexVol volume relationships, when DP is specified as the type, an XDP relationship will be created unless a relationship of type DP in the opposite direction already exists. In that case the new relationship will be of type DP.

```
[vserver <vserver name>] - Managing Vserver
```

If this optional parameter is specified, it designates the managing Vserver. The managing Vserver is authorized to use SnapMirror commands to manage the SnapMirror relationship. The `vserver` parameter is currently a reserved parameter.

```
[-schedule <text>] - SnapMirror Schedule
```

This optional parameter designates the name of the schedule which is used to update the SnapMirror relationship. If you do not designate a schedule, updates are not scheduled, so you must update the SnapMirror relationship manually using the `snapmirror update` command or, in the case of a set of load-sharing mirrors, using the `snapmirror update-ls-set` command.

**Note:** You define and name a schedule using the `job schedule cron create` command.

```
[-policy <sm_policy>] - SnapMirror Policy
```

This optional parameter designates the name of the SnapMirror policy which is associated with the SnapMirror relationship. For FlexVol volume relationships, the default policy when the data protection (DP) type is specified is `MirrorAllSnapshots` and the default policy when no type is specified or when the extended data protection (XDP) type is specified is `MirrorAndVault`. For FlexGroup volume relationships, the `MirrorAndVault` policy is applied. For SnapMirror relationships between SnapLock volumes, if no policy is specified the default policy `MirrorAllSnapshots` is applied. For relationships with a SolidFire endpoint, there is no default policy. For these relationships a policy as described below must be specified. This parameter is not applicable to relationships with "Relationship Capability" of "Pre 8.2".

In clustered Data ONTAP 8.2 data protection (DP) relationships were used for mirroring, while extended data protection (XDP) relationships were used for vaulting. In clustered Data ONTAP 8.3 extended data protection (XDP) relationships support two more use cases, mirroring and unified mirror-vault. The exact behavior of an
extended data protection (XDP) relationship is governed by the snapmirror policy associated with that relationship. In clustered Data ONTAP 8.3 the snapmirror policy has a new field type to indicate how the relationships with that policy will behave. The supported types are async-mirror (mirroring), vault (vaulting) and mirror-vault (unified mirroring and vault). For XDP relationships between a Data ONTAP source volume and an AltaVault destination endpoint, only policies of type vault are supported. For XDP relationships between a Data ONTAP source volume and a SolidFire destination endpoint, only policies of type async-mirror without an all_source_snapshots rule are supported. For XDP relationships between a SolidFire source endpoint and a Data ONTAP destination volume, only policies of type async-mirror without an all_source_snapshots rule, and policies of type mirror-vault are supported.

SnapMirror policies of type async-mirror associated with FlexVol volume relationships when relationship type DP is specified or when no relationship type is specified, must include the label all_source_snapshots. Refer to the man page for the snapmirror policy create command for more information.

Note: You define and name a policy using the snapmirror policy create command.

[-tries <unsigned32_or_unlimited>] - Tries Limit
This optional parameter specifies the maximum number of times to attempt each manual or scheduled transfer for a SnapMirror relationship. The default is eight times. The -tries parameter can be set to 0 to disable manual and scheduled updates for the SnapMirror relationship. This parameter is only applicable to relationships with "Relationship Capability" of "Pre 8.2". For relationships with "8.2 and above" capability, the tries limit is controlled by the value of tries in the SnapMirror policy that is associated with the relationship.

[-throttle | -k <throttleType>] - Throttle (KB/sec)
This optional parameter limits the network bandwidth used for transfers. It configures for the relationship the maximum rate (in Kbytes/sec) at which data can be transferred. If no throttle is configured, by default the SnapMirror relationship fully utilizes the network bandwidth available. You can also configure the relationship to fully use the network bandwidth available by explicitly setting the throttle to unlimited or 0. The minimum effective throttle value is four Kbytes/sec, so if you specify a throttle value between 1 and 4, it will be treated as 4. For FlexGroup volume relationships, the throttle value is applied individually to each constituent relationship. The -throttle parameter does not affect load-sharing mirrors and other SnapMirror relationships with "Relationship Capability" of "Pre 8.2" confined to a single cluster.

[-identity-preserve {true|false}] - Identity Preserve Vserver DR
Specifies whether or not the identity of the source Vserver is replicated to the destination Vserver of the Vserver SnapMirror relationship that will be created. If this parameter is set to true, the source Vserver's configuration will additionally be replicated to the destination. If the parameter is set to false, then only the source Vserver's volumes and RBAC configuration are replicated to the destination. This parameter is applicable only for SnapMirror relationships with Vserver endpoints. The default value is false.

[-is-auto-expand-enabled {true|false}] - Is Auto Expand Enabled
This optional parameter specifies whether or not a FlexGroup SnapMirror relationship and its destination FlexGroup volume should be auto-expanded if the source FlexGroup volume is expanded. This parameter is supported only for FlexGroup SnapMirror relationships. The default value is true.

Examples
To create an extended data protection relationship between the source endpoint vs1.example.com:dept_eng, and the destination endpoint vs2.example.com:dept_eng_dp_mirror2, with the default policy of MirrorAndVault, type the following command:

```
vs2.example.com:~> snapmirror create -destination-path vs2.example.com:dept_eng_dp_mirror2 -source-path vs1.example.com:dept_eng
```
To create an extended data protection relationship between the source FlexGroup vs1.example.com:fg_src and the destination FlexGroup vs2.example.com:fg_dst, with the default policy of MirrorAndVault, type the following command:

```
vs2.example.com::> snapmirror create -destination-path vs2.example.com:fg_dst -source-path vs1.example.com:fg_src
```

To create a synchronous SnapMirror relationship between the source Flexvol vs1.example.com:vol_log, and the destination Flexvol vs2.example.com:vol_log_sync_dp when the source cluster is running ONTAP 9.5 or above, type the following command:

```
vs2.example.com::> snapmirror create -destination-path vs2.example.com:vol_log_sync_dp -source-path vs1.example.com:vol_log -policy Sync
```

To create a strict synchronous SnapMirror relationship between the source Flexvol vs1.example.com:vol_log, and the destination Flexvol vs2.example.com:vol_log_sync_dp when the source cluster is running ONTAP 9.5 or above, type the following command:

```
vs2.example.com::> snapmirror create -destination-path vs2.example.com:vol_log_sync_dp -source-path vs1.example.com:vol_log -policy StrictSync
```

To create a data protection mirror between the source endpoint cluster1://vs1.example.com/dept_eng, and the destination endpoint cluster2://vs2.example.com/dept_eng_dp_mirror2 when the source cluster is running Data ONTAP 8.1 software, type the following command:

```
cluster2::> snapmirror create -destination-path cluster2://vs2.example.com/dept_eng_dp_mirror2 -source-path cluster1://vs1.example.com/dept_eng -type DP
```

To create a load-sharing mirror between the source endpoint cluster1://vs1.example.com/mkt1, and the destination endpoint cluster1://vs1.example.com/mkt1_ls1 with the schedule named 5min used to update the relationship, type the following command:

```
crcluster1::> snapmirror create -destination-path cluster1://vs1.example.com/mkt1_ls1 -source-path cluster1://vs1.example.com/mkt1 -type LS -schedule 5min
```

To create a SnapMirror relationship between the source Vserver vs1.example.com, and the destination Vserver dvsl.example.com with the schedule named hourly used to update the relationship, type the following command:

```
crcluster2::> snapmirror create -destination-path dvsl.example.com -source-path vs1.example.com -type LS -schedule hourly
```

To create an extended data protection (XDP) relationship between the Data ONTAP source endpoint vs1.example.com::data_ontap_vol, and the AltaVault destination endpoint 10.0.0.11:/share/share1, type the following command:

```
cluster2::> snapmirror create -destination-path 10.0.0.11:/share/share1 -source-path vs1.example.com::data_ontap_vol -type DP
```
To create an extended data protection (XDP) relationship between the SolidFire source endpoint 10.0.0.12:/lun/0001, and the Data ONTAP destination endpoint vs2.example.com:data_ontap_vol2, type the following command:

```
vs2.example.com::> snapmirror create -source-path 10.0.0.12:/lun/0001 -destination-path vs2.example.com:/data_ontap_vol2 -type XDP -policy MirrorLatest
```

Under PVR control to create a SnapMirror synchronous Consistency Group relationship with the following attributes:

- It is between the source Consistency Group `cg_src` in Vserver vs1.example.com, and the destination Consistency Group `cg_dst` in Vserver vs2.example.com.
- It has item mappings between `lun1` and `lun2` on volume `srcvol` and `lun1` and `lun2` on volume `dstvol`.
- It uses a policy named `SmgrSync` that has a policy type of `smgr-mirror` that the user has previously created.

Type the following command:

```
vs2.example.com::> snapmirror create -destination-path vs2.example.com:/cg/cg_dst -source-path vs1.example.com:/cg/cg_src -type XDP -policy SmgrSync -cg-item-mappings /vol/srcvol/lun1:@/vol/dstvol/lun1, /vol/srcvol/lun2:@/vol/dstvol/lun2
```

Under PVR control to create a new item mapping between `lun3` on volume `srcvol` and `lun3` on volume `dstvol` in the existing SnapMirror synchronous Consistency Group relationship that was created above, type the following command:

```
vs2.example.com::> snapmirror create -destination-path vs2.example.com:/cg/cg_dst -source-path vs1.example.com:/cg/cg_src -type XDP -policy SmgrSync -cg-item-mappings /vol/srcvol/lun3:@/vol/dstvol/lun3
```

snapmirror delete

Delete a SnapMirror relationship

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

**Description**

The `snapmirror delete` command removes the SnapMirror relationship between a source endpoint and a destination endpoint. The destination endpoint can be a Vserver, a volume, or a non-Data ONTAP endpoint. The Vservers, volumes and non-Data ONTAP destinations are not destroyed and Snapshot copies on the volumes are not removed.

For relationships with SolidFire endpoints, the SnapMirror source commands `snapmirror release` and `snapmirror list-destinations` are not supported. Therefore, Snapshot copies that are locked by SnapMirror on the source container cannot be cleaned up using the `snapmirror release` command. If the source container is a Data ONTAP volume, in order to reclaim space captured in the base Snapshot copy on the volume, issue a `snapshot delete` command specifying the `-ignore-owners` parameter in diag privilege level. To reclaim space captured in a Snapshot copy locked by SnapMirror on a SolidFire system, refer to SolidFire documentation.

The `snapmirror delete` command fails if a SnapMirror transfer for the SnapMirror relationship is in progress for relationships with "**Relationship Capability**" of "Pre 8.2". For relationships with "8.2 and above" capability the delete will succeed even if a transfer is in progress and the transfer will ultimately stop.

A set of load-sharing mirrors can contain multiple destination volumes, each destination volume having a separate SnapMirror relationship with the common source volume. When used on one of the SnapMirror relationships from the set of load-sharing mirrors, the `snapmirror delete` command deletes the specified SnapMirror relationship from the set of load-sharing mirrors.

The `snapmirror delete` command preserves the read-write or read-only attributes of the volumes of a SnapMirror relationship after the relationship is deleted. Therefore, a read-write volume that was the source of a SnapMirror relationship retains its read-write attributes, and a data protection volume or a load-sharing volume that was a destination of a SnapMirror relationship retains its read-only attributes. Similarly, the `subtype` attribute of source and destination Vservers is not modified when a Vserver SnapMirror relationship is deleted.

**Note:** When a SnapMirror relationship from a set of load-sharing mirrors is deleted, the destination volume becomes a data protection volume and retains the read-only attributes of a data protection volume.

For relationships with a policy of type `strict-sync-mirror` or `sync-mirror`, the relationship must be *Quiesced* before it can be deleted.

This command is supported for SnapMirror relationships with the field "**Relationship Capability**" showing as either "8.2 and above" or "Pre 8.2" in the output of the `snapmirror show` command.

For relationships with "**Relationship Capability**" of "8.2 and above", the `snapmirror delete` command must be used from the destination Vserver or cluster. The SnapMirror relationship information is deleted from the destination Vserver, but no cleanup or deletion is performed on the source Vserver. The `snapmirror release` command must be issued on the source Vserver to delete the source relationship information.

For relationships with "**Relationship Capability**" of "Pre 8.2", you can use this command from the source or from the destination cluster. When used from the destination cluster, the SnapMirror relationship information on the source and destination clusters is deleted. When used from the source cluster, only the SnapMirror relationship information on the source cluster is deleted.
Parameters

\{-source-path \-S \{-source-cluster \-source-vserver \-source-volume \} \} - Source Path

This parameter specifies the source endpoint of the SnapMirror relationship in one of four path formats. The normal format includes the names of the Vserver (vserver) and/or the volume (volume). To support relationships with "Relationship Capability" of "Pre 8.2", a format which also includes the name of the cluster (cluster) is provided. The "Pre 8.2" format cannot be used when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above". For SnapMirror relationships with an AltaVault source, the source endpoint is specified in the form hostip:/share/share-name. For SnapMirror relationships with a SolidFire source, the source endpoint is specified in the form hostip:/lun/name.

\{-source-cluster \{Cluster name\}\} - Source Cluster

Specifies the source cluster of the SnapMirror relationship. If this parameter is specified, the \-source-vserver and \-source-volume parameters must also be specified. This parameter is only applicable for relationships with "Relationship Capability" of "Pre 8.2". This parameter cannot be specified when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above".

\{-source-vserver \{vserver name\}\} - Source Vserver

Specifies the source Vserver of the SnapMirror relationship. For relationships with volumes as endpoints, if this parameter is specified, parameters \-source-volume and for relationships with "Relationship Capability" of "Pre 8.2", \-source-cluster must also be specified. This parameter is not supported for relationships with non-Data ONTAP source endpoints.

\{-source-volume \{volume name\}\} - Source Volume

Specifies the source volume of the SnapMirror relationship. If this parameter is specified, parameters \-source-vserver and for relationships with "Relationship Capability" of "Pre 8.2", \-source-cluster must also be specified. This parameter is not supported for relationships with non-Data ONTAP source endpoints.

\{-destination-path \{-destination-cluster \-destination-vserver \-destination-volume \} \} - Destination Path

This parameter specifies the destination endpoint of the SnapMirror relationship in one of four path formats. The normal format includes the names of the Vserver (vserver) and/or volume (volume). To support relationships with "Relationship Capability" of "Pre 8.2", a format which also includes the name of the cluster (cluster) is provided. The "Pre 8.2" format cannot be used when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above". For SnapMirror relationships with AltaVault destinations, the destination endpoint is specified in the form hostip:/share/share-name. For relationships with SolidFire destinations, the destination endpoint is specified in the form hostip:/lun/name.

\{-destination-cluster \{Cluster name\}\} - Destination Cluster

Specifies the destination cluster of the SnapMirror relationship. If this parameter is specified, parameters \-destination-vserver and \-destination-volume must also be specified. This parameter is only applicable for relationships with "Relationship Capability" of "Pre 8.2". This parameter cannot be specified when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above".

\-destination-vserver \{vserver name\} - Destination Vserver

Specifies the destination Vserver of the SnapMirror relationship. For relationships with volumes as endpoints, if this parameter is specified, parameters \-destination-volume and for relationships with "Relationship Capability" of "Pre 8.2", \-destination-cluster must also be specified. This parameter is not supported for relationships with non-Data ONTAP destination endpoints.
-destination-volume <volume name> - Destination Volume

Specifies the destination volume of the SnapMirror relationship. If this parameter is specified, parameters -
destination-vserver and for relationships with "Relationship Capability" of "Pre 8.2", -
destination-cluster must also be specified. This parameter is not supported for relationships with non-
Data ONTAP destination endpoints.

[-force | -f [true]] - Force

If specified, the delete proceeds even if it cannot clean up all artifacts of the relationship.

[-foreground | -w [true]] - Foreground Process

This specifies whether the operation runs as a foreground process. If this parameter is specified, the default
setting is true (the operation runs in the foreground). When set to true, the command will not return until
the process completes. This parameter is only applicable to relationships with "Relationship
Capability" of "Pre 8.2".

Examples

To delete the SnapMirror relationship with the destination endpoint vs2.example.com:dept_eng_dp_mirror4, type
the following command:

```
vs2.example.com::> snapmirror delete -destination-path
    vs2.example.com:dept_eng_dp_mirror4
```

For relationships with "Relationship Capability" of "Pre 8.2", to delete the SnapMirror relationship with the
destination endpoint cluster2://vs2.example.com/dept_eng_dp_mirror4, type the following command:

```
cluster2::> snapmirror delete -destination-path
    cluster2://vs2.example.com/dept_eng_dp_mirror4
```

To delete the SnapMirror relationship with destination endpoint dvs1.example.com:, type the following command:

```
cluster2::> snapmirror delete -destination-path
    dvs1.example.com:
```

Under PVR control to delete the synchronous SnapMirror Consistency Group relationship with the destination
Consistency Group cg_dst in Vserver vs2.example.com and all item mappings, type the following command:

```
vs2.example.com::> snapmirror delete -destination-path
    vs2.example.com:/cg/cg_dst
```

Under PVR control to delete the item mapping between lun3 on volume srcvol and lun3 on volume dstvol in the
SnapMirror synchronous Consistency Group relationship with the destination Consistency Group cg_dst in Vserver
vs2.example.com, type the following command:

```
vs2.example.com::> snapmirror delete -destination-path
    vs2.example.com:/cg/cg_dst
    -cg-item-mappings /vol/srcvol/lun3:/vol/dstvol/lun3
```

snapmirror initialize

Start a baseline transfer

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description

The snapmirror initialize command initializes the destination Vserver, volume or a non-Data ONTAP endpoint of a SnapMirror relationship. The command behaves differently between data protection (DP), extended data protection (XDP) and load-sharing (LS) relationships.

If you specify a sync-mirror or strict-sync-mirror type policy, the snapmirror initialize command creates and initializes a synchronous relationship and brings it InSync, providing zero RPO data protection.

For data protection (DP) and extended data protection (XDP) relationships, the snapmirror initialize command initializes the destination volume.

For load-sharing (LS) relationships, the snapmirror initialize command initializes a new load-sharing mirror in an existing set of load-sharing mirrors. If the command finishes before the start of a scheduled or manual transfer of the set of load-sharing mirrors, the load-sharing mirror is up to date with the set of load-sharing mirrors; otherwise, the load-sharing mirror will be brought up to date at the next scheduled or manual transfer of the set of load-sharing mirrors.

The initial transfer to an empty destination volume is called a baseline transfer. During a baseline transfer for a data protection (DP) or extended data protection (XDP) relationship, the snapmirror initialize command takes a Snapshot copy on the source volume to capture the current image of the source volume. For data protection relationships, the snapmirror initialize command transfers all of the Snapshot copies up to and including the Snapshot copy created by it from the source volume to the destination volume. For extended data protection (XDP) relationships, the snapmirror initialize command behavior depends on the snapmirror policy associated with the relationship. If the policy type is async-mirror then depending on the rules in the policy it can transfer either all the Snapshot copies up to and including the Snapshot copy created by it or only the Snapshot copy created by it from the source volume to the destination volume. For extended data protection (XDP) relationships with policy type vault or mirror-vault the snapmirror initialize transfers only the Snapshot copy created by it.

After the snapmirror initialize command successfully completes, the last Snapshot copy transferred is made the exported Snapshot copy on the destination volume.

You can use the snapmirror initialize command to initialize a specific load-sharing mirror that is new to the set of load-sharing mirrors. An initialize of the new load-sharing mirror should bring it up to date with the other up-to-date destination volumes in the set of load-sharing mirrors.

Note: Using the snapmirror initialize command to initialize a set of load-sharing mirrors will not work. Use the snapmirror initialize-ls-set command to initialize a set of load-sharing mirrors.

If a SnapMirror relationship does not already exist, that is, the relationship was not created using the snapmirror create command, the snapmirror initialize command will implicitly create the SnapMirror relationship, with the same behaviors as described for the snapmirror create command before initializing the relationship. This implicit create feature is not supported for Vservers.

This command is supported for SnapMirror relationships with the field "Relationship Capability" showing as either "8.2 and above" or "Pre 8.2" in the output of the snapmirror show command.

For relationships with "Relationship Capability" of "8.2 and above", you can track the progress of the operation using the snapmirror show command.

For relationships with "Relationship Capability" of "Pre 8.2", a job will be spawned to operate on the SnapMirror relationship, and the job id will be shown in the command output. The progress of the job can be tracked using the job show and job history show commands.
The `snapmirror initialize` command must be used from the destination Vserver or cluster.

### Parameters

```bash
[-source-path | -S {<[vserver:][volume]>|<[cluster:][vserver:][volume]>|<hostip:/lun/name> | <hostip:/share/share-name>}]
```

**- Source Path**

This parameter specifies the source endpoint of the SnapMirror relationship in one of four path formats. The normal format includes the names of the Vserver (`vserver`) and/or the volume (`volume`). To support relationships with "Relationship Capability" of "Pre 8.2", a format which also includes the name of the cluster (`cluster`) is provided. The "Pre 8.2" format cannot be used when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above". For SnapMirror relationships with an AltaVault source, the source endpoint is specified in the form `hostip:/share/share-name`. For SnapMirror relationships with a SolidFire source, the source endpoint is specified in the form `hostip:/lun/name`.

```bash
[-source-cluster <Cluster name>]
```

**- Source Cluster**

Specifies the source cluster of the SnapMirror relationship. If this parameter is specified, the `--source-vserver` and `--source-volume` parameters must also be specified. This parameter is only applicable for relationships with "Relationship Capability" of "Pre 8.2". This parameter cannot be specified when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above".

```bash
[-source-vserver <vserver name>]
```

**- Source Vserver**

Specifies the source Vserver of the SnapMirror relationship. For relationships with volumes as endpoints, if this parameter is specified, parameters `--source-volume` and for relationships with "Relationship Capability" of "Pre 8.2", `--source-cluster` must also be specified. This parameter is not supported for relationships with non-Data ONTAP source endpoints.

```bash
[-source-volume <volume name>]
```

**- Source Volume**

Specifies the source volume of the SnapMirror relationship. If this parameter is specified, parameters `--source-vserver` and for relationships with "Relationship Capability" of "Pre 8.2", `--source-cluster` must also be specified. This parameter is not supported for relationships with non-Data ONTAP source endpoints.

```bash
[-destination-path {<[vserver:][volume]>|<[cluster:][vserver:][volume]>|<hostip:/lun/name> | <hostip:/share/share-name>}]
```

**- Destination Path**

This parameter specifies the destination endpoint of the SnapMirror relationship in one of four path formats. The normal format includes the names of the Vserver (`vserver`) and/or volume (`volume`). To support relationships with "Relationship Capability" of "Pre 8.2", a format which also includes the name of the cluster (`cluster`) is provided. The "Pre 8.2" format cannot be used when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above". For SnapMirror relationships with AltaVault destinations, the destination endpoint is specified in the form `hostip:/share/share-name`. For relationships with SolidFire destinations, the destination endpoint is specified in the form `hostip:/lun/name`.

```bash
[-destination-cluster <Cluster name>]
```

**- Destination Cluster**

Specifies the destination cluster of the SnapMirror relationship. If this parameter is specified, parameters `--destination-vserver` and `--destination-volume` must also be specified. This parameter is only applicable for relationships with "Relationship Capability" of "Pre 8.2". This parameter cannot be specified when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above".

```bash
[-destination-vserver <vserver name>]
```

**- Destination Vserver**

Specifies the destination Vserver of the SnapMirror relationship. For relationships with volumes as endpoints, if this parameter is specified, parameters `--destination-volume` and for relationships with "Relationship Capability" of "Pre 8.2", `--destination-cluster` must also be specified. This parameter is not supported for relationships with non-Data ONTAP destination endpoints.
-destination-volume <volume name> - Destination Volume

Specifies the destination volume of the SnapMirror relationship. If this parameter is specified, parameters -destination-vserver and for relationships with "Relationship Capability" of "Pre 8.2", -destination-cluster must also be specified. This parameter is not supported for relationships with non-Data ONTAP destination endpoints.

[-source-snapshot | -s <text>] - Source Snapshot

This optional parameter specifies the Snapshot copy that snapmirror initialize will use for the baseline transfer. For data protection (DP) relationships, the baseline transfer will include all of the Snapshot copies up to and including the specified Snapshot copy. For extended data protection (XDP) relationships, the snapmirror initialize command behavior depends on the snapmirror policy associated with the relationship. If the policy type is async-mirror then depending on the rules in the policy it can transfer either all the Snapshot copies up to and including the specified Snapshot copy or only the specified Snapshot copy from the source volume to the destination volume. For extended data protection (XDP) relationships with policy type vault or mirror-vault the snapmirror initialize transfers only the specified Snapshot copy. This parameter is not supported for SnapMirror Synchronous relationships and relationships with "Relationship Capability" of "Pre 8.2".

[-type <snapmirrorType>] - Snapmirror Relationship Type

Specifies the type of SnapMirror relationship if a relationship is implicitly created. This parameter is the same as the one used in the snapmirror create command.

[-policy <sm_policy>] - SnapMirror Policy

This optional parameter designates the name of the SnapMirror policy which is associated with the SnapMirror relationship. If you do not designate a policy, the current policy will be retained. This parameter is not applicable to relationships with "Relationship Capability" of "Pre 8.2".

Note: You define and name a policy using the snapmirror policy create command.

[-throttle | -k <throttleType>] - Throttle (KB/sec)

This optional parameter limits the network bandwidth used for the initialize transfer. It sets the maximum rate (in Kbytes/sec) at which data can be transferred during the operation. If this parameter is not specified, the throttle value configured for the relationship with the snapmirror create or snapmirror modify command will be used. To fully use the network bandwidth available, set the throttle value to unlimited or 0. The minimum throttle value is four Kbytes/sec, so if you specify a throttle value between 1 and 4, it will be treated as if you specified 4. For FlexGroup relationships, the throttle value is applied individually to each constituent relationship. For SnapMirror Synchronous relationships the throttle value is applicable only for asynchronous transfers performed as part of user-initiated operations. The -throttle parameter does not affect load-sharing transfers and transfers for other relationships with "Relationship Capability" of "Pre 8.2" confined to a single cluster.

[-transfer-priority (low|normal)] - Transfer Priority

This optional parameter specifies the priority at which the transfer runs. The default value for this parameter is the value in the SnapMirror policy associated with this relationship. This parameter is not applicable to relationships with a "Relationship Capability" of "Pre 8.2".

[is-auto-expand-enabled (true|false)] - Is Auto Expand Enabled

This optional parameter specifies whether or not a FlexGroup SnapMirror relationship and its destination FlexGroup should be auto-expanded if the source FlexGroup is expanded. This parameter is supported only for FlexGroup SnapMirror relationships. If this initialize is creating a new Snapmirror relationship, the default value is true. If it is not creating a new relationship, if a value is specified, it must match the current value for the existing relationship. If the parameter is not specified the existing value will be retained.

[-foreground | -w [true]] - Foreground Process

This specifies whether the operation runs as a foreground process. If this parameter is specified, the default setting is true (the operation runs in the foreground). When set to true, the command will not return until
the process completes. This parameter is only applicable to relationships with "Relationship Capability" of "Pre 8.2".

**Examples**

To start the initial transfer for the SnapMirror relationship with the destination endpoint `vs2.example.com:dept_eng_dp_mirror2` after the relationship has been created with the `snapmirror create` command, type the following command:

```bash
vs2.example.com::> snapmirror initialize -destination-path vs2.example.com:dept_eng_dp_mirror2
```

For relationships with "Relationship Capability" of "Pre 8.2", to start the initial transfer for the SnapMirror relationship with the destination endpoint `cluster2://vs2.example.com/dep_mkt_dp_mirror2` after the relationship has been created with the `snapmirror create` command, type the following command:

```bash
cluster2::> snapmirror initialize -destination-path cluster2://vs2.example.com/dept_eng_dp_mirror2
```

To create a data protection mirror relationship between the source endpoint `vs1.example.com:dept_mkt`, and the destination endpoint `vs2.example.com:dep_mkt_dp_mirror`, and start the initial transfer, type the following command:

```bash
vs2.example.com::> snapmirror initialize -destination-path vs.example.com2:dept_mkt_dp_mirror -source-path vs1.example.com:dept_mkt
```

To create a data protection mirror relationship between the source endpoint `cluster1://vs1.example.com/dept_mkt`, and the destination endpoint `cluster2://vs2.example.com/dep_mkt_dp_mirror`, and start the initial transfer when the source cluster is running Data ONTAP 8.1 software, type the following command:

```bash
cluster2::> snapmirror initialize -destination-path cluster2://vs2.example.com/dept_mkt_dp_mirror -source-path cluster1://vs1.example.com/dept_mkt
```

To create an extended data protection (XDP) relationship between the Data ONTAP source endpoint `vsl.example.com:data_ontap_vol`, and the AltaVault destination endpoint `10.0.0.11:/share/share1`, and start the initial transfer, type the following command:

```bash
vsl.example.com::> snapmirror initialize -destination-path 10.0.0.11:/share/share1 -source-path vsl.example.com:data_ontap_vol -type XDP
```

To start the initial transfer for the Vserver SnapMirror relationship with destination endpoint `dvs1.example.com: after the relationship was created with the `snapmirror create` command, type the following command:

```bash
cluster2::> snapmirror initialize -destination-path dvs1.example.com:
```

To initialize the SnapMirror Synchronous relationship between FlexVols `vol_log` and `vol_log_sync_dp` and bring it to InSync, after it is created using the `snapmirror create` command, type the following command:

```bash
vs2.example.com::> snapmirror initialize -destination-path vs2.example.com:vol_log_sync_dp
```
To create a strict SnapMirror Synchronous relationship between FlexVols `vol_log` and `vol_log_sync_dp`, to initialize it and bring it to InSync, type the following command:

```
vs2.example.com::> snapmirror initialize -destination-path vs2.example.com:vol_log_sync_dp -source-path vs1.example.com:vol_log -policy StrictSync
```

Under PVR control to create a SnapMirror synchronous Consistency Group relationship with the following attributes:

- It is between the source Consistency Group `cg_src` in Vserver `vs1.example.com`, and the destination Consistency Group `cg_dst` in Vserver `vs2.example.com`.
- It has item mappings between `lun1` and `lun2` on volume `srcvol` and `lun1` and `lun2` on volume `dstvol`.
- It uses a policy named SmgrSync that has a policy type of `smgr-mirror` that the user has previously created.

and initialize it and bring it InSync, type the following command:

```
vs2.example.com::> snapmirror initialize -destination-path vs2.example.com:/cg/cg_dst -source-path vs1.example.com:/cg/cg_src -type XDP -policy SmgrSync -cg-item-mappings /vol/srcvol/lun1:@/vol/dstvol/lun1, /vol/srcvol/lun2:@/vol/dstvol/lun2
```

Under PVR control to initialize the relationship with destination Consistency Group `cg_dst` in Vserver `vs2.example.com` that has been created with the `snapmirror create` command and bring it InSync, type the following command:

```
vs2.example.com::> snapmirror initialize -destination-path vs2.example.com:/cg/cg_dst
```

### snapmirror initialize-ls-set

Start a baseline load-sharing set transfer

**Availability:** This command is available to `cluster` and `Vserver` administrators at the `admin` privilege level.

**Description**

The `snapmirror initialize-ls-set` command initializes and updates a set of load-sharing mirrors. This command is usually used after the `snapmirror create` command is used to create a SnapMirror relationship for each of the destination volumes in the set of load-sharing mirrors. The initial transfers to empty load-sharing mirrors are baseline transfers done in
parallel. During a baseline transfer Data ONTAP takes a Snapshot copy on the source volume to capture the current image of the source volume and transfers all of the Snapshot copies on the source volume to each of the destination volumes.

After the `snapmirror initialize-ls-set` command successfully completes, the last Snapshot copy transferred is made the exported Snapshot copy on the destination volumes.

The parameter that identifies the set of load-sharing mirrors is the source volume. Data and Snapshot copies are transferred from the source volume to all up-to-date destination volumes in the set of load-sharing mirrors.

Use the `snapmirror initialize` command to add and initialize a new destination volume to an existing set of load-sharing mirrors.

**Note:** Even if the load-sharing set only has one mirror, you still need to use the `snapmirror initialize-ls-set` command to initialize the set. The `snapmirror initialize` command can only be used to initialize a new destination volume, if the load-sharing set has already been initialized.

This command is only supported for SnapMirror relationships with the field "Relationship Capability" showing as "Pre 8.2" in the output of the `snapmirror show` command.

**Parameters**

```
-sourcopath | -S {<vserver:/vserver/volume> | <cluster://vserver/volume> | <hostip:/lun/name> | <hostip:/share/share-name> | <source-path | -source-path | -S {<vserver:/vserver/volume> | <cluster://vserver/volume> | <hostip:/lun/name> | <hostip:/share/share-name> - Source Path
```

This parameter specifies the source endpoint of the SnapMirror relationship in one of four path formats. The normal format includes the names of the Vserver (vserver) and/or the volume (volume). To support relationships with "Relationship Capability" of "Pre 8.2", a format which also includes the name of the cluster (cluster) is provided. The "Pre 8.2" format cannot be used when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above". For SnapMirror relationships with an AltaVault source, the source endpoint is specified in the form `hostip:/share/share-name`. For SnapMirror relationships with a SolidFire source, the source endpoint is specified in the form `hostip:/lun/name`.

```
-foreground | -w [true] - Foreground Process
```

This specifies whether the operation runs as a foreground process. If this parameter is specified, the default setting is `true` (the operation runs in the foreground). When set to `true`, the command will not return until the process completes. This parameter is only applicable to relationships with "Relationship Capability" of "Pre 8.2".
Examples

To initialize the group of load-sharing mirrors for the source endpoint //vs1.example.com/dept_eng, type the following command:

```
cluster1::> snapmirror initialize-ls-set -source-path //vs1.example.com/dept_eng
```

**snapmirror list-destinations**

Display a list of destinations for SnapMirror sources

**Availability:** This command is available to `cluster` and `Vserver` administrators at the `admin` privilege level.

**Description**

The `snapmirror list-destinations` command displays information including the destination endpoints, the relationship status, and transfer progress, for SnapMirror relationships whose source endpoints are in the current Vserver if you are in a Vserver context, or the current cluster if you are in a cluster context.

The command might display several relationships that have the same source and destination endpoints, but have different relationship IDs. If this is the case, some of the information is stale. It corresponds to relationships that have been deleted on the destination Vserver or cluster, and have not been released yet on the source Vserver or source cluster.

The relationships and the information displayed are controlled by the parameters that you specify. If no parameters are specified, the command displays the following information associated with each SnapMirror relationship whose source endpoint is in the current Vserver if you are in a Vserver context, or the current cluster if you are in a cluster context:

- Source path
- Relationship Type
- Destination Path
- Relationship Status
- Transfer Progress
- Progress Last Updated
- Relationship ID

Note the following limitations on the information displayed by the `snapmirror list-destinations` command:

- The "Relationship Status" field is not valid after the node hosting the source volume joins the cluster quorum, until at least one transfer is performed on the SnapMirror relationship.
- "Transfer Progress" and "Progress Last Updated" fields are only valid if a Snapshot copy transfer is in progress.
- The "Relationship ID" field is not valid for Vserver SnapMirror relationships.
The "Relationship Status", "Transfer Progress", and "Progress Last Updated" fields are not valid for FlexGroup relationships, but they are valid for FlexGroup constituent relationships.

The `-instance` and `-fields` parameters are mutually exclusive and select the fields that are displayed. The `-instance` parameter if specified, displays detailed information about the relationships. The `-fields` parameter specifies what fields should be displayed. The other parameters of the snapmirror list-destinations command, select the SnapMirror relationships for which the information is displayed.

This command is not supported for SnapMirror relationships with non-Data ONTAP endpoints.

**Parameters**

```
([-fields <fieldname>, ...]
  If you specify the `-fields <fieldname>, ...` parameter, the command only displays the fields that you have specified.

[-instance]
  If you specify the `-instance` parameter, the command displays detailed information about all relationships selected.

([-source-path | -S {<vserver:[volume]> | <[cluster://vserver/]volume> | <hostip:/lun/name> | <hostip:/share/share-name>}] - Source Path
  Selects SnapMirror relationships that have a matching source path name.

[-source-vserver <vserver name>] - Source Vserver
  Selects SnapMirror relationships that have a matching source Vserver name.

[-source-volume <volume name>] - Source Volume
  Selects SnapMirror relationships that have a matching source volume name.

([-destination-path {<vserver:[volume]> | <[cluster://vserver/]volume> | <hostip:/lun/name> | <hostip:/share/share-name>}] - Destination Path
  Selects SnapMirror relationships that have a matching destination path name.

[-destination-vserver <vserver name>] - Destination Vserver
  Selects SnapMirror relationships that have a matching destination Vserver name.

[-destination-volume <volume name>] - Destination Volume
  Selects SnapMirror relationships that have a matching destination volume name.

[-relationship-id <UUID>] - Relationship ID
  Selects SnapMirror relationships that have a matching relationship identifier. This parameter is not supported for Vserver SnapMirror relationships.

[-type <snapmirrorType>] - Relationship Type
  Selects SnapMirror relationships that have a matching relationship type. Possible values are:
  - DP
  - XDP
  - RST

[-relationship-group-type {none | vserver | consistencygroup | flexgroup}] - Relationship Group Type
  Selects SnapMirror relationships that have a matching relationship group type. Possible values are:
  - none
  - vserver
  - flexgroup)
```
[–policy-type {vault|async-mirror|mirror-vault|strict-sync-mirror|sync-mirror}] - SnapMirror Policy Type

Selects SnapMirror relationships that have a matching SnapMirror policy type. Possible values are:

• async-mirror
• vault
• mirror-vault

[–status <mirror status>] - Relationship Status

Selects SnapMirror relationships that have a matching relationship status. Possible values are:

• Idle
• Transferring

This parameter is not supported for FlexGroup SnapMirror relationships, but it is supported for FlexGroup constituent relationships.

[–transfer-progress {<integer>[KB|MB|GB|TB|PB]}] - Transfer Progress

Selects SnapMirror relationships that have a matching transfer progress. This parameter is not supported for FlexGroup SnapMirror relationships, but it is supported for FlexGroup constituent relationships.

[–progress-last-updated {<MM/DD HH:MM:SS>}] - Timestamp of Last Progress Update

Selects SnapMirror relationships that have a matching transfer progress last updated timestamp. This parameter is not supported for FlexGroup SnapMirror relationships, but it is supported for FlexGroup constituent relationships.

[–source-volume-node <nodename>] - Source Volume Node Name

Selects SnapMirror relationships that have a matching source volume node name. For FlexGroup relationships, it is the node which owns the root constituent source volume. This parameter is not supported for Vserver SnapMirror relationships.

[–expand [true]] - Show Constituents of the Group

Specifies whether to display constituent relationships of Vserver and FlexGroup SnapMirror relationships. By default, the constituents are not displayed.

Examples

To display summary information about all relationships whose source endpoints are in the current cluster, type the following command:

```bash
cluster1::> snapmirror list-destinations
```

<table>

snapmirror show on page 683
**snapmirror modify**

Modify a SnapMirror relationship

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

**Description**

The `snapmirror modify` command allows you to change one or more properties of SnapMirror relationships. The key parameter that identifies any SnapMirror relationship is the destination endpoint. The destination endpoint can be a Vserver, a volume, or a non-Data ONTAP endpoint.

For load-sharing mirrors, a change to a property affects all of the SnapMirror relationships in the set of load-sharing mirrors. Destination volumes in a set of load-sharing mirrors do not have individual property settings.

Changes made by the `snapmirror modify` command do not take effect until the next manual or scheduled update of the SnapMirror relationship. Changes do not affect updates that have started and have not finished yet.

This command is supported for SnapMirror relationships with the field "Relationship Capability" showing as either "8.2 and above" or "Pre 8.2" in the output of the `snapmirror show` command.

The `snapmirror modify` command must be used from the destination Vserver or cluster.

**Parameters**

```
[-source-path] -S {<vserver:>[volume]|<[[cluster://]vserver/]volume>|<hostip:/lun/name>|<hostip:/share/share-name>]} - Source Path
```

This parameter specifies the source endpoint of the SnapMirror relationship in one of four path formats. The normal format includes the names of the Vserver (vserver) and/or the volume (volume). To support relationships with "Relationship Capability" of "Pre 8.2", a format which also includes the name of the cluster (cluster) is provided. The "Pre 8.2" format cannot be used when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above". For SnapMirror relationships with an AltaVault source, the source endpoint is specified in the form `hostip:/share/share-name`. For SnapMirror relationships with a SolidFire source, the source endpoint is specified in the form `hostip:/lun/name`.

```
[-source-cluster <Cluster name>] - Source Cluster
```

Specifies the source cluster of the SnapMirror relationship. If this parameter is specified, the `-source-vserver` and `-source-volume` parameters must also be specified. This parameter is only applicable for relationships with "Relationship Capability" of "Pre 8.2". This parameter cannot be specified when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above".

```
[-source-vserver <vserver name>] - Source Vserver
```

Specifies the source Vserver of the SnapMirror relationship. For relationships with volumes as endpoints, if this parameter is specified, parameters `-source-volume` and for relationships with "Relationship Capability" of "Pre 8.2", `-source-cluster` must also be specified. This parameter is not supported for relationships with non-Data ONTAP source endpoints.

```
[-source-volume <volume name>]] - Source Volume
```

Specifies the source volume of the SnapMirror relationship. If this parameter is specified, parameters `-source-vserver` and for relationships with "Relationship Capability" of "Pre 8.2", `-source-cluster` must also be specified. This parameter is not supported for relationships with non-Data ONTAP source endpoints.
This parameter specifies the destination endpoint of the SnapMirror relationship in one of four path formats. The normal format includes the names of the Vserver (vserver) and/or volume (volume). To support relationships with "Relationship Capability" of "Pre 8.2", a format which also includes the name of the cluster (cluster) is provided. The "Pre 8.2" format cannot be used when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above". For SnapMirror relationships with AltaVault destinations, the destination endpoint is specified in the form hostip:/share/share-name. For relationships with SolidFire destinations, the destination endpoint is specified in the form hostip:/lun/name.

-destination-cluster <Cluster name> - Destination Cluster

Specifies the destination cluster of the SnapMirror relationship. If this parameter is specified, parameters -destination-vserver and -destination-volume must also be specified. This parameter is only applicable for relationships with "Relationship Capability" of "Pre 8.2". This parameter cannot be specified when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above".

-destination-vserver <vserver name> - Destination Vserver

Specifies the destination Vserver of the SnapMirror relationship. For relationships with volumes as endpoints, if this parameter is specified, parameters -destination-volume and for relationships with "Relationship Capability" of "Pre 8.2", -destination-cluster must also be specified. This parameter is not supported for relationships with non-Data ONTAP destination endpoints.

-destination-volume <volume name> - Destination Volume

Specifies the destination volume of the SnapMirror relationship. If this parameter is specified, parameters -destination-vserver and for relationships with "Relationship Capability" of "Pre 8.2", -destination-cluster must also be specified. This parameter is not supported for relationships with non-Data ONTAP destination endpoints.

-vserver <vserver name> - Managing Vserver

If this optional parameter is specified, designates the managing Vserver. The managing Vserver is authorized to use some snapmirror commands to manage the SnapMirror relationship. The -vserver option is currently a reserved option.

-schedule <text> - SnapMirror Schedule

This optional parameter designates the name of the schedule which is used to update the SnapMirror relationship. If you do not designate a schedule, updates are not scheduled, so you must update the SnapMirror relationship manually using the snapmirror update command or, in the case of a set of load-sharing mirrors, using the snapmirror update-ls-set command.

Note: You define and name a schedule using the job schedule cron create command.

-policy <sm_policy> - SnapMirror Policy

This optional parameter designates the name of the snapmirror policy which is associated with the SnapMirror relationship. If you do not designate a policy, the current policy will be retained. Modification of the policy is not supported for relationships with a policy of type strict-sync-mirror or sync-mirror. If you want to use a different policy for SnapMirror Synchronous relationships, you need to delete the relationship and create it again with the new policy. This parameter is not applicable to relationships with "Relationship Capability" of "Pre 8.2".

Note: You define and name a policy using the snapmirror policy create command.

-tries <unsigned32_or_unlimited> - Tries Limit

This optional parameter specifies the maximum number of times to attempt each manual or scheduled transfer for a SnapMirror relationship. The default is eight times. The -tries parameter can be set to 0 to disable manual and scheduled updates for the SnapMirror relationship. This parameter is only applicable to
relationships with "Relationship Capability" of "Pre 8.2". For relationships with "8.2 and above" capability, the tries limit is controlled by the value of tries in the SnapMirror policy that is associated with the relationship.

\[-\text{throttle} \mid -k <\text{throttleType}>\] - Throttle (KB/sec)

This optional parameter limits the network bandwidth used for transfers. It configures for the relationship the maximum rate (in Kbytes/sec) at which data can be transferred. If no throttle is configured, by default the SnapMirror relationship fully utilizes the network bandwidth available. You can also configure the relationship to fully use the network bandwidth available by explicitly setting the throttle to unlimited or 0. The minimum effective throttle value is four Kbytes/sec, so if you specify a throttle value between 1 and 4, it will be treated as 4. For FlexGroup volume relationships, the throttle value is applied individually to each constituent relationship. The \text{-throttle} parameter does not affect load-sharing mirrors and other SnapMirror relationships with "Relationship Capability" of "Pre 8.2" confined to a single cluster.

\[-\text{is-auto-expand-enabled} \{true|false\}\] - Is Auto Expand Enabled

This optional parameter specifies whether or not a FlexGroup SnapMirror relationship and its destination FlexGroup should be auto-expanded if the source FlexGroup is expanded. This parameter is supported only for FlexGroup SnapMirror relationships. If you do not specify the parameter, the current value of auto expand will be retained.

\[-\text{foreground} \mid -w [true]\] - Foreground Process

This specifies whether the operation runs as a foreground process. If this parameter is specified, the default setting is true (the operation runs in the foreground). When set to true, the command will not return until the process completes. This parameter is only applicable to relationships with "Relationship Capability" of "Pre 8.2".

\textbf{Examples}

To change the schedule to halfhour for the SnapMirror relationship with the destination endpoint vs2.example.com:dept_eng_dp_mirror2, type the following command:

```
vs2.example.com::> snapmirror modify -destination-path
                       vs2.example.com:dept_eng_dp_mirror2 -schedule halfhour
```

For relationships with "Relationship Capability" of "Pre 8.2", to change the schedule to halfhour for the SnapMirror relationship with the destination endpoint cluster2://vs2.example.com/dept_eng_dp_mirror2, type the following command:

```
cluster2::> snapmirror modify -destination-path
                   cluster2://vs2.example.com/dept_eng_dp_mirror2
                           -schedule halfhour
```

To change the schedule to halfhour for the Vserver SnapMirror relationship with destination endpoint dvs1.example.com:, type the following command:

```
cluster2::> snapmirror modify -destination-path
                  dvs1.example.com: -schedule halfhour
```

To change the policy associated with the synchronous SnapMirror Consistency Group relationship with the destination Consistency Group cg_dst in Vserver vs2.example.com to the policy Sync2, type the following command:

```
vs2.example.com::> snapmirror modify -destination-path
                        vs2.example.com:/cg/cg_dst -policy Sync2
```
snapmirror promote

Promote the destination to read-write

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description

The `snapmirror promote` command performs a failover to the destination volume of a SnapMirror relationship. This command changes the destination volume from a read-only volume to a read-write volume and makes the destination volume assume the identity of the source volume. The command then destroys the original source volume. The destination volume must be a load-sharing volume. Note that you can promote a load-sharing volume that has been left in read-write state by a previously failed promote operation.

Client accesses are redirected from the original source volume to the promoted destination volume. The view clients see on the promoted destination volume is the latest transferred Snapshot copy, which might lag behind the view clients had of the original source volume before the promote.

The SnapMirror relationship is always deleted as part of the promotion process.

It is possible that the original source volume is the source of multiple SnapMirror relationships. For such a configuration, the promoted destination volume becomes the new source volume of the other SnapMirror relationships.

This command is only supported for SnapMirror relationships with the field "Relationship Capability" showing as "Pre 8.2" in the output of the `snapmirror show` command.

The `snapmirror promote` command fails if a SnapMirror transfer is in progress for any SnapMirror relationship with "Relationship Capability" of "Pre 8.2" involving the original source volume. It does not fail if a SnapMirror transfer is in progress for a relationship with "Relationship Capability" of "8.2 and above".

Parameters

```
[-source-path | -S {<vserver:}\[volume]\]|<[[cluster:]]/vserver/\[volume]\]|<hostip:/lun/name>|<hostip:/share/share-name>\}] - Source Path

This parameter specifies the source endpoint of the SnapMirror relationship in one of four path formats. The normal format includes the names of the Vserver (vserver) and/or the volume (volume). To support relationships with "Relationship Capability" of "Pre 8.2", a format which also includes the name of the cluster (cluster) is provided. The "Pre 8.2" format cannot be used when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above". For SnapMirror relationships with an AltaVault source, the source endpoint is specified in the form hostip:/share/share-name. For SnapMirror relationships with a SolidFire source, the source endpoint is specified in the form hostip:/lun/name.

[-source-cluster <Cluster name>] - Source Cluster

Specifies the source cluster of the SnapMirror relationship. If this parameter is specified, the `-source-vserver` and `-source-volume` parameters must also be specified. This parameter is only applicable for relationships with "Relationship Capability" of "Pre 8.2". This parameter cannot be specified when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above".
```
[-source-vserver <vserver name>] - Source Vserver

Specifies the source Vserver of the SnapMirror relationship. For relationships with volumes as endpoints, if this parameter is specified, parameters -source-volume and for relationships with "Relationship Capability" of "Pre 8.2", -source-cluster must also be specified. This parameter is not supported for relationships with non-Data ONTAP source endpoints.

[-source-volume <volume name>] - Source Volume

Specifies the source volume of the SnapMirror relationship. If this parameter is specified, parameters -source-vserver and for relationships with "Relationship Capability" of "Pre 8.2", -source-cluster must also be specified. This parameter is not supported for relationships with non-Data ONTAP source endpoints.

[-destination-path {[vserver:][volume]|<[cluster://vserver]/volume>|<hostip:/lun/name>|<hostip:/share/share-name}>] - Destination Path

This parameter specifies the destination endpoint of the SnapMirror relationship in one of four path formats. The normal format includes the names of the Vserver (vserver) and/or volume (volume). To support relationships with "Relationship Capability" of "Pre 8.2", a format which also includes the name of the cluster (cluster) is provided. The "Pre 8.2" format cannot be used when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above". For SnapMirror relationships with AltaVault destinations, the destination endpoint is specified in the form hostip:/share/share-name. For relationships with SolidFire destinations, the destination endpoint is specified in the form hostip:/lun/name.

[-destination-cluster <Cluster name>] - Destination Cluster

Specifies the destination cluster of the SnapMirror relationship. If this parameter is specified, parameters -destination-vserver and -destination-volume must also be specified. This parameter is only applicable for relationships with "Relationship Capability" of "8.2 and above". This parameter cannot be specified when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above".

-destination-vserver <vserver name> - Destination Vserver

Specifies the destination Vserver of the SnapMirror relationship. For relationships with volumes as endpoints, if this parameter is specified, parameters -destination-volume and for relationships with "Relationship Capability" of "Pre 8.2", -destination-cluster must also be specified. This parameter is not supported for relationships with non-Data ONTAP destination endpoints.

-destination-volume <volume name> - Destination Volume

Specifies the destination volume of the SnapMirror relationship. If this parameter is specified, parameters -destination-vserver and for relationships with "Relationship Capability" of "Pre 8.2", -destination-cluster must also be specified. This parameter is not supported for relationships with non-Data ONTAP destination endpoints.

[-force | -f [true]] - Force

If this parameter is specified, the command proceeds without prompting for confirmation.

Examples

To promote a mirror named dept_eng_ls_mirror1 to be the source read-write volume for mirroring and client access, type the following command:

```
cluster1::> snapmirror promote -destination-path /vs1.example.com/dept_eng_ls_mirror1 -source-path /vs1.example.com/dept_eng -f true
```
**snapmirror protect**

**Start protection for volumes**

**Availability:** This command is available to cluster and Vserver administrators at the *admin* privilege level.

**Description**

The `snapmirror protect` command establishes SnapMirror protection for a list of volumes. For each volume, the command creates a data protection destination volume in the Vserver specified by the `-destination-vserver` parameter, creates an extended data protection (XDP) SnapMirror relationship, and starts the initialization of the SnapMirror relationship. This command must be used from the destination Vserver or cluster. This command is not supported for FlexGroup volume constituents, Vserver endpoints or non ONTAP endpoints.

**Parameters**

- `-path-list <{vserver:/volume}>|<[[cluster://vserver/]/volume>|<hostip:/lun/name>|<hostip:/share/share-name>>, ... - Path List`

  This parameter specifies the list of volumes to be protected. The list is a comma separated list of paths of the form `vserver:volume`, for example `vs1.example.com:dept_eng1`, `vs1.example.com:dept_eng2`

- `[-destination-vserver <vserver name>] - Destination Vserver`

  This parameter specifies the Vserver in which to create the destination volumes of the SnapMirror relationships.

- `[-schedule <text>] - SnapMirror Schedule`

  This optional parameter designates the name of the schedule which is used to update the SnapMirror relationships.

- `[-policy <sm_policy>] - SnapMirror Policy`

  This parameter designates the name of the SnapMirror policy which is associated with the SnapMirror relationships.

- `[-auto-initialize {true|false}] - Auto Initialize`

  This optional parameter specifies whether or not initializes of the SnapMirror relationships should be started after the relationships are created. The default value for this parameter is *true*.

- `[-destination-volume-prefix <text>] - Destination Volume Name Prefix`

  This optional parameter designates the prefix for the destination volume name. For example if the source path is of the form `vserver:volume` and the destination-volume-prefix specified is `prefix_` and no destination-volume-suffix is specified, then the destination volume name will be `prefix_volume_dst` or possibly `prefix_volume_1_dst` if a name conflict is encountered. If both prefix and suffix are specified as `prefix_` and `suffix`, then the destination volume name will be `prefix_volume_suffix` or `prefix_volume_1_suffix` if a name conflict is encountered.

- `[-destination-volume-suffix <text>] - Destination Volume Name Suffix`

  This optional parameter designates the suffix for the destination volume name. If you do not desgnate a suffix, a destination volume name with suffix `_dst` will be used. For example if the source path is of the form `vserver:volume`, and the suffix specified is `_DP`, the destination volume will be created with the name `volume_DP` or `volume_1_DP` if a name conflict is encountered. If both prefix and suffix are specified as `prefix_` and `suffix`, then the destination volume name will be `prefix_volume_suffix` or `prefix_volume_1_suffix` if a name conflict is encountered.
[support-tiering {true|false}] - Provision Destination Volumes on FabricPools

This optional parameter specifies whether or not FabricPools are selected when provisioning a FlexGroup during protection workflows. When this parameter is set to true, only FabricPools are used; when set to false, only non-FabricPools are used. Tiering support for a FlexGroup can be changed by moving all of the constituents to the required aggregates. The default value is false. This parameter is supported only for FlexGroups.

[[-tiering-policy {snapshot-only|auto|none|all}] - Destination Volume Tiering Policy

This optional parameter specifies the tiering policy to apply to the destination FlexGroup. This policy determines whether the user data blocks of a FlexGroup in a FabricPool will be tiered to the capacity tier when they become cold. FabricPool combines flash (performance tier) with an object store (external capacity tier) into a single aggregate. The default tiering policy is 'none' for a FlexGroup. The temperature of a FlexGroup block increases if it is accessed frequently and decreases when it is not.

The available tiering policies are:

• snapshot-only - This policy allows tiering of only the FlexGroup Snapshot copies not associated with the active file system. The default minimum cooling period is 2 days. The -tiering-minimum-cooling-days parameter can be used to override the default using the volume modify command after the destination FlexGroup has been created.

• auto - This policy allows tiering of both snapshot and active file system user data to the capacity tier. The default cooling period is 31 days. The -tiering-minimum-cooling-days parameter can be used to override the default using the volume modify command after the destination FlexGroup has been created.

• none - FlexGroup blocks will not be tiered to the capacity tier.

• backup - On DP FlexGroup this policy allows all transferred user data blocks to start in the capacity tier.

This parameter is supported only for FlexGroups.

Examples

To establish SnapMirror protection for the source volumes vs1.example.com:dept_eng1 and vs1.example.com:dept_eng2 using destination-vserver vs2.example.com and policy MirrorAllSnapshots type the following command:

```
vs2.example.com:/> snapmirror protect -path-list 
  vs1.example.com:dept_eng1,vs1.example.com:dept_eng2 -destination-vserver 
  vs2.example.com -policy MirrorAllSnapshots
```

snapmirror quiesce

Disable future transfers

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description

The snapmirror quiesce command disables future transfers for a SnapMirror relationship. If there is no transfer in progress, the relationship becomes "Quiesced".

If there is a transfer in progress, it is not affected, and the relationship becomes "Quiescing" until the transfer completes. If the current transfer aborts, it will be treated like a future transfer and will not restart.

If applied to a load-sharing (LS) SnapMirror relationship, all the relationships in the load-sharing set will be quiesced.
If applied to a relationship with a policy of type \textit{strict-sync-mirror} or \textit{sync-mirror}, any ongoing operation is aborted, and if the relationship is InSync, synchronous replication is stopped. If the replication policy type is "strict-sync-mirror", then the primary client I/O disruption is not enforced. A new common Snapshot copy is created if the relationship is InSync, unless a recent one exists. The relationship becomes "Quiescing" until these operations complete.

When a SnapMirror relationship is quiesced, it remains quiesced across reboots and fail-overs.

This command is supported for SnapMirror relationships with the field "Relationship Capability" showing as either "8.2 and above" or "Pre 8.2" in the output of the \texttt{snapmirror show} command.

The \texttt{snapmirror quiesce} command must be used from the destination Vserver or cluster.

The relationship must exist on the destination Vserver or cluster. When issuing \texttt{snapmirror quiesce}, you must specify the destination endpoint. The specification of the source endpoint of the relationship is optional.

**Parameters**

\begin{verbatim}
{ [-source-path | -S <[vserver:][volume]> | [[[cluster://vserver/]]volume>|<hostip:/lun/name> |<hostip:/share/share-name>]} - Source Path

This parameter specifies the source endpoint of the SnapMirror relationship in one of four path formats. The normal format includes the names of the Vserver (vserver) and/or the volume (volume). To support relationships with "Relationship Capability" of "Pre 8.2", a format which also includes the name of the cluster (cluster) is provided. The "Pre 8.2" format cannot be used when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above". For SnapMirror relationships with an AltaVault source, the source endpoint is specified in the form \texttt{hostip:/share/share-name}. For SnapMirror relationships with a SolidFire source, the source endpoint is specified in the form \texttt{hostip:/lun/name}.

[[-source-cluster <Cluster name>] - Source Cluster

Specifies the source cluster of the SnapMirror relationship. If this parameter is specified, the \texttt{-source-vserver} and \texttt{-source-volume} parameters must also be specified. This parameter is only applicable for relationships with "Relationship Capability" of "Pre 8.2". This parameter cannot be specified when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above".

[-source-vserver <vserver name>] - Source Vserver

Specifies the source Vserver of the SnapMirror relationship. For relationships with volumes as endpoints, if this parameter is specified, parameters \texttt{-source-volume} and for relationships with "Relationship Capability" of "Pre 8.2", \texttt{-source-cluster} must also be specified. This parameter is not supported for relationships with non-Data ONTAP source endpoints.

[-source-volume <volume name>] - Source Volume

Specifies the source volume of the SnapMirror relationship. If this parameter is specified, parameters \texttt{-source-vserver} and for relationships with "Relationship Capability" of "Pre 8.2", \texttt{-source-cluster} must also be specified. This parameter is not supported for relationships with non-Data ONTAP source endpoints.

{ [-destination-path | <[vserver:][volume]> | [[[cluster://vserver/]]volume>|<hostip:/lun/name> |<hostip:/share/share-name>]} - Destination Path

This parameter specifies the destination endpoint of the SnapMirror relationship in one of four path formats. The normal format includes the names of the Vserver (vserver) and/or volume (volume). To support relationships with "Relationship Capability" of "Pre 8.2", a format which also includes the name of the cluster (cluster) is provided. The "Pre 8.2" format cannot be used when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above". For SnapMirror relationships with AltaVault destinations, the destination endpoint is specified in the form \texttt{hostip:/share/share-name}. For relationships with SolidFire destinations, the destination endpoint is specified in the form \texttt{hostip:/lun/name}.

\end{verbatim}
[-destination-cluster <Cluster name>] - Destination Cluster

Specifies the destination cluster of the SnapMirror relationship. If this parameter is specified, parameters -
destination-vserver and -destination-volume must also be specified. This parameter is only
applicable for relationships with "Relationship Capability" of "Pre 8.2". This parameter cannot be
specified when operating in a Vserver context on relationships with "Relationship Capability" of "8.2
and above".

-destination-vserver <vserver name> - Destination Vserver

Specifies the destination Vserver of the SnapMirror relationship. For relationships with volumes as endpoints,
if this parameter is specified, parameters -destination-volume and for relationships with
"Relationship Capability" of "Pre 8.2", -destination-cluster must also be specified. This
parameter is not supported for relationships with non-Data ONTAP destination endpoints.

-destination-volume <volume name> - Destination Volume

Specifies the destination volume of the SnapMirror relationship. If this parameter is specified, parameters -
destination-vserver and for relationships with "Relationship Capability" of "Pre 8.2",
destination-cluster must also be specified. This parameter is not supported for relationships with non-
Data ONTAP destination endpoints.

---

Examples

To quiesce the SnapMirror relationship with the destination endpoint vs2.example.com:dept_eng_mirror2, type the
following command:

```
vs2.example.com::> snapmirror quiesce -destination-path
to vserver vs2.example.com:dept_eng_mirror2
```

For relationships with "Relationship Capability" of "Pre 8.2", to quiesce the SnapMirror relationship with the
destination endpoint cluster2://vs2.example.com/dept_eng_mirror2, type the following command:

```
cluster2::> snapmirror quiesce -destination-path
to vserver cluster2://vs2.example.com/dept_eng_mirror2
```

To quiesce the Vserver SnapMirror relationship with the destination endpoint dvs1.example.com:, type the following
command:

```
cluster2::> snapmirror quiesce -destination-path
to vserver dvs1.example.com:
```

Under PVR control to quiesce the synchronous SnapMirror Consistency Group relationship with the destination
Consistency Group cg_dst in Vserver vs2.example.com, type the following command:

```
vs2.example.com::> snapmirror quiesce -destination-path
to vserver vs2.example.com:/cg/cg_dst
```

snapmirror release

Remove source information for a SnapMirror relationship

**Availability:** This command is available to `cluster` and `Vserver` administrators at the `admin` privilege level.
Description

The *snapmirror release* command removes the relationship information from the source Vserver. The command also removes any Snapshot copy owner tags and any Snapshot copies which were created for the specified relationship from the source volumes. It does not destroy any volumes or Vservers. This command must be used from the source Vserver or cluster.

For relationships with a policy of type *strict-sync-mirror*, it additionally resumes primary volume access if the IO was restricted because the relationship was OutOfSync.

You can use the *snapmirror list-destinations* command to display source Vservers' relationship information. This information is populated during the first SnapMirror transfer, not when the *snapmirror create* command is issued.

This command is not supported for SnapMirror relationships with the field "Relationship Capability" showing as "Pre 8.2" in the output of the *snapmirror show* command.

This command is not supported for SnapMirror relationships with non-Data ONTAP endpoints.

The *snapmirror release* operation fails if a SnapMirror transfer for the SnapMirror relationship is in a data phase of the transfer.

Parameters

```
[-source-path | -S {<vserver:/][volume]> |<[[cluster://]vserver/][volume]> |<hostip:/lun/name>|<hostip:/share/share-name}>] - Source Path
```

Specifies the source endpoint of the SnapMirror relationship in one of two formats. The normal format includes the names of the Vserver (vserver), and/or volume (volume). A format which also includes the name of the cluster (cluster) is also provided for consistency with other snapmirror commands. The form of the pathname which includes the cluster name cannot be used when operating in a Vserver context.

```
[-source-vserver <vserver name>] - Source Vserver
```

Specifies the source Vserver of the SnapMirror relationship. For relationships with volumes as endpoints, if this parameter is specified, parameter *-source-volume* must also be specified.

```
[-source-volume <volume name>] - Source Volume
```

Specifies the source volume of the SnapMirror relationship. If this parameter is specified, parameter *-source-vserver* must also be specified.

```
[-destination-path {<vserver:/][volume]> |<[[cluster://]vserver/][volume]> |<hostip:/lun/name>|<hostip:/share/share-name}>] - Destination Path
```

Specifies the destination endpoint of the SnapMirror relationship in one of two formats. The normal format includes the names of the Vserver (vserver), and/or volume (volume). A format which also includes the name of the cluster (cluster) is also provided for consistency with other snapmirror commands. The form of the pathname which includes the cluster name cannot be used when operating in a Vserver context.

```
[-destination-vserver <vserver name>] - Destination Vserver
```

Specifies the destination Vserver of the SnapMirror relationship. For relationships with volumes as endpoints, if this parameter is specified, parameter *-destination-volume* must also be specified.

```
[-destination-volume <volume name>] - Destination Volume
```

Specifies the destination volume of the SnapMirror relationship. If this parameter is specified, parameter *-destination-vserver* must also be specified.

```
[-relationship-info-only [true]] - Remove relationship info only (skip cleanup of snapshots)
```

If this parameter is specified, the cleanup of Snapshot copies is bypassed and only the source relationship information is removed. It is recommended to specify this parameter only when the source volume is not accessible.

```
[-relationship-id <UUID>] - Relationship ID
```

This optional parameter specifies the relationship identifier of the relationship. It must be specified when information for more than one relationship with the same source and destination paths is present. This parameter is not supported for Vserver SnapMirror relationships.
[\texttt{-force}] -f \texttt{[true]} - Force

If this parameter is specified, the command proceeds without prompting for confirmation.

### Examples

To release the source information for the SnapMirror relationship with the destination endpoint `vs2.example.com:dept_eng_dp_mirror4`, type the following command:

```bash
vs1.example.com::> snapmirror release
-destination-path vs2.example.com:dept_eng_dp_mirror4
```

To release the source information for the SnapMirror relationship with the destination endpoint `vs2.example.com:dept_eng_dp_mirror4`, and relationship-id `5f91a075-6a72-11e1-b562-123478563412`, type the following command:

```bash
vs1.example.com::> snapmirror release
-destination-path vs2.example.com:dept_eng_dp_mirror4
-relationship-id 5f91a075-6a72-11e1-b562-123478563412
```

To release the source information for the SnapMirror relationship with the destination endpoint `dvs1.example.com`, type the following command:

```bash
cluster1::> snapmirror release
-destination-path dvs1.example.com:
```

Under PVR control to release the source information for the synchronous SnapMirror Consistency Group relationship with the destination Consistency Group `cg_dst` in Vserver `vs2.example.com`, type the following command:

```bash
vs2.example.com::> snapmirror release
-destination-path vs2.example.com:/cg/cg_dst
```

Under PVR control to release just the source information but not remove the Snapshot copies that might be needed for a subsequent resync for the synchronous SnapMirror Consistency Group relationship with the destination Consistency Group `cg_dst` in Vserver `vs2.example.com`, type the following command:

```bash
vs2.example.com::> snapmirror release
-destination-path vs2.example.com:/cg/cg_dst
-relationship-info-only true
```

### snapmirror restore

Restore a Snapshot copy from a source volume to a destination volume

**Availability:** This command is available to `cluster` and `Vserver` administrators at the `admin` privilege level.
Description
The `snapmirror restore` command restores the entire contents of a Snapshot copy or one or more files, LUNs or NVMe namespaces of a Snapshot copy from one volume to another volume.

The source of the restore can be a volume that is:

- the destination volume of a extended data protection (XDP) relationship
- the destination volume of a data protection (DP) relationship with "Relationship Capability" of "8.2 and above"
- a data-protection volume which is not the destination endpoint of any SnapMirror relationship
- a read-write volume.
- an AltaVault endpoint. In this case the destination must be an empty Data ONTAP volume.

The following cannot be used as either the source or destination volume of a restore:

- a volume that is the source or destination endpoint of a SnapMirror load-sharing relationship.
- a volume that is the destination endpoint of a SnapMirror relationship with the "Relationship Capability" of "Pre 8.2".
- a SolidFire endpoint.

A SnapMirror relationship of type `RST` is created from the source volume to the destination volume by the `snapmirror restore` command. This relationship lasts for the duration of the restore operation and is deleted when the command completes successfully.

The following paragraphs describe the behavior when restoring the entire contents of a Snapshot copy to a destination volume.

By default the `snapmirror restore` will copy the latest Snapshot copy from the source volume to the destination volume. A specific Snapshot copy can be selected with the `-source-snapshot` parameter.

Any quota rules defined for the destination volume are deactivated prior to restoring the entire contents of a Snapshot copy. Run the command `volume quota modify -vserver destination-volume-vserver -volume destination-volume-name -state on` to reactivate quota rules after the entire contents of the Snapshot copy have been restored.

If the destination volume is an empty data protection volume, the `snapmirror restore` command performs a baseline restore. For a baseline restore the following steps are performed:

- Create the `RST` SnapMirror relationship.
- The entire contents of the Snapshot copy selected to be restored are copied to the active file system of the destination volume.
- The destination volume is made read-write.
- The `RST` SnapMirror relationship is deleted.

If the destination volume is a read-write volume, an incremental restore is performed. The incremental restore fails if it cannot find a common Snapshot copy between the source and destination volumes. Restoring a Snapshot copy to an empty read-write volume is not supported. Incremental restore from a non-Data ONTAP endpoint to a Data ONTAP volume is not supported.

An incremental restore preserves all Snapshot copies on the destination volume but does not preserve changes to the active file system since the latest Snapshot copy. To preserve changes to the destination volume since the latest Snapshot copy use the `volume snapshot create` command. Restore is a disruptive operation so client access of the destination volume is not advised for the duration of the operation.

For an incremental restore the following steps are performed:

- Create the `RST` SnapMirror relationship.
The active file system of the destination volume is reverted to the latest Snapshot copy on the destination volume and the destination volume is made read-only.

This Snapshot copy is the exported Snapshot copy and it is the view to which clients are redirected when accessing the destination volume.

The contents of the Snapshot copy selected to be restored are copied to the active file system of the destination volume.

The destination volume is made read-write.

The RST SnapMirror relationship is deleted.

If `snapmirror restore` fails or is aborted, the RST relationship remains. Use the `snapmirror show` command with the destination volume name to display the reason for the error. An EMS is also generated when a failure occurs. There are two options to recover when restore fails or is aborted:

- Take corrective action suggested by the EMS and reissue the original command.
- Use the original command with `-clean-up-failure` to cancel the request.

When specifying `-clean-up-failure` to cancel an incremental restore request, the following steps are performed:

- If the Snapshot copy has not been restored to the destination volume, all data copied to the active file system by `snapmirror restore` to the destination volume is reverted.
- The destination volume is made read-write.
- The RST SnapMirror relationship is deleted.

When specifying `-clean-up-failure` to cancel a baseline restore request, the following steps are performed:

- If the Snapshot copy has been restored to the destination volume, the volume is made read-write.
- The RST SnapMirror relationship is deleted.

The following paragraphs describe the behavior and requirements when restoring one or more files, LUNs or NVMe namespaces to the destination volume.

The destination volume must be a read-write volume. Restoring files, LUNs or NVMe namespaces to a data protection volume is not supported. When restoring files, LUNs or NVMe namespaces the source and destination volumes are not required to have a common Snapshot copy. If a common Snapshot copy exists, an incremental restore is performed for those files, LUNs or NVMe namespaces being restored which exist in the common Snapshot copy.

The contents of the files, LUNs or NVMe namespaces to which data is being restored on the destination volume are not preserved by this command. To preserve the contents of the destination files, LUNs or NVMe namespaces, create a Snapshot copy on the destination volume prior to running this command. Client I/O is not allowed to a file, LUN or NVMe namespace to which data is being restored on the destination volume.

The `-source-snapshot` parameter is required when restoring files, LUNs or NVMe namespaces. It identifies the Snapshot copy on the source volume from which the files, LUNs or NVMe namespaces to be restored are copied. If all files, LUNs or NVMe namespaces to be restored do not exist in this Snapshot copy the command fails.

The source path for each file, LUN or NVMe namespace being restored is required. The source path of a file, LUN or NVMe namespace is from the root of the source Snapshot copy of the source volume. The file is restored to the same path on the destination volume unless an optional destination path is specified. The destination path is from the root of the destination volume. If a file, LUN or NVMe namespace to which data is being restored on the destination volume does not exist, the file, LUN or NVMe namespace is created. If any directory in the path of the file, LUN or NVMe namespace being restored does not exist on the destination volume, the command fails. Overwriting the contents of an existing file with the contents of a different file is supported. Similarly, overwriting the contents of an existing LUN or NVMe namespace with the contents of a different LUN or NVMe namespace is supported. However, overwriting a file with the contents of a LUN or NVMe namespace is not supported. Overwriting a LUN with the contents of a file or NVMe namespace is not supported. Overwriting an NVMe
namespace with the contents of a file or LUN is not supported. Client I/O is not allowed to all files, LUNs and NVMe namespaces to which data is being restored on the destination volume.

If quota rules have been defined for the destination volume, resource usage is updated during file restore, but limits of quota rules are not enforced. Therefore, resource limits might be exceeded during a file restore.

Multiple concurrent `snapmirror restore` commands, restoring one or more files, LUNs or NVMe namespaces to the same destination volume, are not supported. The destination volume of a `snapmirror restore` to which one or more files, LUNs or NVMe namespaces are being restored, can simultaneously be the source volume of a `snapmirror update`.

For a file, LUN or NVMe namespace restore the following steps are performed:

1. Create the RST SnapMirror relationship.
2. If any file, LUN or NVMe namespace being restored does not exist on the destination volume, create all such files, LUNs or NVMe namespaces.
3. Prevent client I/O to files, LUNs or NVMe namespaces to which data is being restored on the destination volume.
4. Revoke locks and space reservations held by NAS clients for files being restored.
5. Copy the contents of all source files, LUNs or NVMe namespaces to the corresponding file, LUN or NVMe namespace on the destination volume.
6. Allow client I/O to files, LUNs or NVMe namespaces to which data has been restored on the destination volume.
7. Delete the RST SnapMirror relationship.

**Note:** Some file restore operations require a Snapshot copy to be created. This Snapshot copy is temporary, it is deleted before the operation completes.

Since client I/O is not allowed to files, LUNs or NVMe namespaces being restored, client I/O to files, LUNs or NVMe namespaces being restored should be quiesced. Mapped LUNs or NVMe namespaces remain mapped throughout the operation. SAN clients do not need to rediscover a mapped LUN that has been restored. Restoring an NVMe namespace on top of another NVMe namespace with a different attribute relevant to NVMe protocol accessibility (like size) is not supported.

If `snapmirror restore` fails or is aborted, the RST relationship remains. Use the `snapmirror show` command with the destination volume to display the reason for the error. An EMS is also generated when a failure occurs. There are two options to recover when restore fails or is aborted:

1. Take corrective action suggested by the EMS and reissue the original command.
2. Use `snapmirror restore -clean-up-failure` along with specifying the destination volume to cancel the request.

When specifying `-clean-up-failure` to cancel a file restore request, the following steps are performed:

1. Any files to which client I/O is not allowed are removed.
2. Any Snapshot copy created for use during a file restore operation is deleted.
3. The RST SnapMirror relationship is deleted.

**Note:** LUNs to which client I/O is not allowed remain. For LUNs to which client I/O is not allowed, do one of the following:

1. Use the `snapmirror restore` command to restore data to the LUN. Once the command completes successfully, client I/O to the LUN is allowed.
2. Delete the LUN using the `lun delete` command with the `-force-fenced` parameter.

**Note:** Similarly, NVMe namespaces to which client I/O is not allowed remain. For NVMe namespaces to which client I/O is not allowed, do one of the following:
• Use the `snapmirror restore` command to restore data to the NVMe namespace. Once the command completes successfully, client I/O to the NVMe namespace is allowed.

• Delete the NVMe namespace using the `vserver nvme namespace delete` command with the `--skip-mapped-check` parameter.

The `snapmirror restore` command must be used from the destination Vserver or cluster.

**Parameters**

```bash
[-source-path -S {<[vserver:]volume>|<[[cluster://vserver/]volume>|<hostip:/lun/name>|<hostip:/share/share-name>]}] - Source Path
```

Specifies the source endpoint in one of three formats. The basic format includes the names of the Vserver (vserver) and volume (volume). A format which also includes the name of the cluster (cluster) is supported for consistency with other `snapmirror` commands. The form of the pathname which includes the cluster name is not valid when operating in a Vserver context. A non-Data ONTAP source endpoint (for example, AltaVault) can be specified in the form `hostip:/share/share-name`.

```bash
[-source-cluster <Cluster name>] - Source Cluster
```

Specifies the cluster in which the source volume resides. This parameter is not needed; it is provided for consistency with other `snapmirror` commands. If this parameter is specified, the `--source-vserver` and `--source-volume` parameters must also be specified. This parameter is not valid when operating in a Vserver context. This parameter is not supported if the source is a non-Data ONTAP endpoint.

```bash
[-source-vserver <vserver name>] - Source Vserver
```

Specifies the source Vserver of the SnapMirror relationship. If this parameter is specified, the `--source-volume` parameter must also be specified. This parameter is not supported if the source is a non-Data ONTAP endpoint.

```bash
[-source-volume <volume name>] - Source Volume
```

Specifies the source volume of the SnapMirror relationship. If this parameter is specified, the `--source-vserver` parameter must also be specified. This parameter is not supported if the source is a non-Data ONTAP endpoint.

```bash
[-destination-path {<[vserver:]volume>|<[[cluster://vserver/]volume>|<hostip:/lun/name>|<hostip:/share/share-name>]}] - Destination Path
```

Specifies the destination endpoint in one of two formats. The basic format includes the names of the Vserver (vserver) and volume (volume). A format that also includes the name of the cluster (cluster) is supported for consistency with other `snapmirror` commands. The form of the pathname which includes the cluster name is not valid when operating in a Vserver context.

```bash
[-destination-cluster <Cluster name>] - Destination Cluster
```

Specifies the cluster in which the destination volume resides. This parameter is not needed; it is provided for consistency with other `snapmirror` commands. If this parameter is specified, the `--destination-vserver` and `--destination-volume` parameters must also be specified. This parameter is only applicable for relationships with "Relationship Capability" of "Pre 8.2".

```bash
--destination-vserver <vserver name> - Destination Vserver
```

Specifies the destination Vserver. If this parameter is specified, the `--destination-volume` parameter must also be specified.

```bash
--destination-volume <volume name> - Destination Volume
```

Specifies the destination volume. If this parameter is specified, the `--destination-vserver` parameter must also be specified.
When restoring the entire contents of a Snapshot copy, this optional parameter identifies the Snapshot copy to be restored from the source volume to the destination volume. The default value is the latest snapshot on the source volume. When restoring one or more files, LUNs or NVMe namespaces from a Snapshot copy, this parameter is required.

This optional parameter limits the network bandwidth used for the restore transfer when the source and destination volumes belong to different clusters. It sets the maximum rate (in Kbytes/sec) at which data can be transferred between the clusters during the operation. To fully use the network bandwidth available between the clusters, set the throttle value to unlimited or 0. The minimum throttle value is four Kbytes/sec, so if you specify a throttle value between 1 and 4, it will be treated as if you specified 4.

This optional parameter specifies the priority at which the transfer runs. The default value for this parameter is normal.

The default behavior of restore is to preserve storage efficiency when possible. Use this optional parameter to turn off storage efficiency for data transferred over the wire and written to the destination volume.

Use this optional parameter to recover from an aborted or failed restore operation. Any temporary RST relationship is removed from the destination Vserver. An attempt is made to remove any temporary RST relationship from the source Vserver. If cleaning up an incomplete restore of the entire contents of a Snapshot copy and the destination volume was read-write prior to the failed or aborted restore operation, it is converted back to read-write if necessary, while removing all data transferred or copied during the restore operation. If cleaning up an incomplete restore of one or more files, LUNs or NVMe namespaces of a Snapshot copy, any file to which client I/O is not allowed is deleted.

Specifies the total number of attempts to transfer data in cases where a transfer is interrupted by an error that SnapMirror can recover from. The value of this parameter must be a positive integer or unlimited.

If this parameter is specified, the command proceeds without prompting for confirmation.

Specifies the files, LUNs or NVMe namespaces to be restored. The list can contain specifications for up to 8 files, LUNs or NVMe namespaces. Specification for each file, LUN or NVMe namespace consists of a source_path and an optional destination_path, and is of the form 'source_path[, @destination_path]'. source_path is required and is the path of the file from the source Snapshot copy, e.g. /dira/file1 or /lun1. The source path does not include the Snapshot name nor the source volume name. The path to each file to be restored in the active file system of the destination volume is the same as the path specified by source_path, unless an optional destination_path is specified. destination_path begins with the @ symbol followed by the path of the file from the root of the active file system of the destination volume, e.g. @/file1 or @/dira/lun1. Each source_path and destination_path is a separate entity in the list of paths. A destination_path is associated with the source_path that immediately precedes it. If this parameter is specified, -source-snapshot must also be specified. Examples:

```
/dira/file1
/dira/file1,@/dirb/file2
/dira/file1,@/dirb/file2,/dirc/file3
```
[use-network-compression [true]] - Use Network Compression

Use this optional parameter to use network compression for data transfer over the wire. This parameter is not supported for relationships with non-Data ONTAP endpoints.

### Examples

The following example does an incremental restore between the restore source volume vs2.example.com:dept_eng_dp_mirror2 and the restore destination volume vs1.example.com:dept_eng:

```bash
vs1.example.com::> snapmirror restore
    -destination-path vs1.example.com:dept_eng
    -source-path vs2.example.com:dept_eng_dp_mirror2
    -source-snapshot snap3
Warning: All data newer than Snapshot copy snap6 on volume
    vs1.example.com:dept_eng will be deleted.
Do you want to continue? {y|n}: y
[Job 34] Job is queued: snapmirror restore from source
    vs2.example.com:dept_eng_dp_mirror2 for the snapshot snap3.
vs1.example.com::>
```

The following example restores /file3 from the source Snapshot copy snap3 on the source volume vs2.example.com:dept_eng_dp_mirror2 to the active file system of the restore destination volume vs1.example.com:dept_eng:

```bash
vs1.example.com::> snapmirror restore
    -destination-path vs1.example.com:dept_eng
    -source-path vs2.example.com:dept_eng_dp_mirror2
    -source-snapshot snap3
    -file-list /file3
Warning: This command will overwrite any file on destination
    "vs1.example.com:dept_eng" that has the same path as any of
    the files to be restored.
Do you want to continue? {y|n}: y
[Job 35] Job is queued: snapmirror restore from source
    "vs2.example.com:dept_eng_dp_mirror2" for the snapshot snap3.
vs1.example.com::>
```

The following example restores /file3 from the source Snapshot copy snap3 on the source volume vs2.example.com:dept_eng_dp_mirror2 to /file3.new in the active file system of the restore destination volume vs1.example.com:dept_eng:

```bash
vs1.example.com::> snapmirror restore
    -destination-path vs1.example.com:dept_eng
    -source-path vs2.example.com:dept_eng_dp_mirror2
    -source-snapshot snap3
    -file-list /file3,@/file3.new
Warning: This command will overwrite any file on destination
    "vs1.example.com:dept_eng" that has the same path as any of
    the files to be restored.
Do you want to continue? {y|n}: y
[Job 36] Job is queued: snapmirror restore from source
    "vs2.example.com:dept_eng_dp_mirror2" for the snapshot snap3.
vs1.example.com::>
```

The following example restores /file1, /file2, and /file3 from the source Snapshot copy snap3 on the source volume vs2.example.com:dept_eng_dp_mirror2 respectively to /file1.new, /file2, and /file3.new in the active file system of the restore destination volume vs1.example.com:dept_eng:

```bash
vs1.example.com::> snapmirror restore
    -destination-path vs1.example.com:dept_eng
    -source-path vs2.example.com:dept_eng_dp_mirror2
    -source-snapshot snap3
    -file-list /file1,@/file1.new,/file2,/file3,@/file3.new
Warning: This command will overwrite any file on destination
    "vs1.example.com:dept_eng" that has the same path as any of
    the files to be restored.
```
The following example deletes data from an incomplete file restore, captured in a Snapshot copy which was later promoted to the active file system of a volume.

```
vs1.example.com::> snapmirror restore
   -destination-path vs1.example.com:dept_eng
   -file-restore-clean-up
Operation is queued: snapmirror restore with "-file-restore-clean-up"
on volume "vs1.example.com:dept_eng".
vs1.example.com::>
```

**Snapmirror resume**

Enable future transfers

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

**Description**

The `snapmirror resume` command enables future transfers for a SnapMirror relationship that has been quiesced.

If there is a scheduled transfer for the relationship, it will be triggered on the next schedule. If there is a restart checkpoint, it will be re-used if possible.

If applied on a load-sharing (LS) SnapMirror relationship, it enables future transfers for all the relationships in the load-sharing set.

If applied on a relationship with a policy of type `strict-sync-mirror` or `sync-mirror`, it enables future resync operations and initiates an Auto Resync.

When a quiesced SnapMirror relationship is resumed, future transfers remain enabled across reboots and fail-overs.

This command is supported for SnapMirror relationships with the field "Relationship Capability" showing as either "8.2 and above" or "Pre 8.2" in the output of the `snapmirror show` command.

The `snapmirror resume` command must be used from the destination Vserver or cluster.

The relationship must exist on the destination Vserver or cluster. When issuing `snapmirror resume`, you must specify the destination endpoint. The specification of the source endpoint of the relationship is optional.
Parameters

- **-source-path** 
  *<vserver:[volume]>|<[cluster://vserver]/volume>|<hostip:/lun/name>|<hostip:/share/share-name>*
  
  This parameter specifies the source endpoint of the SnapMirror relationship in one of four path formats. The normal format includes the names of the Vserver (vserver) and/or the volume (volume). To support relationships with "Relationship Capability" of "Pre 8.2", a format which also includes the name of the cluster (cluster) is provided. The "Pre 8.2" format cannot be used when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above". For SnapMirror relationships with an AltaVault source, the source endpoint is specified in the form hostip:/share/share-name. For SnapMirror relationships with a SolidFire source, the source endpoint is specified in the form hostip:/lun/name.

- **-source-cluster** 
  *<Cluster name>*
  
  Specifies the source cluster of the SnapMirror relationship. If this parameter is specified, the -source-vserver and -source-volume parameters must also be specified. This parameter is only applicable for relationships with "Relationship Capability" of "Pre 8.2". This parameter cannot be specified when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above".

- **-source-vserver** 
  *<vserver name>*
  
  Specifies the source Vserver of the SnapMirror relationship. For relationships with volumes as endpoints, if this parameter is specified, parameters -source-volume and for relationships with "Relationship Capability" of "Pre 8.2", -source-cluster must also be specified. This parameter is not supported for relationships with non-Data ONTAP source endpoints.

- **-source-volume** 
  *<volume name>*
  
  Specifies the source volume of the SnapMirror relationship. If this parameter is specified, parameters -source-vserver and for relationships with "Relationship Capability" of "Pre 8.2", -source-cluster must also be specified. This parameter is not supported for relationships with non-Data ONTAP source endpoints.

- **-destination-path** 
  *<vserver:[volume]>|<[cluster://vserver]/volume>|<hostip:/lun/name>|<hostip:/share/share-name>*
  
  This parameter specifies the destination endpoint of the SnapMirror relationship in one of four path formats. The normal format includes the names of the Vserver (vserver) and/or volume (volume). To support relationships with "Relationship Capability" of "Pre 8.2", a format which also includes the name of the cluster (cluster) is provided. The "Pre 8.2" format cannot be used when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above". For SnapMirror relationships with AltaVault destinations, the destination endpoint is specified in the form hostip:/share/share-name. For relationships with SolidFire destinations, the destination endpoint is specified in the form hostip:/lun/name.

- **-destination-cluster** 
  *<Cluster name>*
  
  Specifies the destination cluster of the SnapMirror relationship. If this parameter is specified, parameters -destination-vserver and -destination-volume must also be specified. This parameter is only applicable for relationships with "Relationship Capability" of "Pre 8.2". This parameter cannot be specified when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above".

- **-destination-vserver** 
  *<vserver name>*
  
  Specifies the destination Vserver of the SnapMirror relationship. For relationships with volumes as endpoints, if this parameter is specified, parameters -destination-volume and for relationships with "Relationship Capability" of "Pre 8.2", -destination-cluster must also be specified. This parameter is not supported for relationships with non-Data ONTAP destination endpoints.
-destination-volume <volume name> - Destination Volume

Specifies the destination volume of the SnapMirror relationship. If this parameter is specified, parameters -destination-vserver and for relationships with "Relationship Capability" of "Pre 8.2", -destination-cluster must also be specified. This parameter is not supported for relationships with non-Data ONTAP destination endpoints.

Examples

To re-enable future transfers for the SnapMirror relationship with the destination endpoint vs2.example.com:dept_eng_dp_mirror2 that has been previously quiesced, type the following command:

```
vs2.example.com::> snapmirror resume -destination-path vs2.example.com:dept_eng_dp_mirror2
```

To re-enable future transfers for the SnapMirror relationship with the destination endpoint cluster2://vs2.example.com/dept_eng_dp_mirror2 that has been previously quiesced, type the following command:

```
cluster2::> snapmirror resume -destination-path cluster2://vs2.example.com/dept_eng_dp_mirror2
```

To re-enable future transfers for the Vserver SnapMirror relationship with the destination endpoint dvs1.example.com: that has been previously quiesced, type the following command:

```
cluster2::> snapmirror resume -destination-path dvs1.example.com:
```

Under PVR control to re-enable future transfers and initiate an Auto Resync of the synchronous SnapMirror Consistency Group relationship with the destination Consistency Group cg_dst in Vserver vs2.example.com, type the following command:

```
vs2.example.com::> snapmirror resume -destination-path vs2.example.com:/cg/cg_dst
```

snapmirror resync

Start a resynchronize operation

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description

The snapmirror resync command establishes or reestablishes a mirroring relationship between a source and a destination endpoint. The endpoints can be Vservers, volumes or non-Data ONTAP endpoints that support SnapMirror. snapmirror resync for a SnapMirror relationship with volumes as endpoints is typically executed in the following cases:

- The destination mirror is broken (that is, the destination volume is a read-write volume and no longer a data protection mirror). After the snapmirror resync command completes, the destination volume is made a data protection mirror and the mirror can be manually updated or scheduled for updates.
• `snapmirror update` command failed because the required common Snapshot copy was deleted on the source volume.

• The volumes are the first and third endpoints in a cascade chain of relationships and they have a common Snapshot copy. In this case, `snapmirror resync` might implicitly create the SnapMirror relationship between them.

Attention: The `snapmirror resync` command can cause data loss on the destination volume because the command can remove the exported Snapshot copy on the destination volume.

The default behavior of the `snapmirror resync` command for volume relationships is defined as follows:

• Finds the most recent common Snapshot copy between the source and destination volumes, removes Snapshot copies on the destination volume that are newer than the common Snapshot copy and mounts the destination volume as a DP volume with the common Snapshot copy as the exported Snapshot copy.

• For data protection (DP) relationships, takes a Snapshot copy of the source volume to capture the current image and transfers Snapshot copies that are newer than the common Snapshot copy from the source volume to the destination volume. For extended data protection (XDP) relationships, transfers Snapshot copies newer than the common Snapshot copy according to the relationship policy, i.e., Snapshot copies will match rules associated with the policy as defined by the `snapmirror policy` commands. For relationships associated with `snapmirror policy` of type `async-mirror` and `mirror-vault` the `snapmirror resync` first takes a Snapshot copy of the source volume and includes it in the Snapshot copies selected for transfer.

• For a SnapLock Compliance volume in an XDP relationship with SnapMirror policy of type `async-mirror`, if SnapMirror resync operation detects data divergence between the common Snapshot copy and the AFS on the destination volume, the resync operation preserves the data changes in a locked Snapshot copy for the duration of the current volume expiry time. If the volume expiry time is in the past or has not been set, then the Snapshot copy is locked for a duration of 30 days. The common Snapshot copy is also locked for the same duration.

For Vserver SnapMirror relationships, a resync operation is typically executed when the relationship is broken-off, the `subtype` of the destination Vserver is `default` and the destination volumes are of type read-write. Once the command is queued, the `subtype` of the destination Vserver changes from `default` to `dp-destination`. A successful resync operation also makes the destination Vserver's volumes data protection volumes.

If the resync command is executed on a Vserver SnapMirror relationship, and the corresponding source and destination Vservers have volumes with volume level SnapMirror relationships, then the volume level SnapMirror relationships will be converted to volumes under the Vserver SnapMirror relationship. This conversion is supported only for source and destination Vservers which have been transitioned from a 7-Mode vFiler into a C-Mode Vserver. Some basic pre-requisites for the conversion are that the destination Vserver should be in a stopped state and all the destination Vserver volumes except the root volume should be in a volume level SnapMirror relationship with volumes of the source Vserver. The state of these volume level SnapMirror relationships should be Snapmirrored and status should be Idle.

`snapmirror resync` for a relationship with a policy of type `strict-sync-mirror` or `sync-mirror` is typically executed in the following case:

• The destination mirror is broken (that is, the destination volume is read-write and no longer read-only). After the `snapmirror resync` command completes, the destination volume changes to read-only and the relationship to InSync.

Note: The `snapmirror resync` command is typically not required to return a relationship that has fallen out of sync due to an error condition to InSync because SnapMirror has Auto Resync for synchronous relationships. When SnapMirror detects that the relationship has fallen out of sync for any reason other than a `snapmirror quiesce`, `snapmirror break` or `snapmirror delete` command was executed on the relationship, it will automatically initiate a resync operation.

The default behavior of the `snapmirror resync` command for relationships with a policy of type `strict-sync-mirror` or `sync-mirror` is defined as follows:

• Creates a Snapshot copy on the destination of the current image of the destination file system. This Snapshot copy becomes the exported Snapshot copy for the volume during the resync operation.

• Finds the most recent common Snapshot copy between the source and destination volumes. Performs a local rollback transfer to give the active file system the same data as the common Snapshot copy. It then loops through a sequence, creating
a Snapshot copy on the source volume, transferring the data captured in that Snapshot copy, creating a Snapshot copy of the data on the destination, and repeating until the relationship is close to InSync. After the last transfer, it enters cutover to bring the relationship to InSync.

- User-created Snapshot copies are not replicated by a resync operation.
- At the conclusion of the resync operation, the exported Snapshot copy on the destination is removed and the client will then see the active file system on the destination volume. The relationship will be InSync and periodic creation of common Snapshot copies will resume.

The `snapmirror resync` command supports an optional parameter "preserve". The parameter "preserve" is only supported for extended data protection (XDP) relationships. It is not supported for relationships with a non-Data ONTAP endpoint. It is not supported for relationships with a policy of type `strict-sync-mirror` and `sync-mirror`. When used, the parameter "preserve" changes the behavior of the `snapmirror resync` command. The changed behavior of the command can be described as follows:

- Finds the most recent common Snapshot copy between the source and destination volumes, preserves all Snapshot copies on the destination volume that are newer than the common Snapshot copy, and mounts the destination volume as a DP volume with the common Snapshot copy as the exported Snapshot copy.
- Performs a local rollback transfer to make a copy of the common Snapshot copy on the destination volume and establish it as the latest Snapshot copy on the destination volume. The command then transfers all Snapshot copies that are newer than the common Snapshot copy, from the source volume to the destination volume. The command only transfers Snapshot copies that match the relationship's policy, i.e., Snapshot copies will match rules associated with the policy as defined by the `snapmirror policy` commands.

If a SnapMirror relationship does not already exist, that is, the relationship was not created using the `snapmirror create` command, the `snapmirror resync` command will implicitly create the SnapMirror relationship, with the same behaviors as described for the `snapmirror create` command before resyncing it.

For Vservers, you must create SnapMirror relationships between Vservers by using the `snapmirror create` command before you run the `snapmirror resync` command. The snapmirror resync command does not implicitly create the relationship.

This command is supported for SnapMirror relationships with the field "Relationship Capability" showing as either "8.2 and above" or "Pre 8.2" in the output of the `snapmirror show` command.

For relationships with "Relationship Capability" of "8.2 and above", you can track the progress of the operation using the `snapmirror show` command.

For relationships with "Relationship Capability" of "Pre 8.2", a job will be spawned to operate on the SnapMirror relationship, and the job id will be shown in the command output. The progress of the job can be tracked using the `job show` and `job history show` commands.

The `snapmirror resync` command fails if the destination volume does not have a Snapshot copy in common with the source volume.

The `snapmirror resync` command does not work on load-sharing mirrors.

The `snapmirror resync` command must be used from the destination Vserver or cluster.

**Parameters**

```
[-source-path | -S {<vserver:>[volume]|<[[cluster://vserver/]|volume|<hostip:/lun/name|<hostip:/share/share-name>]}] - Source Path
```

This parameter specifies the source endpoint of the SnapMirror relationship in one of four path formats. The normal format includes the names of the Vserver (vserver) and/or the volume (volume). To support relationships with "Relationship Capability" of "Pre 8.2", a format which also includes the name of the cluster (cluster) is provided. The "Pre 8.2" format cannot be used when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above". For SnapMirror relationships with an AltaVault source, the source endpoint is specified in the form `hostip:/share/share-name`. For
SnapMirror relationships with a SolidFire source, the source endpoint is specified in the form `hostip:/lun/name`.

**[-source-cluster <Cluster name>] - Source Cluster**

Specifies the source cluster of the SnapMirror relationship. If this parameter is specified, the `-source-vserver` and `-source-volume` parameters must also be specified. This parameter is only applicable for relationships with "Relationship Capability" of "Pre 8.2". This parameter cannot be specified when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above".

**[-source-vserver <vserver name>] - Source Vserver**

Specifies the source Vserver of the SnapMirror relationship. For relationships with volumes as endpoints, if this parameter is specified, parameters `-source-volume` and for relationships with "Relationship Capability" of "Pre 8.2", `-source-cluster` must also be specified. This parameter is not supported for relationships with non-Data ONTAP source endpoints.

**[-source-volume <volume name>] - Source Volume**

Specifies the source volume of the SnapMirror relationship. If this parameter is specified, parameters `-source-vserver` and for relationships with "Relationship Capability" of "Pre 8.2", `-source-cluster` must also be specified. This parameter is not supported for relationships with non-Data ONTAP source endpoints.

**{ -destination-path {<[vserver:]volume>|<[[cluster://vserver/]volume>|<hostip:/lun/name>|<hostip:/share/share-name> ]} - Destination Path**

This parameter specifies the destination endpoint of the SnapMirror relationship in one of four path formats. The normal format includes the names of the Vserver (vserver) and/or volume (volume). To support relationships with "Relationship Capability" of "Pre 8.2", a format which also includes the name of the cluster (cluster) is provided. The "Pre 8.2" format cannot be used when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above". For SnapMirror relationships with AltaVault destinations, the destination endpoint is specified in the form `hostip:/share/share-name`. For relationships with SolidFire destinations, the destination endpoint is specified in the form `hostip:/lun/name`.

**[-destination-cluster <Cluster name>] - Destination Cluster**

Specifies the destination cluster of the SnapMirror relationship. If this parameter is specified, parameters `-destination-vserver` and `-destination-volume` must also be specified. This parameter is only applicable for relationships with "Relationship Capability" of "Pre 8.2". This parameter cannot be specified when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above".

**-destination-vserver <vserver name> - Destination Vserver**

Specifies the destination Vserver of the SnapMirror relationship. For relationships with volumes as endpoints, if this parameter is specified, parameters `-destination-volume` and for relationships with "Relationship Capability" of "Pre 8.2", `-destination-cluster` must also be specified. This parameter is not supported for relationships with non-Data ONTAP destination endpoints.

**-destination-volume <volume name> - Destination Volume**

Specifies the destination volume of the SnapMirror relationship. If this parameter is specified, parameters `-destination-vserver` and for relationships with "Relationship Capability" of "Pre 8.2", `-destination-cluster` must also be specified. This parameter is not supported for relationships with non-Data ONTAP destination endpoints.

**[-source-snapshot | -s <text>] - Source Snapshot**

This optional parameter specifies a Snapshot copy to transfer. The default behavior for a data protection relationship with a read-write source is that Data ONTAP creates a new Snapshot copy and uses it as the basis for determining what data are replicated; with this option, the specified Snapshot copy will be used instead. The default behavior for an extended data protection relationship depends on the relationship's policy type. For a data protection relationship, the specified Snapshot copy must be newer than the latest common Snapshot
copy. For an extended data protection relationship, the specified Snapshot copy can be newer or older than the common Snapshot copy. This parameter is not supported for relationships with "Relationship Capability" of "Pre 8.2".

\[<\text{snapmirrorType}>\] - SnapMirror Relationship Type

Specifies the type of SnapMirror relationship if a relationship is implicitly created. This parameter is the same as the one used in the \texttt{snapmirror create} command.

\[<\text{sm_policy}>\] - SnapMirror Policy

This optional parameter designates the name of the SnapMirror policy which is associated with the SnapMirror relationship. If you do not designate a policy, the current policy will be retained. This parameter is not applicable to relationships with "Relationship Capability" of "Pre 8.2".

**Note:** You define and name a policy using the \texttt{snapmirror policy create} command.

\[<true|false>|-f\] - Force

If this parameter is specified, the command proceeds without prompting for confirmation.

\[<\text{throttleType}>\] - Throttle (KB/sec)

This optional parameter limits the network bandwidth used for the resync transfer. It sets the maximum rate (in Kbytes/sec) at which data can be transferred during the operation. If this parameter is not specified, the throttle value configured for the relationship with the \texttt{snapmirror create} or \texttt{snapmirror modify} command will be used. To fully use the network bandwidth available, set the throttle value to \texttt{unlimited} or \texttt{0}. The minimum throttle value is four Kbytes/sec, so if you specify a throttle value between 1 and 4, it will be treated as if you specified 4. For FlexGroup relationships, the throttle value is applied individually to each constituent relationship. For relationships with a policy of type \texttt{strict-sync-mirror} or \texttt{sync-mirror}, the throttle value is applicable only for the asynchronous transfers of the resync operation. The \texttt{-throttle} parameter does not affect load-sharing transfers and transfers for other relationships with "Relationship Capability" of "Pre 8.2" confined to a single cluster.

\[<\text{low|normal}>\] - Transfer Priority

This optional parameter specifies the priority at which the transfer runs. The default value for this parameter is the value in the SnapMirror policy associated with this relationship. This parameter is not applicable to relationships with a "Relationship Capability" of "Pre 8.2".

\[<true|false>|-preserve\] - Preserve

This parameter is only supported for extended data protection (XDP) relationships with policies of type \texttt{vault}, \texttt{mirror-vault}. It is not supported for relationships with a policy of type \texttt{async-mirror} and data protection and load-sharing relationships. This parameter is not supported for relationships with non-Data ONTAP endpoints. It is not supported for relationships with a policy of type \texttt{strict-sync-mirror} and \texttt{sync-mirror}. When specified, it changes the behavior of the \texttt{snapmirror resync} command to preserve Snapshot copies on the destination volume that are newer than the latest common Snapshot copy. This parameter is not supported for relationships with "Relationship Capability" of "Pre 8.2".

\[<true|false>|-quick-resync\] - Quick Resync

This parameter is only supported for extended data protection (XDP) relationships. This parameter is not supported for relationships with non-Data ONTAP endpoints. It is not supported for relationships with a policy of type \texttt{strict-sync-mirror} and \texttt{sync-mirror}. Specifying this optional parameter reduces the resync time because the resync does not incur storage efficiency overhead before the transfer of new data. Specifying this parameter is recommended if the source of the resync does not have volume efficiency enabled or if reducing resync time is more important than preserving all possible storage efficiency. When this parameter is specified, resync does not preserve the storage efficiency of the new data with existing data over the wire and on the destination.

\[<true|false>|-is-auto-expand-enabled\] - Is Auto Expand Enabled

This optional parameter specifies whether or not a FlexGroup SnapMirror relationship and its destination FlexGroup should be auto-expanded if the source FlexGroup is expanded. This parameter is supported only for FlexGroup SnapMirror relationships. If this resync is creating a new Snapmirror relationship, the default value
is true. If it is not creating a new relationship, if a value is specified, it must match the current value for the existing relationship. If the parameter is not specified, the existing value will be retained.

[-foreground | -w [true]] - Foreground Process

This specifies whether the operation runs as a foreground process. If this parameter is specified, the default setting is true (the operation runs in the foreground). When set to true, the command will not return until the process completes. This parameter is only applicable to relationships with "Relationship Capability" of "Pre 8.2".

Examples

To reestablish mirroring for the destination endpoint vs2.example.com:dept_mkt_mirror that has been previously broken off with the snapmirror break command, type the following command:

```
vs2.example.com::> snapmirror resync -destination-path vs2.example.com:dept_mkt_dp_mirror
```

For relationships with "Relationship Capability" of "Pre 8.2", to reestablish mirroring for the destination endpoint cluster2://vs2.example.com/dept_mkt_mirror that has been previously broken off with the snapmirror break command, type the following command:

```
cluster2::> snapmirror resync -destination-path cluster2://vs2.example.com/dept_mkt_dp_mirror
```

To create a SnapMirror relationship and reestablish mirroring between the destination endpoint named vs2.example.com:dept_engine_dp_mirror2 and the source endpoint named vs1.example.com:dept_eng, type the following command:

```
vs2.example.com::> snapmirror resync -destination-path vs2.example.com:dept_engine_dp_mirror2 -source-path vs1.example.com:dept_eng
```

To create a SnapMirror relationship and reestablish mirroring between the destination endpoint named cluster2://vs2.example.com/dept_engine_dp_mirror2 and the source endpoint named cluster1://vs1.example.com/ dept_eng when the source cluster is running Data ONTAP 8.1 software, type the following command:

```
cluster2::> snapmirror resync -destination-path cluster2://vs2.example.com/dept_engine_dp_mirror2 -source-path cluster1://vs1.example.com/dept_eng
```

To create and reestablish an extended data protection (XDP) relationship between the Data ONTAP source endpoint vs1.example.com:data_ontap_vol, and the non-Data ONTAP (for example, AltaVault) destination endpoint 10.0.0.11:/share/share1, and start the initial transfer, type the following command:

```
vs1.example.com::> snapmirror resync -destination-path 10.0.0.11:/share/share1 -source-path vs1.example.com:data_ontap_vol -type XDP
```

To reestablish mirroring for the destination endpoint dvs1.example.com: of a Vserver relationship that has been previously broken off with the snapmirror break command, type the following command:

```
cluster2::> snapmirror resync -destination-path dvs1.example.com:
```

Under PVR control to create a SnapMirror synchronous Consistency Group relationship with the following attributes:

- It is between the source Consistency Group cg_src in Vserver vs1.example.com, and the destination Consistency Group cg_dst in Vserver vs2.example.com.
It has item mappings between lun1 and lun2 on volume srcvol and lun1 and lun2 on volume dstvol.

It uses a policy named Sync that has a policy type of smgr-mirror that the user has previously created.

and reestablish mirroring, type the following command:

```bash
vs2.example.com::> snapmirror resync -destination-path
vs2.example.com:/cg/cg_dst -source-path
vs1.example.com:/cg/cg_src -type XDP -policy Sync
-cg-item-mappings /vol/srcvol/lun1:@/vol/dstvol/lun1,
/vol/srcvol/lun2:@/vol/dstvol/lun2
```

Under PVR control to reestablish mirroring to the destination Consistency Group cg_dst in Vserver vs2.example.com that has been previously broken off with the snapmirror break command, type the following command:

```bash
vs2.example.com::> snapmirror resync -destination-path
vs2.example.com:/cg/cg_dst
```

**snapmirror set-options**

Display/Set SnapMirror options

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**
The snapmirror set-options command can be used to display or set snapmirror options.

**Parameters**

- `[-dp-source-xfer-reserve-pct (0|25%|50%|75%|100%)]` - Percentage Reserved for DP Source Transfers
  
  Specifies the percentage of maximum allowed concurrent transfers reserved for source DP transfers

- `[-xdp-source-xfer-reserve-pct (0|25%|50%|75%|100%)]` - Percentage Reserved for XDP Source Transfers
  
  Specifies the percentage of maximum allowed concurrent transfers reserved for source XDP transfers

- `[-dp-destination-xfer-reserve-pct (0|25%|50%|75%|100%)]` - Percentage Reserved for DP Destination Transfers
  
  Specifies the percentage of maximum allowed concurrent transfers reserved for destination DP transfers
[\texttt{-xdp-destination-xfer-reserve-pct \{0\%|25\%|50\%|75\%|100\%\}]} - Percentage Reserved for XDP Destination Transfers

Specifies the percentage of maximum allowed concurrent transfers reserved for destination XDP transfers.

**Examples**

The following example displays SnapMirror options:

```
cluster1::> snapmirror set-options
Percentage Reserved for DP Source Transfers: 0
Percentage Reserved for XDP Source Transfers: 0
Percentage Reserved for DP Destination Transfers: 0
Percentage Reserved for XDP Destination Transfers: 0
cluster1::> snapmirror set-options -dp-source-xfer-reserve-pct 25
    -xdp-source-xfer-reserve-pct 50
    -dp-destination-xfer-reserve-pct 0
    -xdp-destination-xfer-reserve-pct 50
cluster1::> snapmirror set-options
Percentage Reserved for DP Source Transfers: 25
Percentage Reserved for XDP Source Transfers: 50
Percentage Reserved for DP Destination Transfers: 0
Percentage Reserved for XDP Destination Transfers: 50
```

**snapmirror show**

Display a list of SnapMirror relationships.

**Availability:** This command is available to `cluster` and `Vserver` administrators at the `admin` privilege level.

**Description**

The `snapmirror show` command displays information associated with SnapMirror relationships. By default, the command displays the following information:

- Source path
- Relationship Type
- Destination Path
- Mirror State
- Relationship Status
- Total Progress
- Healthy
- Progress Last Updated

For backward compatibility with clustered Data ONTAP 8.1, and to accommodate load-sharing relationships which are only supported in a Data ONTAP 8.1 compatible way, SnapMirror relationships, which match one of the following conditions are managed as on clustered Data ONTAP 8.1: (1) The relationship is of type load-sharing; (2) The source endpoint of the relationship is on a remote Data ONTAP 8.1 cluster; (3) The local cluster was upgraded from clustered Data ONTAP 8.1, the relationship was created before the upgrade, and the relationship has not yet been converted to one with Data ONTAP 8.2 capabilities. These relationships have the same limitations as on clustered Data ONTAP 8.1. Especially, they support the same set of information fields. The "Relationship Capability" field is set to "Pre 8.2" for these relationships.

The `snapmirror show` command displays information for SnapMirror relationships whose destination endpoints are in the current Vserver if you are in a Vserver context, or in the current cluster if you are in a cluster context, or on a non-Data ONTAP endpoint that supports SnapMirror (for example, AltaVault). For backward compatibility with clustered Data ONTAP 8.1, the
command also displays information for SnapMirror relationships with the "Relationship Capability" of "Pre 8.2", and whose source endpoints are in the current Vserver or cluster, and destination endpoints are in different Vservers or clusters. You must use the `snapmirror list-destinations` command to display information for SnapMirror relationships whose source endpoints are in the current Vserver or current cluster.

Some of the SnapMirror relationship information is cached. The `snapmirror show` command only returns the cached information, therefore there is a delay after the information is changed before it is reflected in the `snapmirror show` output. Other information, such as progress metrics during a transfer, is only updated periodically and can be very delayed in the `snapmirror show` output.

The `-instance` and `-fields` parameters are mutually exclusive and select the information fields that are displayed. The other parameters to the `snapmirror show` command select the SnapMirror relationships for which information is displayed. The `-instance` displays detailed information fields including:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Source Path</td>
<td>Path of the source endpoint.</td>
</tr>
<tr>
<td>Destination Path</td>
<td>Path of the destination endpoint.</td>
</tr>
<tr>
<td>Relationship Type</td>
<td>Type of the SnapMirror relationship. Can be one of the following:</td>
</tr>
<tr>
<td></td>
<td>- DP: Data protection relationship.</td>
</tr>
<tr>
<td></td>
<td>- LS: Load-sharing relationship.</td>
</tr>
<tr>
<td></td>
<td>- XDP: Extended data protection relationship.</td>
</tr>
<tr>
<td></td>
<td>- RST: Temporary relationship created during a restore operation, and deleted if the operation completes successfully.</td>
</tr>
<tr>
<td></td>
<td>- TDP: 7-mode to clustered Data ONTAP transition data protection relationship.</td>
</tr>
</tbody>
</table>

Relationship Group Type: For FlexVol relationships, specifies the type of the group relationship that includes this FlexVol. For group relationships, specifies the type of the group relationship. Can be one of the following:
- none: No group relationship.
- vserver: Vserver relationship.
- flexgroup: FlexGroup relationship.

Relationship Status: Status of the SnapMirror relationship. Can be one of the following:
- Idle: No transfer operation is in progress and future transfers are not disabled.
- Queued: A transfer operation has been accepted and queued in the system, and future transfers are not disabled.
- Transferring: A transfer operation is in progress and future transfers are not disabled.
- Preparing: Pre-transfer phase for Vault incremental transfers.
- Finalizing: Post-transfer phase for Vault incremental transfers. Network traffic will be low as processing is primarily on the destination volume.
- Aborting: A transfer abort operation that might include the removal of
the checkpoint is underway. Future transfers are not disabled. Only for relationships with "Relationship Capability" of "8.2 and above".
- Quiesced: No transfer operation is in progress and future transfers are disabled.
- Quiescing: A transfer operation is in progress and future transfers are disabled.
- Checking: Destination volume is undergoing a diagnostic check, no transfer is in progress, and future transfers are not disabled. Only for relationships with "Relationship Capability" of "Pre 8.2".
- Breaking: The SnapMirror relationship is being broken off and no transfer is in progress.

The following values are only applicable to relationships with policy type sync-mirror or strict-sync-mirror:
- OutOfSync: The SnapMirror relationship is not InSync and no async transfer operation is in progress.
- Transitioning: The SnapMirror relationship is transitioning to InSync.
- InSync: The SnapMirror relationship is InSync.

Mirror State: State of the destination volume. Can be one of the following:
- Uninitialized: Destination volume has not been initialized.
- Snapmirrored: Destination volume has been initialized and is ready to receive SnapMirror updates.
- Broken-off: Destination volume is RW and snapshots are present.

Healthy: Condition of the relationship. Can be one of the following:
- true: The SnapMirror relationship is healthy. It has not missed a scheduled transfer, or experienced a manual update failure.
- false: The SnapMirror relationship is not healthy. It has missed a scheduled transfer, or has experienced a manual update failure.

Unhealthy Reason: Reason the SnapMirror relationship is not healthy. Only for relationships with "Relationship Capability" of "8.2 and above"

Newest Snapshot: Name of the newest Snapshot copy on the destination volume.
Newest Snapshot Timestamp: Timestamp of the newest Snapshot copy.
Exported Snapshot: Name of the exported Snapshot copy on the destination volume.
Exported Snapshot Timestamp: Timestamp of the exported Snapshot copy.
Lag Time: Time since the exported Snapshot copy was created. It is displayed in the format: hours:minutes:seconds.
Only for relationships with
"Relationship Capability" of "8.2 and above".

**Transfer Type:** Type of the current transfer operation. Can be one of the following:
- initialize
- update
- resync
- restore

Only for relationships with "Relationship Capability" of "8.2 and above".

**Transfer Snapshot:** Name of the Snapshot copy being transferred.

**Snapshot Progress:** Amount of data transferred for the transfer snapshot. This parameter is not supported for SnapMirror FlexGroup relationships, but it is supported for FlexGroup constituent relationships.

**Total Progress:** Total amount of data transferred for the current transfer operation. This parameter is not supported for SnapMirror FlexGroup relationships, but it is supported for FlexGroup constituent relationships.

**Network Compression Ratio:** The compression ratio achieved for the data sent over the wire as a part of the current transfer operation. The ratio is not maintained across checkpoint restarts. If network compression is disabled for the transfer, the ratio will be set to 1:1.

Only for relationships with "Relationship Capability" of "8.2 and above".

This parameter is not supported for Vserver or FlexGroup SnapMirror relationships, but it is supported for FlexGroup constituent relationships.

**Snapshot Checkpoint:** The amount of data transferred as recorded in the restart checkpoint of the current or most recent transfer snapshot. If a restart checkpoint is present the next transfer will continue from the checkpoint. This parameter is not supported for SnapMirror FlexGroup relationships, but it is supported for FlexGroup constituent relationships.

**Transfer Error:** Possible transient error condition if any, encountered by the current transfer operation.

Only for relationships with "Relationship Capability" of "8.2 and above".

**Current Throttle:** The maximum transfer rate in Kilobytes per second, used for the current transfer between clusters.

Only for relationships with "Relationship Capability" of "8.2 and above".

**Current Transfer Priority:** Priority assigned to the current transfer. Possible values are:
- low
- normal

Only for relationships with "Relationship Capability" of "8.2 and above".

**Last Transfer Type:** Type of the previous transfer operation:
- initialize
- update
- resync
- restore

Only for relationships with "Relationship Capability" of "8.2 and above".
Last Transfer Size: Total amount of data transferred during the previous transfer operation if it was successful. Only for relationships with "Relationship Capability" of "8.2 and above". This parameter is not supported for SnapMirror FlexGroup relationships, but it is supported for FlexGroup constituent relationships.

Last Transfer Network Compression Ratio: The compression ratio achieved for the data sent over the wire as a part of the previous transfer operation. If network compression was disabled for the transfer, the ratio will be set to 1:1. Only for relationships with "Relationship Capability" of "8.2 and above". This parameter is not supported for Vserver or FlexGroup SnapMirror relationships, but it is supported for FlexGroup constituent relationships.

Last Transfer Duration: Duration of the previous transfer operation if it was successful. Only for relationships with "Relationship Capability" of "8.2 and above".

Last Transfer From: Source endpoint of the previous transfer operation. Only for relationships with "Relationship Capability" of "8.2 and above".

Last Transfer End Timestamp: Timestamp of the end of the previous transfer operation. Only for relationships with "Relationship Capability" of "8.2 and above".

Last Transfer Error: Cause of the failure of the previous transfer operation. Only for relationships with "Relationship Capability" of "8.2 and above".

Relationship Capability: Management and control compatibility:
- "Pre 8.2": Management and control of the relationship is compatible with clustered Data ONTAP 8.1.
- "8.2 and above": Full support of clustered Data ONTAP 8.2 or later SnapMirror relationship management and control. This parameter is not supported for Vserver SnapMirror relationships.

Relationship ID: The unique identifier of the relationship. Only for relationships with "Relationship Capability" of "8.2 and above". This parameter is not supported for Vserver SnapMirror relationships.

Current Operation ID: Operation unique identifier of the currently executing SnapMirror operation. Only for relationships with "Relationship Capability" of "8.2 and above".

Throttle (KB/sec): Configured maximum transfer rate for cross-cluster transfers.

SnapMirror Policy Type: Type of the SnapMirror policy associated with the relationship. Can be one of the following:
- async-mirror
- vault
- mirror-vault
Refer to the man page for the `snapmirror policy create` command for a description of what these types mean.

Only for relationships with "Relationship Capability" of "8.2 and above".

<table>
<thead>
<tr>
<th><strong>SnapMirror Policy</strong></th>
<th>Name of the SnapMirror policy associated with the relationship. Only for relationships with &quot;Relationship Capability&quot; of &quot;8.2 and above&quot;.</th>

Commands: Manual Page Reference
Only for relationships with "Relationship Capability" of "8.2 and above". This parameter is not supported for Vserver SnapMirror relationships.

Number of Failed Updates: The number of failed SnapMirror update operations for the relationship. Only for relationships with "Relationship Capability" of "8.2 and above". This parameter is not supported for Vserver SnapMirror relationships.

Number of Successful Resyncs: The number of successful SnapMirror resync operations for the relationship. Only for relationships with "Relationship Capability" of "8.2 and above". This parameter is not supported for Vserver SnapMirror relationships.

Number of Failed Resyncs: The number of failed SnapMirror resync operations for the relationship. Only for relationships with "Relationship Capability" of "8.2 and above". This parameter is not supported for Vserver SnapMirror relationships.

Number of Successful Breaks: The number of successful SnapMirror break operations for the relationship. Only for relationships with "Relationship Capability" of "8.2 and above". This parameter is not supported for Vserver SnapMirror relationships.

Number of Failed Breaks: The number of failed SnapMirror break operations for the relationship. Only for relationships with "Relationship Capability" of "8.2 and above". This parameter is not supported for Vserver SnapMirror relationships.

Total Transfer Bytes: Cumulative bytes transferred for the relationship. Only for relationships with "Relationship Capability" of "8.2 and above". This parameter is not supported for Vserver or FlexGroup SnapMirror relationships, but it is supported for FlexGroup constituent relationships.

Total Transfer Time: Cumulative total transfer time in seconds for the relationship. Only for relationships with "Relationship Capability" of "8.2 and above". This parameter is not supported for Vserver SnapMirror relationships.

Parameters

[-fields <fieldname>, ...]

If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

[-instance]

If you specify the -instance parameter, the command displays detailed information about all fields.

snapmirror show
Select SnapMirror relationships that have a matching source path name.

Select SnapMirror relationships that have a matching source cluster name. This parameter is not supported for relationships with non-Data ONTAP source endpoints.

Select SnapMirror relationships that have a matching source Vserver name. This parameter is not supported for relationships with non-Data ONTAP source endpoints.

Select SnapMirror relationships that have a matching source volume name. This parameter is not supported for relationships with non-Data ONTAP source endpoints.

Select SnapMirror relationships that have a matching destination path name.

Note: Using wildcards with this parameter:

- To match all Vserver Snapmirror relationships, use: \(-destination-path *\):
- To match all the Snapmirror relationships except Vserver Snapmirror relationships in the cluster, use: \(-destination-path *\)

Select SnapMirror relationships that have a matching destination cluster name. This parameter is not supported for relationships with non-Data ONTAP destination endpoints.

Select SnapMirror relationships that have a matching destination Vserver name. This parameter is not supported for relationships with non-Data ONTAP destination endpoints.

Select SnapMirror relationships that have a matching destination volume name. This parameter is not supported for relationships with non-Data ONTAP destination endpoints.

Select SnapMirror relationships that have a matching relationship type. Vservers support only DP SnapMirror relationships. Possible values are:

- DP
- LS
- XDP
- TDP
- RST

Select SnapMirror relationships that have a matching relationship group type. Possible values are:

- none
- vserver
• flexgroup

[\texttt{-vserver <vserver name>}] - Managing Vserver

Select SnapMirror relationships that have a matching managing Vserver name. The \texttt{-vserver} option is currently a reserved option.

[\texttt{-schedule <text>}] - SnapMirror Schedule

Select SnapMirror relationships that have a matching schedule.

[\texttt{-policy-type \{vault|async-mirror|mirror-vault|strict-sync-mirror|sync-mirror\}}] - SnapMirror Policy Type

Selects SnapMirror relationships that have a matching SnapMirror policy type. Possible values are:

• async-mirror
• vault
• mirror-vault

[\texttt{-policy <sm_policy>}] - SnapMirror Policy

Select SnapMirror relationships that have a matching SnapMirror policy.

[\texttt{-tries <unsigned32_or_unlimited>}] - Tries Limit

Select SnapMirror relationships that have a matching tries limit.

[\texttt{-throttle|-k <throttleType>}] - Throttle (KB/sec)

Select SnapMirror relationships that have a matching throttle.

[\texttt{-current-throttle <throttleType>}] - Current Transfer Throttle (KB/sec)

Select SnapMirror relationships that have a current transfer throttle.

[\texttt{-state <mirror state>}] - Mirror State

Select SnapMirror relationships that have a matching mirror state. Possible values are:

• Uninitialized
• Snapmirrored
• Broken-off

[\texttt{-status <mirror status>}] - Relationship Status

Select SnapMirror relationships that have a matching relationship status. Possible values are:

• Idle
• Queued
• Transferring
• Preparing
• Finalizing
• Aborting
• Quiesced
• Quiescing
• Checking

Status values Finalizing, Checking, Waiting and Preparing are not supported for Vserver SnapMirror relationships.
### File Restore File Count
The number of files being restored by file restore.

### File Restore File List
List of the destination file names of the files being restored by file restore.

### Transfer Snapshot
Select SnapMirror relationships that have a matching transfer Snapshot copy.

### Snapshot Progress
Select SnapMirror relationships that have a matching Snapshot progress.

### Total Progress
Select SnapMirror relationships that have a matching total progress.

### Network Compression Ratio
Select SnapMirror relationships that have a matching network compression ratio. This parameter is not supported for Vserver SnapMirror relationships.

### Snapshot Checkpoint
Select SnapMirror relationships that have a matching Snapshot copy checkpoint. This parameter is not supported for Vserver SnapMirror relationships.

### Newest Snapshot
Select SnapMirror relationships that have a matching newest Snapshot copy.

### Newest Snapshot Timestamp
Select SnapMirror relationships that have a matching newest Snapshot copy timestamp.

### Exported Snapshot
Select SnapMirror relationships that have a matching exported Snapshot copy name. For load-sharing mirror relationships, if the exported-snapshot field for a relationship has a dash (-), the load-sharing mirror is lagging behind the up-to-date mirrors in the set.

### Exported Snapshot Timestamp
Select SnapMirror relationships that have a matching exported Snapshot copy timestamp.

### Healthy
Select SnapMirror relationships that have a matching healthy condition.

### Relationship ID
Select SnapMirror relationships that have a matching relationship ID. This parameter is not supported for Vserver SnapMirror relationships.

### Current Operation ID
Select SnapMirror relationships that have a matching operation unique identifier of the currently executing SnapMirror operation.

### Transfer Type
Select SnapMirror relationships that have a matching current transfer type.

### Transfer Error
Select SnapMirror relationships that have a matching current transfer error.

### Last Transfer Type
Select SnapMirror relationships that have a matching last transfer type.
[-last-transfer-error <text>] - Last Transfer Error
Select SnapMirror relationships that have a matching last transfer error.

[-last-transfer-size <integer>{KB|MB|GB|TB|PB}] - Last Transfer Size
Select SnapMirror relationships that have a matching last transfer size.

[-last-transfer-network-compression-ratio <text>] - Last Transfer Network Compression Ratio
Select SnapMirror relationships that have a matching last transfer network compression ratio. This parameter is not supported for Vserver SnapMirror relationships.

[-last-transfer-duration <[<hours>:]<minutes>:]<seconds>] - Last Transfer Duration
Select SnapMirror relationships that have a matching last transfer duration.

[-last-transfer-from <text>] - Last Transfer From
Select SnapMirror relationships that have a matching last transfer source.

[-last-transfer-end-timestamp <MM/DD HH:MM:SS>] - Last Transfer End Timestamp
Select SnapMirror relationships that have a matching last transfer end timestamp.

[-unhealthy-reason <text>] - Unhealthy Reason
Select SnapMirror relationships that have a matching unhealthy reason.

[-progress-last-updated <MM/DD HH:MM:SS>] - Progress Last Updated
Select SnapMirror relationships that have a matching progress last updated.

[-relationship-capability <text>] - Relationship Capability
Select SnapMirror relationships that have a matching relationship capability. This parameter is not supported for Vserver SnapMirror relationships.

[-lag-time <[<hours>:]<minutes>:]<seconds>] - Lag Time
Select SnapMirror relationships that have a matching lag time.

[-current-transfer-priority {low|normal}] - Current Transfer Priority
Select SnapMirror relationships that have a matching current transfer priority.

[-is-smtape-op {true|false}] - SMTape Operation
Select SnapMirror relationships that have a matching smtape operation.

[-destination-volume-node <nodename>] - Destination Volume Node Name
Select SnapMirror relationships that have a matching destination volume node name. This parameter is not supported for Vserver SnapMirror relationships.

[-identity-preserve {true|false}] - Identity Preserve Vserver DR
Select SnapMirror relationships that have a matching value for identity-preserve. This parameter is valid only for Vserver SnapMirror relationships.

[-expand {true}] - Show Constituents of the Group
Specifies whether to display constituent relationships of Vserver and FlexGroup SnapMirror relationships. By default, the constituents are not displayed.

[-update-successful-count <integer>] - Number of Successful Updates
Select SnapMirror relationships that have a matching number of successful updates. This parameter is not supported for Vserver SnapMirror relationships.

[-update-failed-count <integer>] - Number of Failed Updates
Select SnapMirror relationships that have a matching number of failed updates. This parameter is not supported for Vserver SnapMirror relationships.
[-resync-successful-count <integer>] - Number of Successful Resyncs
Select SnapMirror relationships that have a matching number of successful resyncs. This parameter is not supported for Vserver SnapMirror relationships.

[-resync-failed-count <integer>] - Number of Failed Resyncs
Select SnapMirror relationships that have a matching number of failed resyncs. This parameter is not supported for Vserver SnapMirror relationships.

[-break-successful-count <integer>] - Number of Successful Breaks
Select SnapMirror relationships that have a matching number of successful breaks. This parameter is not supported for Vserver SnapMirror relationships.

[-break-failed-count <integer>] - Number of Failed Breaks
Select SnapMirror relationships that have a matching number of failed breaks. This parameter is not supported for Vserver SnapMirror relationships.

[-total-transfer-bytes <integer>] - Total Transfer Bytes
Select SnapMirror relationships that have a matching total transfer bytes. This parameter is not supported for Vserver SnapMirror relationships.

[-total-transfer-time-secs <integer>] - Total Transfer Time in Seconds
Select SnapMirror relationships that have a matching total transfer time in seconds. This parameter is not supported for Vserver SnapMirror relationships.

[-msid-preserve {true|false}] - Source Volume MSIDs Preserved
This parameter specifies whether the volume MSIDs are preserved at the destination. This parameter is applicable only for Vserver SnapMirror relationships.

[-is-auto-expand-enabled {true|false}] - Is Auto Expand Enabled
Select SnapMirror relationships that have a matching value for auto expand. This parameter is supported only for FlexGroup SnapMirror relationships. Possible values are:

• true
• false

Examples
The snapmirror show command displays information associated with SnapMirror relationships. By default, the command displays the following information:

• Source path
• Relationship Type
• Destination Path
• Mirror State
• Relationship Status
• Total Progress
• Healthy
• Progress Last Updated

For backward compatibility with clustered Data ONTAP 8.1, and to accommodate load-sharing relationships which are only supported in a Data ONTAP 8.1 compatible way, SnapMirror relationships, which match one of the following conditions are managed as on clustered Data ONTAP 8.1: (1) The relationship is of type load-sharing; (2) The source endpoint of the relationship is on a remote Data ONTAP 8.1 cluster; (3) The local cluster was upgraded from clustered Data ONTAP 8.1, the relationship was created before the upgrade, and the relationship has not yet been converted to one
with Data ONTAP 8.2 capabilities. These relationships have the same limitations as on clustered Data ONTAP 8.1. Especially, they support the same set of information fields. The "Relationship Capability" field is set to "Pre 8.2" for these relationships.

The `snapmirror show` command displays information for SnapMirror relationships whose destination endpoints are in the current Vserver if you are in a Vserver context, or in the current cluster if you are in a cluster context, or on a non-Data ONTAP endpoint that supports SnapMirror (for example, AltaVault). For backward compatibility with clustered Data ONTAP 8.1, the command also displays information for SnapMirror relationships with the "Relationship Capability" of "Pre 8.2", and whose source endpoints are in the current Vserver or cluster, and destination endpoints are in different Vservers or clusters. You must use the `snapmirror list-destinations` command to display information for SnapMirror relationships whose source endpoints are in the current Vserver or current cluster.

Some of the SnapMirror relationship information is cached. The `snapmirror show` command only returns the cached information, therefore there is a delay after the information is changed before it is reflected in the `snapmirror show` output. Other information, such as progress metrics during a transfer, is only updated periodically and can be very delayed in the `snapmirror show` output.

The `-instance` and `-fields` parameters are mutually exclusive and select the information fields that are displayed. The other parameters to the `snapmirror show` command select the SnapMirror relationships for which information is displayed. The `-instance` displays detailed information fields including:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Source Path</td>
<td>Path of the source endpoint.</td>
</tr>
<tr>
<td>Destination Path</td>
<td>Path of the destination endpoint.</td>
</tr>
<tr>
<td>Relationship Type</td>
<td>Type of the SnapMirror relationship. Can be one of the following:</td>
</tr>
<tr>
<td></td>
<td>- DP: Data protection relationship.</td>
</tr>
<tr>
<td></td>
<td>- LS: Load-sharing relationship.</td>
</tr>
<tr>
<td></td>
<td>- XDP: Extended data protection relationship.</td>
</tr>
<tr>

<tr>
<td>Under PVR control</td>
<td>The following group type is available:</td>
</tr>
<tr>
<td></td>
<td>- consistencygroup: Consistency Group relationship.</td>
</tr>
<tr>
<td></td>
<td>There are no FlexVol relationships with group type of consistencygroup, only Consistency Group relationships and item-level relationships.</td>
</tr>
<tr>
<td>Only for relationships with &quot;Relationship Capability&quot; of &quot;8.2 and above&quot;</td>
<td>Relationship Status: Status of the SnapMirror relationship. Can be one of the following:</td>
</tr>
<tr>
<td></td>
<td>- Idle: No transfer operation is in progress and future transfers are not disabled.</td>
</tr>
<tr>
<td></td>
<td>- Queued: A transfer operation has been accepted and queued in the system, and future transfers are not disabled.</td>
</tr>
</tbody>
</table>
- Transferring: A transfer operation is in progress and future transfers are not disabled.
- Preparing: Pre-transfer phase for Vault incremental transfers.
  For Vault relationships only.
- Finalizing: Post-transfer phase for Vault incremental transfers. Network traffic will be low as processing is primarily on the destination volume.
  For Vault relationships only.
- Aborting: A transfer abort operation that might include the removal of the checkpoint is underway. Future transfers are not disabled. Only for relationships with "Relationship Capability" of "8.2 and above".
- Quiesced: No transfer operation is in progress and future transfers are disabled.
- Quiescing: A transfer operation is in progress and future transfers are disabled.
- Checking: Destination volume is undergoing a diagnostic check, no transfer is in progress, and future transfers are not disabled. Only for relationships with "Relationship Capability" of "Pre 8.2".
- Breaking: The SnapMirror relationship is being broken off and no transfer is in progress.

The following values are only applicable to relationships with policy type sync-mirror or strict-sync-mirror:
- OutOfSync: The SnapMirror relationship is not InSync and no async transfer operation is in progress.
- Transitioning: The SnapMirror relationship is transitioning to InSync.
- InSync: The SnapMirror relationship is InSync.

The following values are only applicable to relationships with policy type smgr-mirror under PVR control:
- PreCutover: The SnapMirror relationship is setting up for the last transfer prior Cutover to InSync.
- Cutover: The SnapMirror relationship is transitioning to InSync.

Mirror State: State of the destination volume. Can be one of the following:
- Uninitialized: Destination volume has not been initialized.
- Snapmirrored: Destination volume has been initialized and is ready to receive SnapMirror updates.
- Broken-off: Destination volume is RW and snapshots are present.

Healthy: Condition of the relationship. Can be one of the following:
- true: The SnapMirror relationship is healthy. It has not missed a scheduled transfer, or experienced a manual update failure.
- **false**: The SnapMirror relationship is not healthy. It has missed a scheduled transfer, or has experienced a manual update failure.

**Unhealthy Reason**: Reason the SnapMirror relationship is not healthy. Only for relationships with "Relationship Capability" of "8.2 and above"

**Newest Snapshot**: Name of the newest Snapshot copy on the destination volume.

**Newest Snapshot Timestamp**: Timestamp of the newest Snapshot copy.

**Exported Snapshot**: Name of the exported Snapshot copy on the destination volume.

**Exported Snapshot Timestamp**: Timestamp of the exported Snapshot copy.

**Lag Time**: Time since the exported Snapshot copy was created. It is displayed in the format: hours:minutes:seconds. Only for relationships with "Relationship Capability" of "8.2 and above".

**Transfer Type**: Type of the current transfer operation. Can be one of the following:
- initialize
- update
- resync
- restore

Only for relationships with "Relationship Capability" of "8.2 and above".

**Transfer Snapshot**: Name of the Snapshot copy being transferred.

**Snapshot Progress**: Amount of data transferred for the transfer snapshot. This parameter is not supported for SnapMirror FlexGroup relationships, but it is supported for FlexGroup constituent relationships.

**Total Progress**: Total amount of data transferred for the current transfer operation. This parameter is not supported for SnapMirror FlexGroup relationships, but it is supported for FlexGroup constituent relationships.

**Network Compression Ratio**: The compression ratio achieved for the data sent over the wire as a part of the current transfer operation. The ratio is not maintained across checkpoint restarts. If network compression is disabled for the transfer, the ratio will be set to 1:1. Only for relationships with "Relationship Capability" of "8.2 and above". This parameter is not supported for Vserver or FlexGroup SnapMirror relationships, but it is supported for FlexGroup constituent relationships.

**Snapshot Checkpoint**: The amount of data transferred as recorded in the restart checkpoint of the current or most recent transfer snapshot. If a restart checkpoint is present the next transfer will continue from the checkpoint. This parameter is not supported for SnapMirror FlexGroup relationships, but it is supported for FlexGroup constituent relationships.

**Transfer Error**: Possible transient error condition if any, encountered by the current transfer operation. Only for relationships with "Relationship Capability" of "8.2 and above".

**Current Throttle**: The maximum transfer rate in Kilobytes per second, used for the current transfer between clusters. Only for relationships with "Relationship Capability" of "8.2 and above".

**Current Transfer Priority**: Priority assigned to the current transfer. Possible values are:
- low
- normal

Only for relationships with "Relationship Capability" of "8.2 and above".
"Relationship Capability" of "8.2 and above".

Last Transfer Type: Type of the previous transfer operation:
- initialize
- update
- resync
- restore
Only for relationships with "Relationship Capability" of "8.2 and above".

Last Transfer Size: Total amount of data transferred during the previous transfer operation if it was successful.
Only for relationships with "Relationship Capability" of "8.2 and above".
This parameter is not supported for SnapMirror FlexGroup relationships, but it is supported for FlexGroup constituent relationships.

Last Transfer Network Compression Ratio: The compression ratio achieved for the data sent over the wire as a part of the previous transfer operation. If network compression was disabled for the transfer, the ratio will be set to 1:1.
Only for relationships with "Relationship Capability" of "8.2 and above".
This parameter is not supported for Vserver or FlexGroup SnapMirror relationships, but it is supported for FlexGroup constituent relationships.

Last Transfer Duration: Duration of the previous transfer operation if it was successful.
Only for relationships with "Relationship Capability" of "8.2 and above".

Last Transfer From: Source endpoint of the previous transfer operation.
Only for relationships with "Relationship Capability" of "8.2 and above".

Last Transfer End Timestamp: Timestamp of the end of the previous transfer operation.
Only for relationships with "Relationship Capability" of "8.2 and above".

Last Transfer Error: Cause of the failure of the previous transfer operation.
Only for relationships with "Relationship Capability" of "8.2 and above".

Relationship Capability: Management and control compatibility:
- "Pre 8.2": Management and control of the relationship is compatible with clustered Data ONTAP 8.1.
- "8.2 and above": Full support of clustered Data ONTAP 8.2 or later SnapMirror relationship management and control.
This parameter is not supported for Vserver SnapMirror relationships.

Relationship ID: The unique identifier of the relationship.
Only for relationships with "Relationship Capability" of "8.2 and above".
This parameter is not supported for Vserver SnapMirror relationships.

Current Operation ID: Operation unique identifier of the currently executing SnapMirror operation.
Only for relationships with "Relationship Capability" of "8.2 and above".

Throttle (KB/sec): Configured maximum transfer rate for cross-cluster transfers.

SnapMirror Policy Type: Type of the SnapMirror policy associated with the relationship. Can be one of the
- async-mirror
- vault
- mirror-vault

Under PVR control the following type is available:
- sync-mirror

Refer to the man page for the `snapmirror policy create` command for a description of what these types mean. Only for relationships with "Relationship Capability" of "8.2 and above".

SnapMirror Policy: Name of the SnapMirror policy associated with the relationship. Only for relationships with "Relationship Capability" of "8.2 and above".

SnapMirror Schedule: Name of the schedule (empty if there is no schedule) associated with the relationship.

Tries Limit: Maximum number of times a transfer will be tried. Only for relationships with "Relationship Capability" of "Pre 8.2". This parameter is not supported for Vserver SnapMirror relationships.

Destination Volume Node: Node which owns the destination volume of the relationship. For FlexGroup relationships it is the node which owns the root constituent destination volume. Only for relationships with "Relationship Capability" of "8.2 and above". This parameter is not supported for Vserver SnapMirror relationships.

Identity Preserve Vserver DR: Whether or not the identity of the source Vserver is replicated to the destination Vserver. Can be:
- true: Source Vserver's configuration will additionally be replicated to the destination, along with the Vserver's volumes and RBAC configuration.
- false: Only volumes and RBAC configuration of the source Vserver is replicated to the destination. This parameter is supported only for Vserver SnapMirror relationships.

Volume MSIDs Preserved: Whether or not the MSIDs of the source volumes are retained while creating destination volumes. Can be:
- true: MSIDs of source Vserver volumes and destination Vserver volumes match.
- false: MSIDs of source Vserver volumes and destination Vserver volumes do not match. This parameter is supported only for Vserver SnapMirror relationships.

Is Auto Expand Enabled: Whether or not the auto expand is enabled. Can be:
- true: Auto Expand is enabled.
- false: Auto Expand is disabled. This parameter is supported only for FlexGroup SnapMirror relationships.

Is Adaptive Enabled: Whether or not adaptive is enabled. Can be:
- true: Adaptive is enabled.
- false: Adaptive is disabled.
This parameter is supported only for FlexVol SnapMirror relationships between Data ONTAP endpoints.

Number of Successful Updates: The number of successful SnapMirror update operations for the relationship.

- Only for relationships with "Relationship Capability" of "8.2 and above".
- This parameter is not supported for Vserver SnapMirror relationships.

Number of Failed Updates: The number of failed SnapMirror update operations for the relationship.

- Only for relationships with "Relationship Capability" of "8.2 and above".
- This parameter is not supported for Vserver SnapMirror relationships.

Number of Successful Resyncs: The number of successful SnapMirror resync operations for the relationship.

- Only for relationships with "Relationship Capability" of "8.2 and above".
- This parameter is not supported for Vserver SnapMirror relationships.

Number of Failed Resyncs: The number of failed SnapMirror resync operations for the relationship.

- Only for relationships with "Relationship Capability" of "8.2 and above".
- This parameter is not supported for Vserver SnapMirror relationships.

Number of Successful Breaks: The number of successful SnapMirror break operations for the relationship.

- Only for relationships with "Relationship Capability" of "8.2 and above".
- This parameter is not supported for Vserver SnapMirror relationships.

Number of Failed Breaks: The number of failed SnapMirror break operations for the relationship.

- Only for relationships with "Relationship Capability" of "8.2 and above".
- This parameter is not supported for Vserver SnapMirror relationships.

Total Transfer Bytes: Cumulative bytes transferred for the relationship.

- Only for relationships with "Relationship Capability" of "8.2 and above".
- This parameter is not supported for Vserver or FlexGroup SnapMirror relationships, but it is supported for FlexGroup constituent relationships.

Total Transfer Time: Cumulative total transfer time in seconds for the relationship.

- Only for relationships with "Relationship Capability" of "8.2 and above".
- This parameter is not supported for Vserver SnapMirror relationships.

The following fields are available only under PVR control for relationships with policy type `sync-mirror`.

Number of Successful PCS: The number of successful Pseudo Common Snapshot copy creation operations for the relationship. Pseudo Common Snapshot copies are created periodically for use by SnapMirror so that there is always a comparatively recent common Snapshot copy that can be used to get a relationship with policy type `sync-mirror` back InSync quickly.
Number of Failed PCS: The number of failed Pseudo Common Snapshot copy creation operations for the relationship.

Average Time of Resync Operations: Average duration in seconds of resync operations on relationships with policy type `sync-mirror`.

The following fields are available only at the diagnostic privilege level:

- **Last Transfer Error Codes**: Set of Data ONTAP internal error codes providing information on the context of the previous transfer failure. Only for relationships with "Relationship Capability" of "8.2 and above". This parameter is not supported for Vserver SnapMirror relationships.
- **Source Vserver UUID**: The unique identifier of the source Vserver. Only for relationships with "Relationship Capability" of "8.2 and above".
- **Destination Vserver UUID**: The unique identifier of the destination Vserver. Only for relationships with "Relationship Capability" of "8.2 and above".
- **Source Endpoint UUID**: The unique identifier of the non-Data ONTAP source endpoint of a relationship. Only for relationships with a non-Data ONTAP source endpoint.
- **Destination Endpoint UUID**: The unique identifier of the non-Data ONTAP destination endpoint of a relationship. Only for relationships with a non-Data ONTAP destination endpoint.

The example below displays summary information for all SnapMirror relationships with destination endpoints in the current cluster:

```
cluster2::> snapmirror show

The example shows the usage of the `--expand` parameter to additionally display the constituents of Vserver SnapMirror relationships with destination endpoints in the current cluster. Note that in the following example, since there is no volume level relationship for the root volume of a Vserver, it is not shown in the output:

```
ccluster2::> snapmirror show --expand
```

```
  Progress
  Source     Destination     Mirror  Relationship  Total             Last
  Path       Type   Path     State   Status       Progress  Healthy Updated
```

The example shows the usage of the `--expand` parameter to additionally display the constituents of Vserver SnapMirror relationships with destination endpoints in the current cluster. Note that in the following example, since there is no volume level relationship for the root volume of a Vserver, it is not shown in the output:

**snapmirror show-history**

Displays history of SnapMirror operations.

**Availability**: This command is available to cluster and Vserver administrators at the *admin* privilege level.

**Description**

The `snapmirror show-history` command displays the history of SnapMirror operations. This command is not supported for relationships with non-Data ONTAP endpoints.

By default, the command displays the following information:

- Destination Path
- Source Path
- Operation
- Start Time
- End Time
- Result

The `snapmirror show-history` command displays - in reverse chronological order - the history of completed SnapMirror operations whose destination endpoints are in the current Vserver for Vserver administrators, or the current cluster for cluster administrators. This command does not return information on the following operations and relationships:

- Operations that happened prior to installing Data ONTAP 8.3.
- Relationships with the "Relationship Capability" field, as shown in the output of the SnapMirror show command, set to "Pre 8.2".
- Operations on FlexGroup relationships that happened prior to installing Data ONTAP 9.5.
- Operations on FlexGroup constituent relationships.

The `-instance` parameter displays the following detailed information:
### Destination Path
Path of the destination endpoint.

### Source Path
Path of the source endpoint.

### Relationship ID
The unique identifier of the relationship. This parameter is not supported for Vserver SnapMirror relationships.

### Relationship Group Type
For FlexVol relationships, specifies the type of the group relationship that includes this FlexVol. For group relationships, specifies the type of the group relationship. Can be one of the following:
- none: No group relationship.
- vserver: Vserver relationship.
- flexgroup: FlexGroup relationship.

### Operation
Type of the operation. Can be one of the following:
- create
- modify
- quiesce
- resume
- delete
- initialize
- manual update
- scheduled update
- break
- resync
- abort
- restore

### Operation ID
The unique identifier of the operation.

### Start Time
Timestamp of the start of the operation.

### End Time
Timestamp of the end of the operation.

### Result
Result of the SnapMirror operation. Can be one of the following:
- success
- failure

### Transfer Size
Total amount of data transferred during the SnapMirror operation.

### Additional Information
A message describing the cause of the failure or additional information about a successful operation, such as if a checkpoint was cleared as part of an abort operation.

### Parameters

```
[-fields <fieldname>, ...]
```

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

```
[-instance]
```

If you specify the `-instance` parameter, the command displays detailed information about all fields.

```
[-destination-path (\<[vserver:]\>/\<volume\>|\<[cluster:]//\<vserver\>/\<volume\>|\<hostip:/lun/\<name\>|\<hostip:/share/\<share-name\>\)]) - Destination Path
```

Select SnapMirror operations that have a matching destination path name.

```
[-destination-vserver <vserver name>] - Destination Vserver
```

Select SnapMirror operations that have a matching destination Vserver name.

```
[-destination-volume <volume name>] - Destination Volume
```

Select SnapMirror operations that have a matching destination volume name.

```
[-operation-id <UUID>] - Operation ID
```

Select SnapMirror operations that have a matching operation ID.
Select SnapMirror operations that have a matching source path name.

Select SnapMirror operations that have a matching source Vserver name.

Select SnapMirror operations that have a matching source volume name.

Select SnapMirror operations that have a matching operation type. Possible values are:

- create
- modify
- quiesce
- resume
- delete
- initialize
- manual-update
- scheduled-update
- break
- resync
- abort
- restore

Select SnapMirror operations that have a matching start time.

**snapmirror update**

Start an incremental transfer

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

**Description**

The `snapmirror update` command updates the destination volume or non-Data ONTAP endpoint of a SnapMirror relationship. The `snapmirror update` command behaves differently for data protection (DP), extended data protection (XDP)
and load-sharing (LS) relationships. Refer to the `-type` parameter of the `snapmirror create` command to understand different types of relationships supported by SnapMirror.

The `snapmirror update` command performs an incremental transfer.

Before using this command, the relationship must be initialized using the `snapmirror initialize` or `snapmirror initialize-ls-set` commands.

For data protection SnapMirror relationships with volumes as endpoints, the `snapmirror update` command makes the destination volume an up-to-date mirror of the source volume with the following steps:

- If the source volume is read-write, takes a Snapshot copy on the source volume to capture the current image of the source volume
- Finds the most recent Snapshot copy on the destination volume and validates that the corresponding Snapshot copy is still present on the source
- Incrementally transfers Snapshot copies that are newer than the corresponding Snapshot copy to the destination volume

You can use the `snapmirror update` command to update a specific load-sharing mirror that lags behind up-to-date destination volumes in the set of load-sharing mirrors. An update to the lagging load-sharing mirror should bring it up to date with the other up-to-date destination volumes in the set of load-sharing mirrors.

**Note:** Using the `snapmirror update` command to update a set of load-sharing mirrors will not work. Use the `snapmirror update-ls-set` command to update a set of load-sharing mirrors.

For extended data protection (XDP) relationships with a `snapmirror policy` of type `async-mirror`, a `snapmirror update` always creates a new Snapshot copy on the source volume. Depending on the rules in the policy, the command might transfer just the newly created Snapshot copy or all Snapshot copies that are newer than the common Snapshot copy including the newly created Snapshot copy to the destination volume.

For extended data protection (XDP) relationships with a `snapmirror policy` of type `vault`, a `snapmirror update` does not create a new Snapshot copy on the source volume but transfers only selected Snapshot copies that are newer than the common Snapshot copy to the destination volume. (Those older than the common copy can be transferred by using the `-source-snapshot` parameter.) Snapshot copies are selected by matching the value of `-snapmirror-label` of a Snapshot copy with the value of `-snapmirror-label` of one of the rules from the corresponding SnapMirror policy associated with the SnapMirror relationship. All matching Snapshot copies are incrementally transferred to the destination volume.

For extended data protection (XDP) relationships with a `snapmirror policy` of type `mirror-vault`, a `snapmirror update` always creates a new Snapshot copy on the source volume and transfers only selected Snapshot copies that are newer than the common snapshot copy. The newly created Snapshot copy is always selected.

For extended data protection (XDP) relationships with a `snapmirror policy` of type `vault` or `mirror-vault`, the `snapmirror update` command also manages expiration of Snapshot copies on the destination volume. It does so by deleting Snapshot copies that have exceeded the value of `-keep` for the matching rule from the corresponding SnapMirror policy associated with the SnapMirror relationship. Snapshot copies that match the same `-snapmirror-label` will be deleted in oldest-first order.

For relationships with a policy of type `strict-sync-mirror` or `sync-mirror`, this command creates a new common Snapshot copy and designates it as the exported Snapshot copy on the destination volume. It updates the destination read-only view because IO is redirected to the new exported Snapshot copy. Clients could experience a brief latency spike during this process as the primary IO is temporarily fenced. This command is allowed only when the relationship-status is InSync. The command retains two pairs of common Snapshot copies and deletes the older ones.

For data protection relationships, the parameter `-source-snapshot` is optional and only allows for the transfer of Snapshot copies newer than the common Snapshot copy up to the specified `-source-snapshot`.

For extended data protection (XDP) relationships the parameter `-source-snapshot` is optional.

For extended data protection (XDP) relationships with a `snapmirror policy` of type `vault` or `mirror-vault`, the parameter `-source-snapshot` allows transfer of a Snapshot copy that is older than the common Snapshot copy and/or might not be selected for transfer based on policy-based selection of a scheduled update transfer.
For extended data protection (XDP) relationships with a `snapmirror policy` of type `async-mirror`, the `snapmirror update` command with parameter `-source-snapshot` does not create a new Snapshot copy on the source volume. Depending on the rules in the policy, the command might transfer just the specified Snapshot copy or Snapshot copies that are newer than the common Snapshot copy up to and including the specified Snapshot copy to the destination volume.

After the `snapmirror update` command successfully completes, the last Snapshot copy transferred is designated as the new exported Snapshot copy on the destination volume. If an update to an extended data protection (XDP) relationship specifies a Snapshot copy using the `-source-snapshot` parameter that is older than the common snapshot, after the `snapmirror update` successfully completes, the exported Snapshot copy on the destination volume will remain unchanged.

If the `snapmirror update` does not finish successfully—for example, due to a network failure or because a `snapmirror abort` command was issued—a restart checkpoint might be recorded on the destination volume. If a restart checkpoint is recorded, the next update restarts and continues the transfer from the restart checkpoint. For extended data protection (XDP) relationships, the next update will restart and continue the old transfer regardless of whether the Snapshot copy being transferred is a matching Snapshot copy or not.

This command is supported for SnapMirror relationships with the field "Relationship Capability" showing as either "8.2 and above" or "Pre 8.2" in the output of the `snapmirror show` command.

For relationships with "Relationship Capability" of "8.2 and above", you can track the progress of the operation using the `snapmirror show` command.

For relationships with "Relationship Capability" of "Pre 8.2", a job will be spawned to operate on the SnapMirror relationship, and the job id will be shown in the command output. The progress of the job can be tracked using the `job show` and `job history show` commands.

For Vserver SnapMirror relationships, the `snapmirror update` command makes the destination Vserver an up-to-date mirror of the source Vserver.

The `snapmirror update` command must be used from the destination Vserver or cluster.

**Parameters**

```
[-source-path | -S {<[vserver:]|volume> | [cluster://vserver/]volume> |<hostip:/lun/name> |<hostip:/share/share-name>]} - Source Path
```

This parameter specifies the source endpoint of the SnapMirror relationship in one of four path formats. The normal format includes the names of the Vserver (vserver) and/or the volume (volume). To support relationships with "Relationship Capability" of "Pre 8.2", a format which also includes the name of the cluster (cluster) is provided. The "Pre 8.2" format cannot be used when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above". For SnapMirror relationships with an AltaVault source, the source endpoint is specified in the form `hostip:/share/share-name`. For SnapMirror relationships with a SolidFire source, the source endpoint is specified in the form `hostip:/lun/name`.

```
[-source-cluster <Cluster name>] - Source Cluster
```

Specifies the source cluster of the SnapMirror relationship. If this parameter is specified, the `-source-vserver` and `-source-volume` parameters must also be specified. This parameter is only applicable for relationships with "Relationship Capability" of "Pre 8.2". This parameter cannot be specified when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above".

```
[-source-vserver <vserver name>] - Source Vserver
```

Specifies the source Vserver of the SnapMirror relationship. For relationships with volumes as endpoints, if this parameter is specified, parameters `-source-volume` and for relationships with "Relationship Capability" of "Pre 8.2", `-source-cluster` must also be specified. This parameter is not supported for relationships with non-Data ONTAP source endpoints.

```
[-source-volume <volume name>] - Source Volume
```

Specifies the source volume of the SnapMirror relationship. If this parameter is specified, parameters `-source-vserver` and for relationships with "Relationship Capability" of "Pre 8.2", `-source-
cluster must also be specified. This parameter is not supported for relationships with non-Data ONTAP source endpoints.

{-destination-path {<[vserver:][volume]>|<[[cluster://vserver/]]volume>|<hostip:/lun/name> | <hostip:/share/share-name> } - Destination Path

This parameter specifies the destination endpoint of the SnapMirror relationship in one of four path formats. The normal format includes the names of the Vserver (vserver) and/or volume (volume). To support relationships with "Relationship Capability" of "Pre 8.2", a format which also includes the name of the cluster (cluster) is provided. The "Pre 8.2" format cannot be used when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above". For SnapMirror relationships with AltaVault destinations, the destination endpoint is specified in the form hostip:/share/share-name. For relationships with SolidFire destinations, the destination endpoint is specified in the form hostip:/lun/name.

[-destination-cluster <Cluster name>] - Destination Cluster

Specifies the destination cluster of the SnapMirror relationship. If this parameter is specified, parameters -destination-vserver and -destination-volume must also be specified. This parameter is only applicable for relationships with "Relationship Capability" of "Pre 8.2". This parameter cannot be specified when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above".

-destination-vserver <vserver name> - Destination Vserver

Specifies the destination Vserver of the SnapMirror relationship. For relationships with volumes as endpoints, if this parameter is specified, parameters -destination-volume and for relationships with "Relationship Capability" of "Pre 8.2", -destination-cluster must also be specified. This parameter is not supported for relationships with non-Data ONTAP destination endpoints.

-destination-volume <volume name> - Destination Volume

Specifies the destination volume of the SnapMirror relationship. If this parameter is specified, parameters -destination-vserver and for relationships with "Relationship Capability" of "Pre 8.2", -destination-cluster must also be specified. This parameter is not supported for relationships with non-Data ONTAP destination endpoints.

[-source-snapshot | -s <text>] - Source Snapshot

This optional parameter specifies a Snapshot copy to transfer. The default behavior for a data protection relationship with a read-write source is that Data ONTAP creates a new Snapshot copy and uses it as the basis for determining what data are replicated; with this option, the specified Snapshot copy will be used instead. The default behavior for an extended data protection relationship depends on the relationship's policy type. For a data protection relationship, the specified Snapshot copy must be newer than the latest common Snapshot copy. For an extended data protection relationship, the specified Snapshot copy can be newer or older than the common Snapshot copy. This parameter is not supported for relationships with "Relationship Capability" of "Pre 8.2".

[-throttle | -k <throttleType>] - Throttle (KB/sec)

This optional parameter limits the network bandwidth used for the update transfer. It sets the maximum rate (in Kbytes/sec) at which data can be transferred during the operation. If this parameter is not specified, the throttle value configured for the relationship with the snapmirror create or snapmirror modify command will be used. To fully use the network bandwidth available, set the throttle value to unlimited or 0. The minimum throttle value is four Kbytes/sec, so if you specify a throttle value between 1 and 4, it will be treated as if you specified 4. For FlexGroup relationships, the throttle value is applied individually to each constituent relationship. The -throttle parameter does not affect load-sharing transfers and transfers for other relationships with "Relationship Capability" of "Pre 8.2" confined to a single cluster.

[-transfer-priority (low|normal)] - Transfer Priority

This optional parameter specifies the priority at which the transfer runs. The default value for this parameter is the value in the SnapMirror policy associated with this relationship. This parameter is not applicable to relationships with a "Relationship Capability" of "Pre 8.2".
[--enable-storage-efficiency [true]] - Enable Storage Efficient Transfers

This is an optional parameter. For an extended data protection (XDP) relationship that is currently not storage efficient, set this parameter to true to enable storage efficient transfers. Storage efficient in this context refers to both over the wire efficiency and how the data is written to the destination volume. The transfer fails if storage efficiency cannot be achieved. If the transfer succeeds, future transfers will continue being storage efficient as long as it is still feasible, but will not fail if the transfer is not storage efficient. The default value is false. This parameter is not supported for relationships with non-Data ONTAP endpoints.

[--foreground | -w [true]] - Foreground Process

This specifies whether the operation runs as a foreground process. If this parameter is specified, the default setting is true (the operation runs in the foreground). When set to true, the command will not return until the process completes. This parameter is only applicable to relationships with "Relationship Capability" of "Pre 8.2".

Examples

To update the mirror relationship between the destination endpoint vs2.example.com:dept_eng_dp_mirror3 and its source endpoint, type the following command:

```
vs2.example.com::> snapmirror update -destination-path vs2.example.com:dept_eng_dp_mirror3
```

For relationships with "Relationship Capability" of "Pre 8.2", to update the mirror relationship between the destination endpoint cluster2://vs2.example.com/dept_eng_dp_mirror3 and its source endpoint, type the following command:

```
cluster2::> snapmirror update -destination-path cluster2://vs2.example.com/dept_eng_dp_mirror3
```

To update the Vserver SnapMirror relationship between destination endpoint dvs1.example.com: and its source endpoint, type the following command:

```
cluster2::> snapmirror update -destination-path dvs1.example.com:
```

**snapmirror update-ls-set**

Start an incremental load-sharing set transfer

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.
Description

The `snapmirror update-ls-set` command updates a set of load-sharing mirrors. The command makes destination volumes, in the group of load-sharing mirrors, up-to-date mirrors of the source volume.

The key parameter that identifies the set of load-sharing mirrors is the source volume. SnapMirror transfers are performed from the source volume to each of the up-to-date destination volumes in the set of load-sharing mirrors.

The `snapmirror update-ls-set` command performs an incremental transfer to each of the destination volumes. During an incremental transfer, Data ONTAP takes a Snapshot copy on the source volume to capture the current image of the source volume, finds the most recent common Snapshot copy between the source and destination volumes, and incrementally transfers Snapshot copies that are newer than the common Snapshot copy to the destination volume.

**Note:** You still need to use the `snapmirror update-ls-set` command to manually update the set of load-sharing mirrors even if the set only has one destination mirror. The `snapmirror update` command can only be used to bring up to date a specific destination mirror that is lagging to the set.

After an update using the `snapmirror update-ls-set` command successfully completes, the last Snapshot copy transferred is made the new exported Snapshot copy on the destination volumes.

This command is only supported for SnapMirror relationships with the field "Relationship Capability" showing as "Pre 8.2" in the output of the `snapmirror show` command.

Parameters

```
{-source-path | -S <[vserver:]volume> | <[cluster://vserver/]/volume> | <hostip:/lun/name> | <hostip:/share/share-name>} - Source Path
```

This parameter specifies the source endpoint of the SnapMirror relationship in one of four path formats. The normal format includes the names of the Vserver (vserver) and/or the volume (volume). To support relationships with "Relationship Capability" of "Pre 8.2", a format which also includes the name of the cluster (cluster) is provided. The "Pre 8.2" format cannot be used when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above". For SnapMirror relationships with an AltaVault source, the source endpoint is specified in the format `hostip:/share/share-name`. For SnapMirror relationships with a SolidFire source, the source endpoint is specified in the form `hostip:/lun/name`.

```
[-source-cluster <Cluster name>] - Source Cluster
```

Specifies the source cluster of the SnapMirror relationship. If this parameter is specified, the `-source-vserver` and `-source-volume` parameters must also be specified. This parameter is only applicable for relationships with "Relationship Capability" of "Pre 8.2". This parameter cannot be specified when operating in a Vserver context on relationships with "Relationship Capability" of "8.2 and above".

```
-source-vserver <vserver name> - Source Vserver
```

Specifies the source Vserver of the SnapMirror relationship. For relationships with volumes as endpoints, if this parameter is specified, parameters `-source-volume` and for relationships with "Relationship Capability" of "Pre 8.2", `-source-cluster` must also be specified. This parameter is not supported for relationships with non-Data ONTAP source endpoints.

```
-source-volume <volume name> - Source Volume
```

Specifies the source volume of the SnapMirror relationship. If this parameter is specified, parameters `-source-vserver` and for relationships with "Relationship Capability" of "Pre 8.2", `-source-cluster` must also be specified. This parameter is not supported for relationships with non-Data ONTAP source endpoints.

```
[-foreground | -w [true]] - Foreground Process
```

This specifies whether the operation runs as a foreground process. If this parameter is specified, the default setting is `true` (the operation runs in the foreground). When set to `true`, the command will not return until the process completes. This parameter is only applicable to relationships with "Relationship Capability" of "Pre 8.2".
Examples
To update the group of load-sharing mirrors for the source endpoint named //vs1.example.com/dept_eng, type the following command:

```
cluster1::> snapmirror update-ls-set -source-path //vs1.example.com/dept_eng
```

The config-replication directory

**snapmirror config-replication status commands**
SnapMirror configuration replication status information

**snapmirror config-replication status show**
Display SnapMirror configuration replication status information

**Availability**: This command is available to `cluster` administrators at the `admin` privilege level.

**Description**
The `snapmirror config-replication status show` command displays the current SnapMirror configuration replication status.

The command displays the following aspects of SnapMirror configuration replication:

- **Enabled**: Verifies that SnapMirror configuration replication is enabled on the cluster.
- **Running**: Verifies that SnapMirror configuration replication is running on the cluster.
- **Storage Status**: Verifies that SnapMirror configuration replication storage is healthy.
- **Storage In Use**: Prints the location of SnapMirror configuration replication storage.
- **Storage Remarks**: Prints the underlying root cause for non-healthy SnapMirror configuration storage.
- **Vserver Streams**: Verifies that SnapMirror configuration replication Vserver streams are healthy.

Additional information about the warnings (if any) and recovery steps can be viewed by running the command with the `-instance` option.

**Parameters**

```
[-instance ]
```

If you specify the `-instance` parameter, the command displays detailed information about all fields.

**Examples**
The following example shows the execution of the command:

snapmirror config-replication status show-communication on page 718

**snapmirror config-replication status show-aggregate-eligibility**

Display the SnapMirror configuration replication aggregate eligibility

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**

The `snapmirror config-replication status show-aggregate-eligibility` command displays the SnapMirror configuration replication aggregate eligibility.

**Parameters**

`[-fields <fieldname>, ...]`

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

`[-instance ]`

If you specify the `-instance` parameter, the command displays detailed information about all fields.

`[-aggregate <aggregate name>] - Aggregate`

Display only rows that have a matching aggregate name.

`[-hosted-configuration-replication-volumes <volume name>, ...] - Currently Hosted Configuration Replication Volumes`

Display only rows that have matching configuration replication volumes hosted on this aggregate.

`[-is-eligible-to-host-additional-volumes {true|false}] - Eligibility to Host Another Configuration Replication Volume`

Display only rows that have a matching eligibility of the aggregate to host additional configuration replication volumes.

`[-comment <text>] - Comment for Eligibility Status`

Display only rows that have a matching comment regarding the eligibility of the aggregate to host configuration replication volumes.

**Examples**

The following example shows the execution of the command in a SnapMirror configuration with thirteen aggregates in the cluster:

```
clusA::snapmirror config-replication status> show-aggregate-eligibility

Eligible to Host Addl Vols Comments
------------------------------- -----------
a0 false Root Aggregate
a1 MDV_CRS_1bc7134a5ddf11e3b63f123478563412_A true -
a2 MDV_CRS_1bc7134a5ddf11e3b63f123478563412_B true -
a3 false Unable to determine

available space of aggregate
```

snapmirror config-replication status show on page 716

snapmirror config-replication status show-communication

Display SnapMirror configuration replication communication status information

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The snapmirror config-replication status show-communication command displays the current SnapMirror configuration replication communication status.

The command displays the following aspects of SnapMirror configuration replication for each peer cluster:

- Remote Heartbeat: Verifies that the SnapMirror configuration replication heartbeat with the remote cluster is healthy.
- Last Heartbeat Sent: Prints the timestamp of the last SnapMirror configuration replication heartbeat sent to the remote cluster.
- Last Heartbeat Received: Prints the timestamp of the last SnapMirror configuration replication heartbeat received from the remote cluster.

Additional information about the warnings (if any) and recovery steps can be viewed by running the command with the -instance option.

Parameters

```
[-fields <fieldname>, ...]
```

If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

```
[-instance ]
```

If you specify the -instance parameter, the command displays detailed information about all fields.

```
[-cluster-uuid <UUID>] - Remote Cluster
```

Display only rows that have a matching peer cluster UUID.

```
[-cluster <text>] - Peer Cluster Name
```

Display only rows that have matching peer cluster name.

```
[-remote-heartbeat {ok|warning|not-run|not-applicable}] - Remote Heartbeat
```

Display only rows that have a matching remote heartbeat status.

```
[-last-heartbeat-sent <MM/DD/YYYY HH:MM:SS>] - Last Heartbeat Sent Time
```

Display only rows that have a matching timestamp of the last heartbeat sent.
[–last-heartbeat-received <MM/DD/YYYY HH:MM:SS>] - Last Heartbeat Received Time
Display only rows that have a matching timestamp of the last heartbeat received.

[–heartbeat-recovery-steps <text>] - Heartbeat Recovery Steps
Display only rows that have matching heartbeat recovery steps.

**Examples**
The following example shows the execution of the command in a SnapMirror configuration with two peer clusters:

```
clus1:~*> snapmirror config-replication status show-communication
  Peer Cluster: clus2
  Remote Heartbeat: ok
  Last Heartbeat Sent: 11/11/2014 11:11:45
  Last Heartbeat Received: 11/11/2014 11:11:46

  Peer Cluster: clus3
  Remote Heartbeat: ok
  Last Heartbeat Sent: 11/11/2014 11:11:26
  Last Heartbeat Received: 11/11/2014 11:11:27

2 entries were displayed.

The snapmirror config-replication cluster-storage-configuration show command shows details of the configuration of the storage used for configuration replication.

The information displayed is the following:

- Disallowed Aggregates - The list of storage aggregates that are configured as not allowed to host storage areas.
- Auto-Repair - Displays true if the automatic repair of storage areas used by configuration replication is enabled.
- Auto-Recreate - Displays true if the automatic recreation of storage volumes used by configuration replication is enabled.
- Use Mirrored Aggregate - Displays true if storage areas for configuration replication are to be hosted on a mirrored aggregate.

Examples
The following is an example of the snapmirror config-replication cluster-storage-configuration show command:

```bash
cluster1::*> snapmirror config-replication cluster-storage-configuration show
Disallowed Aggregates: -
Auto-Repair: true
Auto-Recreate: true
Use Mirrored Aggregate: true
```

snapmirror object-store commands
The object-store directory

snapmirror object-store profiler commands
The profiler directory

snapmirror object-store profiler abort
Abort Object Store Profiler

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
The snapmirror object-store profiler abort command will abort an ongoing object store profiler run. This command requires two parameters - an object store configuration and a node on which the profiler is currently running.
Parameters

- **node {<nodename>|local}** - Node on Which the Profiler Should Run
  
  This parameter specifies the node on which the object store profiler is running.

- **object-store-name <text>** - Object Store Configuration Name
  
  This parameter specifies the object store configuration that describes the object store. The object store configuration has information about the object store server name, port, access credentials, and provider type.

Examples

The following example aborts the object store profiler:

```
cluster1::>snapmirror object-store profiler abort -object-store-name my-store -node my-node
```

Related references

*storage aggregate object-store profiler abort* on page 885

**snapmirror object-store profiler show**

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

**Description**

The *snapmirror object-store profiler show* command is used to monitor progress and results of the *snapmirror object-store profiler start* command.

**Parameters**

```
[-fields <fieldname>, ...]

If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use ‘-fields ?’ to display the fields to specify.

[-instance]

If you specify the -instance parameter, the command displays detailed information about all fields.
```

- **-node <nodename>** - Node Name
  
  This parameter specifies the node on which the profiler was started.

- **-object-store-name <text>** - ONTAP Name for this Object Store Configuration
  
  This parameter specifies the object store configuration that describes the object store. The object store configuration has information about the object store server name, port, access credentials, and provider type.

- **-profiler-status <text>** - Profiler Status
  
  Current status of the profiler.

- **-start-time <MM/DD/YYYY HH:MM:SS>** - Profiler Start Time
  
  Time at which profiler run started.

- **-op-name <text>** - Operation Name - PUT/GET
  
  Name of the operation. Possible values are PUT or GET.

- **-op-size <integer> [KB|MB|GB|TB|PB]** - Size of Operation
  
  Size of the PUT or GET operation.

- **-op-count <integer>** - Number of Operations Performed
  
  Number of operations issued to the object store.
[-op-failed <integer>] - Number of Operations Failed
   Number of operations that failed.

[-op-latency-minimum <integer>] - Minimum Latency for Operation in Milliseconds
   Minimum latency of the operation in milliseconds, as measured from the filesystem layer.

[-op-latency-maximum <integer>] - Maximum Latency for Operation in Milliseconds
   Maximum latency of the operation in milliseconds, as measured from the filesystem layer.

[-op-latency-average <integer>] - Average Latency for Operation in Milliseconds
   Average latency of the operation in milliseconds, as measured from the filesystem layer.

[-op-throughput {<integer> [KB|MB|GB|TB|PB]}] - Throughput per Second for the operation
   Throughput per second for the operation.

[-op-errors <text>, ...] - Error Reasons and Count
   Error reasons and count for failed operation.

[-op-latency-histogram <text>, ...] - Latency Histogram
   Latency histogram for the operation.

Examples
The following example displays the results of `snapmirror object-store profiler start`:

```
cluster1::>snapmirror object-store profiler show
```

**snapmirror object-store profiler start**

Start the object store profiler to measure latency and throughput

**Availability:** This command is available to cluster administrators at the *advanced* privilege level.

**Description**
The `snapmirror object-store profiler start` command writes objects to an object store and reads those objects to measure latency and throughput of an object store. This command requires two parameters - an object store configuration and node from which to send the PUT/GET/DELETE operations. This command verifies whether the object store is accessible through the intercluster LIF of the node on which it runs. The command fails if the object store is not accessible. The command will create a 10GB dataset by doing 2500 PUTs for a maximum time period of 60 seconds. Then it will issue GET operations of different sizes - 4KB, 8KB, 32KB, 256KB for a maximum time period of 180 seconds. Finally it will delete the objects it created. This command can result in additional charges to your object store account. This is a CPU intensive command. It is recommended to run this command when the system is under 50% CPU utilization.

**Parameters**

- **-node {<nodename>|local}** - Node on Which the Profiler Should Run
  This parameter specifies the node from which PUT/GET/DELETE operations are sent.

- **-object-store-name <text>** - Object Store Configuration Name
  This parameter specifies the object store configuration that describes the object store. The object store configuration has information about the object store server name, port, access credentials, and provider type.
Examples
The following example starts the object store profiler:

```
class1::>snapmirror object-store profiler start -object-store-name my-store -node my-node
```

snapmirror policy commands

Manage SnapMirror policies

The `snapmirror policy` command enables you to manage SnapMirror policies.

**snapmirror policy add-rule**

Add a new rule to SnapMirror policy

**Availability:** This command is available to `cluster` and `Vserver` administrators at the `admin` privilege level.

**Description**

The `snapmirror policy add-rule` command adds a rule to a SnapMirror policy. Rules define which Snapshot copies are protected by vault relationships or define the schedule at which Snapshot copies are created on the SnapMirror destination. Rules which do not include a schedule are rules for protecting Snapshot copies. Rules which include a schedule are rules for creating Snapshot copies on the SnapMirror destination. A rule with a schedule can only be added to SnapMirror policies of type `vault` or `Mirror-vault`. A rule must not be added to a policy that will be associated with a SnapMirror data protection relationship. A policy that will be associated with a SnapMirror vault relationship must have at least one rule and at most ten rules. A SnapMirror policy with rules must have at least one rule without a schedule.

**Parameters**

- `--vserver <vserver_name>` - Vserver Name
  Specifies the Vserver for the SnapMirror policy.

- `--policy <sm_policy>` - SnapMirror Policy Name
  Specifies the SnapMirror policy name.

- `--snapmirror-label <text>` - Snapshot Copy Label
  This parameter is primarily used for the purpose of Snapshot copy selection for extended data protection (XDP) relationships. Only Snapshot copies that have a SnapMirror label that matches this parameter will be transferred to the SnapMirror destination. However, when this parameter is associated with a rule containing a schedule, Snapshot copies will be created on the SnapMirror destination using this snapmirror-label parameter. The label can be 31 or fewer characters in length. SnapMirror policies of type `async-mirror` and `mirror-vault` have a rule added for label `sm_created` at the time of policy creation. This rule cannot be removed or modified by the user. This rule when coupled with `create-snapshot` field set to `true` indicates that the SnapMirror relationship using this policy shall create a new Snapshot copy and transfer it as part of a `snapmirror update` operation. SnapMirror policies of type `async-mirror` support one additional rule with SnapMirror label `all_source_snapshots`. This rule along with the rule for SnapMirror label `sm_created` indicates that all new Snapshot copies on the primary volume along with the newly created Snapshot copy are transferred as a part of a `snapmirror update` or `snapmirror initialize` operation. Rules with any other SnapMirror labels cannot be added to SnapMirror policies of type `async-mirror`. The rule for label `sm_created` when added to a `snapmirror policy` of type `vault` indicates that all SnapMirror created Snapshot copies of the primary volume are selected for transfer.
-keep <text> - Snapshot Copy Retention Count

Specifies the maximum number of Snapshot copies that are retained on the SnapMirror destination volume for a rule. The total number of Snapshot copies retained for all the rules in a policy cannot exceed 1019. For all the rules in SnapMirror policies of type async-mirror, this parameter must be set to value 1.

[-preserve {true|false}] - Snapshot Copy Preserve Enabled

Specifies the behavior when the Snapshot copy retention count is reached on the SnapMirror vault destination for the rule. The default value is false, which means that the oldest Snapshot copy will be deleted to make room for new ones only if the number of Snapshot copies has exceeded the retention count specified in the "keep" parameter. When set to true, and when the Snapshot copies have reached the retention count, then an incremental SnapMirror vault update transfer will fail or if the rule has a schedule, Snapshot copies will no longer be created on the SnapMirror destination. For all the rules in SnapMirror policies of type async-mirror this parameter must be set to value false.

[-warn <integer>] - Warning Threshold Count

Specifies the warning threshold count for the rule. The default value is 0. When set to a value greater than zero, an event is generated after the number of Snapshot copies (for the particular rule) retained on a SnapMirror vault destination reaches the specified warn limit. The preserve parameter for the rule must be true to set the warn parameter to a value greater than zero.

[-schedule <text>] - Snapshot Copy Creation Schedule

This optional parameter specifies the name of the schedule associated with a rule. This parameter is allowed only for rules associated with SnapMirror policies of type vault or mirror-vault. When this parameter is specified, Snapshot copies are directly created on the SnapMirror destination. The Snapshot copies created will have the same content as the latest Snapshot copy already present on the SnapMirror destination. Snapshot copies on the source that have a SnapMirror label matching this rule will not be selected for transfer. The default value is -.

Note: You define and name a schedule using the job schedule cron create command.

[-prefix <text>] - Snapshot Copy Creation Prefix

This optional parameter specifies the prefix for the Snapshot copy name to be created as per the schedule. If no value is specified, then the snapmirror-label will be used as the prefix. The prefix parameter can only be specified for rules which have a schedule.

Examples

The following example adds a rule named nightly to the SnapMirror policy named TieredBackup on Vserver vs0.example.com. The rule will retain a maximum of 5 nightly Snapshot copies.

```
vs0.example.com::> snapmirror policy add-rule -vserver vs0.example.com
-policy TieredBackup -snapmirror-label nightly -keep 5
```

The following example adds a rule named SyncProtectMe to the SnapMirror policy named Smgr on Vserver vs0.example.com. The rule will retain the same SyncProtectMe snapshots on the destination as are present on the source when the relationship is InSync.

```
vs0.example.com::> snapmirror policy add-rule -vserver vs0.example.com
-policy Smgr -snapmirror-label SyncProtectMe -keep 1
```

- snapmirror policy on page 723
- snapmirror resync on page 676
**snapmirror policy create**

Create a new SnapMirror policy

**Availability:** This command is available to cluster and Vserver administrators at the admin privilege level.

**Description**

The `snapmirror policy create` command creates a SnapMirror policy. When applied to a SnapMirror relationship, the SnapMirror policy controls the behavior of the relationship and specifies the configuration attributes for that relationship. The policies `DPDefault`, `MirrorAllSnapshots`, `MirrorAndVault`, `MirrorLatest`, `Unified7year` and `XDPDefault` are created by the system for asynchronous replication. The policies `Sync` and `StrictSync` are created by the system for synchronous replication.

**Note:** All SnapMirror policies have a field `create-snapshot`. This field specifies whether SnapMirror creates a new Snapshot copy on the primary volume at the beginning of a `snapmirror update` or `snapmirror resync` operation. Currently this field cannot be set or modified by the user. It is set to `true` for SnapMirror policies of type `async-mirror` and `mirror-vault` at the time of creation. SnapMirror policies of type `vault` have `create-snapshot` set to `false` at the time of creation.

**Note:** Use the `snapmirror policy add-rule` command to add a rule to a policy.

**Parameters**

- `vserver <vserver name>` - Vserver Name
  
  Specifies the Vserver for the SnapMirror policy.

- `policy <sm_policy>` - SnapMirror Policy Name
  
  This parameter specifies the SnapMirror policy name. A policy name can be made up of the characters A to Z, a to z, 0 to 9, ",", "-", and "_". The name can be up to 256 characters in length.

- `[-type {vault|async-mirror|mirror-vault|strict-sync-mirror|sync-mirror}]` - SnapMirror Policy Type
  
  This parameter specifies the SnapMirror policy type. The supported values are `async-mirror`, `vault`, `mirror-vault`, `sync-mirror` and `strict-sync-mirror`. Data protection (DP) relationships support only `async-mirror` policy type, while extended data protection (XDP) relationships support all policy types.

  If the type is set to `async-mirror` then the policy is for Disaster Recovery. When the policy type is associated with extended data protection (XDP) relationships, `snapmirror update` and `snapmirror resync` operations transfer selected Snapshot copies from the primary volume to the secondary volume. The selection of Snapshot copies is governed by the rules in the policy. However `snapmirror initialize` and `snapmirror update` operations on data protection (DP) relationships ignore the rules in the policy and transfer all Snapshot copies of the primary volume which are newer than the common Snapshot copy on the destination. For both data protection (DP) and extended data protection (XDP) relationships, the Snapshot copies are kept on the secondary volume as long as they exist on the primary volume. Once a protected Snapshot copy is deleted from the primary volume, it is deleted from the secondary volume as part of the next transfer. The policy type supports rules with certain pre-defined label names only. Refer to the man page for the `snapmirror policy add-rule` command for the details.

  If the type is set to `vault` then the policy is used for Backup and Archive. The rules in this policy type determine which Snapshot copies are protected and how long they are retained on the secondary volume. This policy type is supported by extended data protection (XDP) relationships only.

  If the type is set to `mirror-vault` then the policy is used for unified data protection which provides both Disaster Recovery and Backup using the same secondary volume. This policy type is supported by extended data protection (XDP) relationships only.
If the type is set to `sync-mirror` or `strict-sync-mirror` then the policy is used for synchronous Disaster Recovery. These are supported only by extended data protection (XDP) relationships between FlexVol volumes. Once the relationship is initialized with `snapmirror initialize`, the relationship will be InSync such that all writes to the primary will be replicated to the secondary before the write is acknowledged to the client. Upon a replication failure, relationship falls OutOfSync. Upon an OutOfSync event, the `strict-sync-mirror` variant restricts further client IO on the primary, whereas the `sync-mirror` variant does not. SnapMirror will automatically trigger resync to bring the OutOfSync relationships back InSync as soon as it can, unless the relationship is `Quiesced` or `Broken-off`. Once a relationship is initialized, you normally use the `snapmirror quiesce` command to stop synchronous replication and the `snapmirror resume` command to resume synchronous replication. These policy types do not support replication of user Snapshot copies.

```
[-comment <text>] - Comment
  Specifies a text comment for the SnapMirror policy. If the comment contains spaces, it must be enclosed within quotes.

[-tries <unsigned32_or_unlimited>] - Tries Limit
  Determines the maximum number of times to attempt each manual or scheduled transfer for a SnapMirror relationship. The value of this parameter must be a positive integer or `unlimited`. The default value is 8.

[-transfer-priority {low|normal}] - Transfer Scheduling Priority
  Specifies the priority at which a transfer runs. The supported values are `normal` or `low`. The `normal` transfers are scheduled before the `low` priority transfers. The default is `normal`.

[-ignore-atime {true|false}] - Ignore File Access Time
  This parameter applies only to extended data protection (XDP) relationships. It specifies whether incremental transfers will ignore files which have only their access time changed. The supported values are `true` or `false`. The default is `false`.

[-restart {always|never|default}] - Restart Behavior
  This parameter applies only to data protection relationships. It defines the behavior of SnapMirror if an interrupted transfer exists. The supported values are `always`, `never`, or `default`. If the value is set to `always`, an interrupted SnapMirror transfer always restarts provided it has a restart checkpoint and the conditions are the same as they were before the transfer was interrupted. In addition, a new SnapMirror Snapshot copy is created which will then be transferred. If the value is set to `never`, an interrupted SnapMirror transfer will never restart, even if a restart checkpoint exists. A new SnapMirror Snapshot copy will still be created and transferred. Data ONTAP version 8.2 will interpret a value of `default` as being the same as `always`. Vault transfers will always resume based on a restart checkpoint, provided the Snapshot copy still exists on the source volume.

[-is-network-compression-enabled {true|false}] - Is Network Compression Enabled
  Specifies whether network compression is enabled for transfers. The supported values are `true` or `false`. The default is `false`.

[-common-snapshot-schedule <text>] - Common Snapshot Copy Creation Schedule for SnapMirror Synchronous (privilege: advanced)
  Specifies the common Snapshot creating schedule. This parameter is only supported for SnapMirror Synchronous relationships.

[-are-data-ops-sequentially-split {true|false}] - Is Sequential Splitting of Data Operations Enabled?
  This parameter specifies whether I/O, such as write, copy-offload and punch-holes, are split sequentially, rather than being run in parallel on the source and destination. Splitting I/O sequentially will make the system more robust, and less prone to I/O errors. However, it will also make I/O performance slower. The default value for the parameter `-are-data-ops-sequentially-split` is `false`. The parameter `-are-data-ops-sequentially-split` should only be used if too frequent I/O timeout or OutOfSync has happened.
  The parameter `-are-data-ops-sequentially-split` requires an effective cluster version of Data ONTAP 9.6.0 or later on both the source and destination clusters.
[\(-\text{discard-configs } \langle\text{network}\rangle, ...\) - Configurations Not Replicated During Identity Preserve Vserver DR

Specifies the configuration to be dropped during replication. The supported values are:

- \(\text{network}\) - Drops network interfaces, routes, and kerberos configuration.

This parameter is supported only for policies of type \(\text{async-mirror}\) and applicable only for identity-preserve Vserver SnapMirror relationships.

**Examples**

The following example creates a SnapMirror policy named \(\text{TieredBackup}\) on a Vserver named \(\text{vs0.example.com}\).

```
vs0.example.com::> snapmirror policy create -vserver vs0.example.com
  -policy TieredBackup -type vault -tries 10 -restart never
```

The following example executed under PVR control creates a SnapMirror policy named \(\text{Sync}\) on a Vserver named \(\text{vs0.example.com}\) with \(-\text{always-replicate_snapshots}\) set to \(\text{true}\) to be used for a relationship between items in Consistency Groups.

```
vs0.example.com::> snapmirror policy create -vserver vs0.example.com
  -policy Smgr -type smgr-mirror -always-replicate-snapshots true
```

**snapmirror policy delete**

Delete a SnapMirror policy

**Availability:** This command is available to cluster and Vserver administrators at the \(\text{admin}\) privilege level.

**Description**

The `snapmirror policy delete` command deletes a SnapMirror policy. A policy that is to be deleted must not be associated with any SnapMirror relationship. The built-in policies cannot be deleted.

**Parameters**

- `-vserver <vserver name>` - Vserver Name
  
  Specifies the Vserver for the SnapMirror policy.

- `-policy <sm_policy>` - SnapMirror Policy Name
  
  Specifies the SnapMirror policy name.

**Examples**

The following example deletes a SnapMirror policy named \(\text{TieredBackup}\) on Vserver \(\text{vs0.example.com}\):
snapmirror policy modify

Modify a SnapMirror policy

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The snapmirror policy modify command can be used to modify the policy attributes.

Note: Use the snapmirror policy modify-rule command to modify a rule in a SnapMirror policy.

Parameters
-vserver <vserver name> - Vserver Name
  Specifies the Vserver for the SnapMirror policy.

-policy <sm_policy> - SnapMirror Policy Name
  Specifies the SnapMirror policy name.

[-comment <text>] - Comment
  Specifies a text comment for the SnapMirror policy. If the comment contains spaces, it must be enclosed within quotes.

[-tries <unsigned32_or_unlimited>] - Tries Limit
  Determines the maximum number of times to attempt each manual or scheduled transfer for a SnapMirror relationship. The value of this parameter must be a positive integer or unlimited. The default value is 8.

[-transfer-priority {low|normal}] - Transfer Scheduling Priority
  Specifies the priority at which a transfer runs. The supported values are normal or low. The normal transfers are scheduled before the low priority transfers. The default is normal.

[-ignore-atime {true|false}] - Ignore File Access Time
  This parameter applies only to extended data protection (XDP) relationships. It specifies whether incremental transfers will ignore files which have only their access time changed. The supported values are true or false. The default is false.

[-restart {always|never|default}] - Restart Behavior
  This parameter applies only to data protection relationships. It defines the behavior of SnapMirror if an interrupted transfer exists. The supported values are always, never, or default. If the value is set to always, an interrupted SnapMirror transfer always restarts provided it has a restart checkpoint and the conditions are the same as they were before the transfer was interrupted. In addition, a new SnapMirror Snapshot copy is created which will then be transferred. If the value is set to never, an interrupted SnapMirror transfer will never restart, even if a restart checkpoint exists. A new SnapMirror Snapshot copy will still be created and transferred. Data ONTAP version 8.2 will interpret a value of default as being the same as always. Vault transfers will always resume based on a restart checkpoint, provided the Snapshot copy still exists on the source volume.

[-is-network-compression-enabled {true|false}] - Is Network Compression Enabled
  Specifies whether network compression is enabled for transfers. The supported values are true or false. The default is false.
[common-snapshot-schedule <text>] - Common Snapshot Copy Creation Schedule for SnapMirror
Synchronous (privilege: advanced)

Specifies the common Snapshot creating schedule. This parameter is only supported for Snapmirror Synchronous relationships.

[are-data-ops-sequentially-split {true|false}] - Is Sequential Splitting of Data Operations Enabled?

This parameter specifies whether I/O, such as write, copy-offload and punch-holes, are split sequentially, rather than being run in parallel on the source and destination. Splitting the I/O sequentially will make the system more robust, and less prone to I/O errors. However, it will also make I/O performance slower. The default value of parameter -sequential-split-data-ops is false. The parameter -are-data-ops-sequentially-split should only be used if too frequent I/O timeout or OutOfSync has happened. Changes made by the snapmirror policy modify -sequential-split-data-ops command do not take effect until the next resync. Changes do not affect resync or initialize operations that have started and have not finished yet. The parameter -are-data-ops-sequentially-split requires an effective cluster version of Data ONTAP 9.6.0 or later on both the source and destination clusters.

[discard-configs <network>, ...] - Configurations Not Replicated During Identity Preserve Vserver DR

Specifies the configuration to be dropped during replication. The supported values are:

* network - Drops network interfaces, routes, and kerberos configuration.

This parameter is supported only for policies of type async-mirror and applicable only for identity-preserve Vserver SnapMirror relationships.

Examples

The following example changes the "transfer-priority" and the "comment" text of a snapmirror policy named TieredBackup on Vserver vs0.example.com:

```
vs0.example.com::> snapmirror policy modify -vserver vs0.example.com -policy TieredBackup -transfer-priority low -comment "Use for tiered backups"
```

Related references

snapmirror update on page 710
snapmirror initialize on page 647
snapmirror policy on page 723
snapmirror resync on page 676
job schedule cron create on page 163
snapmirror policy modify-rule on page 729

snapmirror policy modify-rule

Modify an existing rule in SnapMirror policy

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description

The snapmirror policy modify-rule command can be used to modify the retention count, preserve setting, warning threshold count, schedule, and prefix for a rule in a SnapMirror policy. Reducing the retention count or disabling the preserve setting for a rule in a SnapMirror policy might result in the deletion of Snapshot copies on the vault destination when the next transfer by the snapmirror update command occurs or when the next scheduled Snapshot copy creation on the destination for the rule occurs. Modifying a rule to add a schedule will enable creation of Snapshot copies on the SnapMirror destination. Snapshot copies on the source that have a SnapMirror label matching this rule will not be selected for transfer. Schedule and prefix can only be modified for rules associated with SnapMirror policies of type vault or mirror-vault. A SnapMirror policy with rules must have at least one rule without a schedule.
Note: The rules in SnapMirror policies of type async-mirror cannot be modified.

Parameters
-vserver <vserver name> - Vserver Name
   Specifies the Vserver for the SnapMirror policy.

-policy <sm_policy> - SnapMirror Policy Name
   Specifies the SnapMirror policy name.

-snapmirror-label <text> - Snapshot Copy Label
   This parameter specifies the rule that is to be modified in a SnapMirror policy.

[keep <text>] - Snapshot Copy Retention Count
   Specifies the maximum number of Snapshot copies that are retained on the SnapMirror destination volume for a rule. The total number of Snapshot copies retained for all the rules in a policy cannot exceed 1019. For all the rules in SnapMirror policies of type async-mirror, this parameter must be set to value 1.

[preserve {true|false}] - Snapshot Copy Preserve Enabled
   Specifies the behavior when the Snapshot copy retention count is reached on the SnapMirror vault destination for the rule. The default value is false, which means that the oldest Snapshot copy will be deleted to make room for new ones only if the number of Snapshot copies has exceeded the retention count specified in the "keep" parameter. When set to true, and when the Snapshot copies have reached the retention count, then an incremental SnapMirror vault update transfer will fail or if the rule has a schedule, Snapshot copies will no longer be created on the SnapMirror destination. For all the rules in SnapMirror policies of type async-mirror, this parameter must be set to value false.

[warn <integer>] - Warning Threshold Count
   Specifies the warning threshold count for the rule. The default value is 0. When set to a value greater than zero, an event is generated after the number of Snapshot copies (for the particular rule) retained on a SnapMirror vault destination reaches the specified warn limit. The preserve parameter for the rule must be true to set the warn parameter to a value greater than zero.

[schedule <text>] - Snapshot Copy Creation Schedule
   This optional parameter specifies the name of the schedule associated with a rule. This parameter is allowed only for rules associated with SnapMirror policies of type vault or mirror-vault. When this parameter is specified, Snapshot copies are directly created on the SnapMirror destination. The Snapshot copies created will have the same content as the latest Snapshot copy already present on the SnapMirror destination. Snapshot copies on the source that have a SnapMirror label matching this rule will not be selected for transfer. The default value is -.

   Note: You define and name a schedule using the job schedule cron create command.

[prefix <text>] - Snapshot Copy Creation Prefix
   This optional parameter specifies the prefix for the Snapshot copy name to be created as per the schedule. If no value is specified, then the snapmirror-label will be used as the prefix. The prefix parameter can only be specified for rules which have a schedule.

Examples
The following example changes the retention count for nightly Snapshot copies to 6 for a rule named nightly on a SnapMirror policy named TieredBackup on Vserver vs0.example.com:

vs0.example.com::> snapmirror policy modify-rule -vserver vs0.example.com
   -policy TieredBackup -snapmirror-label nightly -keep 6
snapmirror policy remove-rule

Remove a rule from SnapMirror policy

**Availability:** This command is available to cluster and Vserver administrators at the admin privilege level.

**Description**
The `snapmirror policy remove-rule` command removes a rule from a SnapMirror policy. On the destination of a SnapMirror relationship with `snapmirror policy` of type `vault` or `mirror-vault`, all Snapshot copies with a SnapMirror label matching the rule being removed are no longer processed by SnapMirror and might need to be deleted manually. A `snapmirror policy` of type `vault` must have at least one rule if that policy is associated with a SnapMirror relationship. A SnapMirror policy with rules must have at least one rule without a schedule.

**Parameters**
- `-vserver <vserver name>` - Vserver Name
  Specifies the Vserver for the SnapMirror policy.
- `-policy <sm_policy>` - SnapMirror Policy Name
  Specifies the SnapMirror policy name.
- `-snapmirror-label <text>` - Snapshot Copy Label
  This parameter specifies the rule that is removed from the SnapMirror policy.
  The rule for SnapMirror label `sm_created` cannot be removed from SnapMirror policies of type `async-mirror` or `mirror-vault`.

**Examples**
The following example removes a rule named `nightly` from a SnapMirror policy named `TieredBackup` on Vserver `vs0.example.com`:

```
vs0.example.com::> snapmirror policy remove-rule -vserver vs0.example.com -policy TieredBackup -
snapmirror-label nightly
```

**Related references**

• Tries
• Transfer Priority
• Comment for the policy
• Individual Rule Names
• Keep value for the Rule
• Total of Keep values across all Rules in the policy

Parameters

[-fields <fieldname>, ...]
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use -fields ? to display the fields to specify.

[-instance]
If you specify the -instance parameter, the command displays detailed information about all fields.

[-vserver <vserver name>] - Vserver Name
Selects the policies that match this parameter value.

[-policy <sm_policy>] - SnapMirror Policy Name
Selects the policies that match this parameter value.

[-type {vault|async-mirror|mirror-vault|strict-sync-mirror|sync-mirror}] - Snapmirror Policy Type
Selects the policies that match this parameter value. A policy can be of type async-mirror, vault or mirror-vault.

[-owner {cluster-admin|vserver-admin}] - Owner of the Policy
Selects the policies that match this parameter value. A policy can be owned by either the "Cluster Admin" or a "Vserver Admin".

[-comment <text>] - Comment
Selects the policies that match this parameter value.

[-tries <unsigned32_or_unlimited>] - Tries Limit
Selects the policies that match this parameter value.

[-transfer-priority {low|normal}] - Transfer Scheduling Priority
Selects the policies that match this parameter value.

[-ignore-atime {true|false}] - Ignore File Access Time
Selects the policies that match this parameter value.

[-restart {always|never|default}] - Restart Behavior
Selects the policies that match this parameter value.

[-is-network-compression-enabled {true|false}] - Is Network Compression Enabled
Selects the policies that match this parameter value.

[-create-snapshot {true|false}] - Create a New Snapshot Copy
Selects the policies that match this parameter value.

[-snapmirror-label <text>, ...] - Snapshot Copy Label
Selects the policies that match this parameter value.

[-keep <text>, ...] - Snapshot Copy Retention Count
Selects the policies that match this parameter value.
[-preserve {true|false},...] - Snapshot Copy Preserve Enabled
Selects the policies that match this parameter value.

[-warn <integer>,...] - Warning Threshold Count
Selects the policies that match this parameter value.

[-schedule <text>,...] - Snapshot Copy Creation Schedule
Selects the policies that match this parameter value.

[-prefix <text>,...] - Snapshot Copy Creation Prefix
Selects the policies that match this parameter value.

[-total-rules <integer>] - Total Rules in the Policy
Selects the policies that match this parameter value.

[-total-keep <integer>] - Total Retention Count for All Rules in the Policy
Selects the policies that match this parameter value.

[-common-snapshot-schedule <text>] - Common Snapshot Copy Creation Schedule for SnapMirror
Synchronous (privilege: advanced)
Selects the policies that match this parameter value.

[-are-data-ops-sequentially-split {true|false}] - Is Sequential Splitting of Data Operations Enabled?
Selects the policies that match this parameter value.

[-discard-configs <network>,...] - Configurations Not Replicated During Identity Preserve Vserver DR
Selects the policies that match this parameter value.

Examples
The following example displays information about all SnapMirror policies:

cs::> snapmirror policy show
Vaer Policy       Policy Number   Transfer
Name    Name               Type   Of Rules Tries Priority Comment
------- ------------------ ------ -------- ----- -------- ----------
 cs      DPDefault          async-mirror  2     8  normal  Asynchronous SnapMirror policy for
 mirroring all Snapshot copies and the latest active file system.
 SnapMirror Label: sm_created
 all_source_snapshots

0s        MirrorLatest normal
0s        TieredBackup normal
0s        Unified7year normal
0s        XDPDefault normal
7 entries were displayed.
```

**snapmirror snapshot-owner commands**

Manage Snapshot Copy Preservation

The `snapmirror snapshot-owner` command enables management of user-created owners for a Snapshot copy.

**snapmirror snapshot-owner create**

Add an owner to preserve a Snapshot copy for a SnapMirror mirror-to-vault cascade configuration

**Availability:** This command is available to `cluster` and `Vserver` administrators at the `admin` privilege level.

**Description**

The `snapmirror snapshot-owner create` command adds an owner on the specified Snapshot copy. A Snapshot copy can have at most one owner. An owner can only be added to a Snapshot copy on a read-write volume. The Snapshot copy must have a valid SnapMirror label.

**Note:** Refer to the ONTAP Data Protection Guide for valid use cases to add an owner on a Snapshot copy.

**Parameters**

- `vserver <vserver name>` - Vserver Name
  This parameter specifies the Vserver on which the volume is located.

- `volume <volume name>` - Volume Name
  This parameter specifies the name of the volume.

- `snapshot <snapshot name>` - Snapshot Copy Name
  This parameter specifies the name of the Snapshot copy.
[-owner <owner name>] - Snapshot Copy Owner Name

This parameter specifies the name of the owner for the Snapshot copy. The owner name can be made up of the characters A to Z, a to z, 0 to 9, and "_". The name can be up to 32 characters in length. When not specified, an owner will be added with a system-generated default name.

Examples

The following example adds owner app1 on Snapshot copy snap1 on volume voll in Vserver vs0.example.com.

```
cluster1::> snapmirror snapshot-owner create -vserver vs0.example.com
          -volume voll -snapshot snap1 -owner app1
```

The following example adds a default owner on Snapshot copy snap2 on volume voll in Vserver vs0.example.com.

```
cluster1::> snapmirror snapshot-owner create -vserver vs0.example.com
          -volume voll -snapshot snap2
```

snapmirror snapshot-owner delete

Delete an owner used to preserve a Snapshot copy for a SnapMirror mirror-to-vault cascade configuration

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The snapmirror snapshot-owner delete command removes an owner on the specified Snapshot copy, which was added using the snapmirror snapshot-owner create command.

Parameters
-vserver <vserver name> - Vserver Name
This parameter specifies the Vserver on which the volume is located.

-volume <volume name> - Volume Name
This parameter specifies the name of the volume.

-snapshot <snapshot name> - Snapshot Copy Name
This parameter specifies the name of the Snapshot copy.

[-owner <owner name>] - Snapshot Copy Owner Name
This parameter specifies the name of the owner for the Snapshot copy. When not specified, the owner with the system-generated default name will be removed.

Examples

The following example removes owner app1 on Snapshot copy snap1 on volume voll in Vserver vs0.example.com.

```
cluster1::> snapmirror snapshot-owner delete -vserver vs0.example.com
          -volume voll -snapshot snap1 -owner app1
```

The following example removes the default owner on Snapshot copy snap2 on volume voll in Vserver vs0.example.com.

```
cluster1::> snapmirror snapshot-owner delete -vserver vs0.example.com
          -volume voll -snapshot snap2
```
snapmirror snapshot-owner show

Display Snapshot Copies with Owners

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
The snapmirror snapshot-owner show command is used to list all Snapshot copies with owners that were added using the snapmirror snapshot-owner create command.

Parameters

{-fields <fieldname>,...}
If this parameter is specified, the command displays information about the specified fields.

|{-instance}|
If this parameter is specified, the command displays detailed information about all fields.

-vserver <vserver name> - Vserver Name
This parameter specifies the Vserver on which the volume is located.

-volume <volume name> - Volume Name
This parameter specifies the name of the volume.

[-snapshot <snapshot name>] - Snapshot Copy Name
If this parameter is specified, the command displays the owner name for the specified Snapshot copy.

Examples
The following example lists all Snapshot copies with owners on volume vol1 in Vserver vs0. The system-generated default owner name is displayed as "-".

<table>
<thead>
<tr>
<th>Vserver</th>
<th>Volume</th>
<th>Snapshot</th>
<th>Owner Names</th>
</tr>
</thead>
<tbody>
<tr>
<td>vs0.example.com</td>
<td>vol1</td>
<td>snap2</td>
<td>-</td>
</tr>
<tr>
<td></td>
<td></td>
<td>snap1</td>
<td>app1</td>
</tr>
</tbody>
</table>

The following example displays the owner name for Snapshot copy snap1 on volume vol1 in Vserver vs0.example.com.

statistics-v1 commands

The statistics-v1 directory

statistics-v1 nfs commands

Monitor NFS statistics

statistics-v1 nfs show-mount

Display mount statistics

Availability: This command is available to cluster administrators at the advanced privilege level.

Description

The statistics-v1 nfs show-mount command displays the following statistics about the NFS mounts on each node in the cluster:

• Result of the operations (success or failure)
• Total number of null operations
• Total number of mount operations
• Total number of dump operations
• Total number of unmount operations
• Total number of unmountall operations
• Total number of export operations
• Total number of exportall operations
• Total number of pathconf operations
• Total number of all the above operations

This command is designed to be used to analyze performance characteristics and to help diagnose issues.

Parameters

{-fields <fieldname>, ...}

If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

[-instance]

If you specify the -instance parameter, the command displays detailed information about all fields.

[-node {<nodename> | local}] - Node

If you specify this parameter, the command displays statistics only for the specified node.

[-result (success | failure | all)] - Result

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified result (success/failure/all).
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of null operations.

- **mount <Counter with Delta>** - Mount Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of mount operations.

- **dump <Counter with Delta>** - Dump Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of dump operations.

- **unmnt <Counter with Delta>** - UnMount Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of unmount operations.

- **unmntall <Counter with Delta>** - UnMountAll Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of unmountall operations.

- **export <Counter with Delta>** - Export Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of export operations.

- **exportall <Counter with Delta>** - ExportAll Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of exportall operations.

- **pathconf <Counter with Delta>** - PathConf Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of pathconf operations.

- **total <Counter64 with Delta>** - Total Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of total operations.

### Examples

The following example displays statistics about the NFS mounts for a node named node1:

```
cluster1::*> statistics-v1 nfs show-mount -node node1

<table>
<thead>
<tr>
<th>Node</th>
<th>Value</th>
<th>Delta</th>
</tr>
</thead>
<tbody>
<tr>
<td>node1</td>
<td></td>
<td>success</td>
</tr>
<tr>
<td>Null Ops:</td>
<td>2</td>
<td>0/s:16s</td>
</tr>
<tr>
<td>Mount Ops:</td>
<td>1</td>
<td>0/s:16s</td>
</tr>
<tr>
<td>Dump Ops:</td>
<td>0</td>
<td></td>
</tr>
<tr>
<td>Unmount Ops:</td>
<td>1</td>
<td>0/s:16s</td>
</tr>
<tr>
<td>Unmount All Ops:</td>
<td>0</td>
<td></td>
</tr>
<tr>
<td>Export Ops:</td>
<td>0</td>
<td></td>
</tr>
<tr>
<td>ExportAll Ops:</td>
<td>0</td>
<td></td>
</tr>
<tr>
<td>PathConf Ops:</td>
<td>0</td>
<td></td>
</tr>
<tr>
<td>Total Ops:</td>
<td>4</td>
<td>0/s:16s</td>
</tr>
</tbody>
</table>
```

Node      | Value | Delta       |
-----------|-------|-------------|
node1      |       | failure     |
Null Ops:  | 0     |             |
Mount Ops: | 0     |             |
Dump Ops:  | 0     |             |
Unmount Ops: | 0 |             |
Unmount All Ops: | 0 |             |
statistics-v1 nfs show-nlm

(DEPRECATED)-Display NLM statistics

**Availability:** This command is available to cluster administrators at the advanced privilege level.

**Description**
The `statistics-v1 nfs show-nlm` command displays the following statistics about the Network Lock Manager (NLM) on each node in the cluster:

- Result of the operations (success or failure)
- Total number of null operations
- Total number of test operations
- Total number of lock operations
- Total number of cancel operations
- Total number of unlock operations
- Total number of granted operations
- Total number of share operations
- Total number of unshare operations
- Total number of nmlock operations
- Total number of freeall operations
- Total number of all the above operations

This command is designed to be used to analyze performance characteristics and to help diagnose issues.

**Note:** This command requires an effective cluster version earlier than Data ONTAP 9.0. Data for nodes running Data ONTAP 9.0 or later is not collected, and will not be displayed. Use the `statistics show-object nlm` command instead.

**Parameters**

```
[-fields <fieldname>,...]
```

If you specify the `-fields <fieldname>,...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

```
[-instance]
```

If you specify the `-instance` parameter, the command displays detailed information about all fields.

```
[-node <nodename>|local] - Node
```

If you specify this parameter, the command displays statistics only for the specified node.

```
[-result {success|failure|all}] - Result
```

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified result (success/failure/all).
[-null <Counter with Delta>] - Null Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of null operations.

[-test <Counter with Delta>] - Test Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of test operations.

[-lock <Counter with Delta>] - Lock Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of lock operations.

[-cancel <Counter with Delta>] - Cancel Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of cancel operations.

[-unlock <Counter with Delta>] - Unlock Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of unlock operations.

[-granted <Counter with Delta>] - Granted Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of granted operations.

[-share <Counter with Delta>] - Share Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of share operations.

[-unshare <Counter with Delta>] - Unshare Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of unshare operations.

[-nmlock <Counter with Delta>] - NmLock Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of nmlock operations.

[-freeall <Counter with Delta>] - FreeAll Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of freeall operations.

[-total <Counter64 with Delta>] - Total Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of total operations.

Examples
The following example displays statistics about the NLM for a node named node1:

```bash
cluster1::*> statistics-v1 nfs show-nlm -node node1
```

<table>
<thead>
<tr>
<th>Node</th>
<th>Value</th>
<th>Delta</th>
</tr>
</thead>
<tbody>
<tr>
<td>node1</td>

**statistics-v1 nfs show-statusmon**

Display status monitor statistics

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

**Description**

The `statistics-v1 nfs show-statusmon` command displays the following statistics about the Status Monitor on each node in the cluster:

- Result of the operations (success or failure)
- Total number of null operations
- Total number of stat operations
- Total number of monitor operations
- Total number of unmonitor operations
- Total number of unmonitor all operations
- Total number of simucrash operations
- Total number of notify operations
- Total number of all the above operations

This command is designed to be used to analyze performance characteristics and to help diagnose issues.

**Parameters**

```
[-fields <fieldname>, ...]
```

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

```
[-instance]
```

If you specify the `-instance` parameter, the command displays detailed information about all fields.

```
[-node {<nodename>|local]} - Node
```

If you specify this parameter, the command displays statistics only for the specified node.
[-result {success|failure|all}] - Result

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified result (success/failure/all).

[-null <Counter with Delta>] - Null Operations

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of null operations.

[-stat <Counter with Delta>] - Stat Operations

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of stat operations.

[-monitor <Counter with Delta>] - Monitor Operations

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of monitor operations.

[-unmonitor <Counter with Delta>] - Unmonitor Operations

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of unmonitor operations.

[-unmonall <Counter with Delta>] - Unmonitor All Operations

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of unmonitor all operations.

[-simucrash <Counter with Delta>] - SimuCrash Operations

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of simucrash operations.

[-notify <Counter with Delta>] - Notify Operations

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of notify operations.

[-total <Counter64 with Delta>] - Total Operations

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of total operations.

statistics-v1 nfs show-v3

Display NFSv3 statistics

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The statistics-v1 nfs show-v3 command displays the following statistics about the NFSv3 operations on each node in the cluster:

• Result of the operations (success or failure)
• Total number of null operations
• Total number of getattr operations
• Total number of setattr operations
• Total number of lookup operations
• Total number of access operations
• Total number of read symlink operations
• Total number of read operations
• Total number of write operations
• Total number of create operations
• Total number of mkdir operations
• Total number of symlink operations
• Total number of mknod operations
• Total number of remove operations
• Total number of rmdir operations
• Total number of rename operations
• Total number of link operations
• Total number of readdir operations
• Total number of readdirplus operations
• Total number of fsstat operations
• Total number of fsinfo operations
• Total number of pathconf operations
• Total number of commit operations
• Total number of nfsv3 operations
• Percent of null operations
• Percent of getattr operations
• Percent of setattr operations
• Percent of lookup operations
• Percent of access operations
• Percent of readsymlink operations
• Percent of read operations
• Percent of write operations
• Percent of create operations
• Percent of mkdir operations
• Percent of symlink operations
• Percent of mknod operations
• Percent of remove operations
• Percent of rmdir operations
• Percent of rename operations
• Percent of link operations
• Percent of readdir operations
• Percent of readdirplus operations
• Percent of readdir operations
• Percent of readdirplus operations
• Percent of fsstat operations
• Percent of fsinfo operations
• Percent of pathconf operations
• Percent of commit operations

This command is designed to be used to analyze performance characteristics and to help diagnose issues.

**Parameters**

`[-fields <fieldname>, ...]`

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

`[-instance]`

If you specify the `-instance` parameter, the command displays detailed information about all fields.

`[-node <nodename>|local]` - Node

If you specify this parameter, the command displays NFSv3 statistics only for the specified node.

`[-result {success|failure|all}]` - Result

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified result (success/failure/all).

`[-null <Counter with Delta>]` - Null Operations

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of null operations.

`[-gattr <Counter with Delta>]` - GetAttr Operations

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of getattr operations.
[-sattr <Counter with Delta>] - SetAttr Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of setattr operations.

[-lookup <Counter with Delta>] - LookUp Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of lookup operations.

[-access <Counter with Delta>] - Access Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of access operations.

[-rsym <Counter with Delta>] - ReadSymlink Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of readsymlink operations.

[-read <Counter with Delta>] - Read Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of read operations.

[-write <Counter with Delta>] - Write Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of write operations.

[-create <Counter with Delta>] - Create Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of create operations.

[-mkdir <Counter with Delta>] - MkDir Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of mkdir operations.

[-symln <Counter with Delta>] - SymLink Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of symlink operations.

[-mknod <Counter with Delta>] - MkNod Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of mknod operations.

[-remove <Counter with Delta>] - Remove Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of remove operations.

[-rmdir <Counter with Delta>] - RmDir Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of rmdir operations.

[-rename <Counter with Delta>] - Rename Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of rename operations.

[-link <Counter with Delta>] - Link Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of link operations.

[-rdir <Counter with Delta>] - ReadDir Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of readdir operations.
[-rdirp <Counter with Delta>] - ReadDirPlus Operations
    If you specify this parameter, the command displays statistics only about the node or nodes that have the
    specified number of readdirplus operations.

[-fsstat <Counter with Delta>] - FsStat Operations
    If you specify this parameter, the command displays statistics only about the node or nodes that have the
    specified number of fsstat operations.

[-fsinfo <Counter with Delta>] - FsInfo Operations
    If you specify this parameter, the command displays statistics only about the node or nodes that have the
    specified number of fsinfo operations.

[-pconf <Counter with Delta>] - PathConf Operations
    If you specify this parameter, the command displays statistics only about the node or nodes that have the
    specified number of pathconf operations.

[-commit <Counter with Delta>] - Commit Operations
    If you specify this parameter, the command displays statistics only about the node or nodes that have the
    specified number of commit operations.

[-total <Counter64 with Delta>] - Total Operations
    If you specify this parameter, the command displays statistics only about the node or nodes that have the
    specified number of total NFSv3 operations.

[-null-pct <Counter with Delta>] - Percent Null Ops
    If you specify this parameter, the command displays statistics only about the node or nodes that have the
    specified percentage of null operations.

[-gattr-pct <Counter with Delta>] - Percent GetAttr Ops
    If you specify this parameter, the command displays statistics only about the node or nodes that have the
    specified percentage of getattr operations.

[-sattr-pct <Counter with Delta>] - Percent SetAttr Ops
    If you specify this parameter, the command displays statistics only about the node or nodes that have the
    specified percentage of setattr operations.

[-lookup-pct <Counter with Delta>] - Percent LookUp Ops
    If you specify this parameter, the command displays statistics only about the node or nodes that have the
    specified percentage of lookup operations.

[-access-pct <Counter with Delta>] - Percent Access Ops
    If you specify this parameter, the command displays statistics only about the node or nodes that have the
    specified percentage of access operations.

[-rsym-pct <Counter with Delta>] - Percent ReadSymlink Ops
    If you specify this parameter, the command displays statistics only about the node or nodes that have the
    specified percentage of readsymlink operations.

[-read-pct <Counter with Delta>] - Percent Read Ops
    If you specify this parameter, the command displays statistics only about the node or nodes that have the
    specified percentage of read operations.

[-write-pct <Counter with Delta>] - Percent Write Ops
    If you specify this parameter, the command displays statistics only about the node or nodes that have the
    specified percentage of write operations.

[-create-pct <Counter with Delta>] - Percent Create Ops
    If you specify this parameter, the command displays statistics only about the node or nodes that have the
    specified percentage of create operations.
[-mkdir-pct <Counter with Delta>] - Percent MkDir Ops
    If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of mkdir operations.

[-symlink-pct <Counter with Delta>] - Percent SymLink Ops
    If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of symlink operations.

[-mknod-pct <Counter with Delta>] - Percent MkNod Ops
    If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of mknod operations.

[-remove-pct <Counter with Delta>] - Percent Remove Ops
    If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of remove operations.

[-rmdir-pct <Counter with Delta>] - Percent RmDir Ops
    If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of rmdir operations.

[-rename-pct <Counter with Delta>] - Percent Rename Ops
    If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of rename operations.

[-link-pct <Counter with Delta>] - Percent Link Ops
    If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of link operations.

[-rdir-pct <Counter with Delta>] - Percent ReadDir Ops
    If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of readdir operations.

[-rdirp-pct <Counter with Delta>] - Percent ReadDirPlus Ops
    If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of readdirplus operations.

[-fsstat-pct <Counter with Delta>] - Percent FsStat Ops
    If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of fsstat operations.

[-fsinfo-pct <Counter with Delta>] - Percent FsInfo Ops
    If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of fsinfo operations.

[-pconf-pct <Counter with Delta>] - Percent PathConf Ops
    If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of pathconf operations.

[-commit-pct <Counter with Delta>] - Percent Commit Ops
    If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of commit operations.

Examples

The following example displays statistics about the NFSv3 operations for a node named node1:

```
cluster1::> statistics-v1 nfs show-v3 -node node1
```

<table>

**statistics-v1 nfs show-v4**

Display NFSv4 statistics

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**
The `statistics-v1 nfs show-v4` command displays the following statistics about the NFSv4 operations on each node in the cluster:

- Result of the operations (success or failure)
- Total number of null operations
- Total number of compound operations
- Total number of access operations
- Total number of close operations
- Total number of commit operations
- Total number of create operations
- Total number of delegpurge operations
- Total number of delegret operations
- Total number of getattr operations
- Total number of getfh operations
- Total number of link operations
- Total number of lock operations
- Total number of lockt operations
- Total number of locku operations
- Total number of lookup operations
- Total number of lookupp operations
- Total number of nverify operations
- Total number of open operations
- Total number of openattr operations
- Total number of openconf operations
- Total number of opendowng operations
- Total number of putfh operations
- Total number of putpubfh operations
- Total number of putrootfh operations
- Total number of read operations
- Total number of readdir operations
- Total number of readlink operations
• Total number of remove operations
• Total number of rename operations
• Total number of renew operations
• Total number of restorefh operations
• Total number of savefh operations
• Total number of secinfo operations
• Total number of setattr operations
• Total number of setcliid operations
• Total number of setcliidconf operations
• Total number of verify operations
• Total number of write operations
• Total number of rellockown operations
• Total number of total operations
• Percent of null operations
• Percent of compound operations
• Percent of access operations
• Percent of close operations
• Percent of commit operations
• Percent of create operations
• Percent of delegpurge operations
• Percent of delegret operations
• Percent of getattr operations
• Percent of getfh operations
• Percent of link operations
• Percent of lock operations
• Percent of lockt operations
• Percent of locku operations
• Percent of lookup operations
• Percent of lookupp operations
• Percent of nverify operations
• Percent of open operations
• Percent of openattr operations
• Percent of openconf operations
• Percent of opendowng operations
This command is designed to be used to analyze performance characteristics and to help diagnose issues.

**Parameters**

```
[-fields <fieldname>, ...]
```

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

```
[-instance ]
```

If you specify the `-instance` parameter, the command displays detailed information about all fields.

```
[-node <nodename> | local ] - Node
```

If you specify this parameter, the command displays NFSv4 statistics only for the specified node.

```
[-result {success | failure | all} ] - Result
```

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified result (success/failure/all).

```
[-null <Counter with Delta>] - Null Procedure
```

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of null operations.

```
[-cmpnd <Counter with Delta>] - Compound Procedure
```

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of compound operations.
[-access <Counter with Delta>] - Access Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of access operations.

[-close <Counter with Delta>] - Close Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of close operations.

[-commit <Counter with Delta>] - Commit Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of commit operations.

[-create <Counter with Delta>] - Create Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of create operations.

[-delpur <Counter with Delta>] - Delegpurge Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of delegpurge operations.

[-delrtn <Counter with Delta>] - Delegret Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of delegret operations.

[-gattr <Counter with Delta>] - GetAttr Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of getattr operations.

[-getfh <Counter with Delta>] - GetFh Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of getfh operations.

[-link <Counter with Delta>] - Link Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of link operations.

[-lock <Counter with Delta>] - Lock Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of lock operations.

[-lockt <Counter with Delta>] - LockT Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of lockt operations.

[-locku <Counter with Delta>] - LockU Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of locku operations.

[-lookup <Counter with Delta>] - Lookup Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of lookup operations.

[-lookpp <Counter with Delta>] - LookupP Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of lookpp operations.

[-nverify <Counter with Delta>] - Nverify Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of nverify operations.
[open <Counter with Delta>] - Open Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of open operations.

[opattr <Counter with Delta>] - OpenAttr Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of openattr operations.

[opconf <Counter with Delta>] - OpenConf Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of openconf operations.

[opndg <Counter with Delta>] - OpenDowng Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of opendowng operations.

[putfh <Counter with Delta>] - PutFh Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of putfh operations.

[putpfh <Counter with Delta>] - PutPubFh Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of putpubfh operations.

[putrfh <Counter with Delta>] - PutRootFh Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of putrootfh operations.

[read <Counter with Delta>] - Read Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of read operations.

[readdr <Counter with Delta>] - ReadDir Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of readdr operations.

[rlink <Counter with Delta>] - ReadLink Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of rlink operations.

[remove <Counter with Delta>] - Remove Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of remove operations.

[rename <Counter with Delta>] - Rename Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of rename operations.

[renew <Counter with Delta>] - Renew Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of renew operations.

[restfh <Counter with Delta>] - RestoreFh Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of restfh operations.

[savefh <Counter with Delta>] - SaveFh Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of savefh operations.
-secinf <Counter with Delta> - SecInfo Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of secinfo operations.

-sattr <Counter with Delta> - SetAttr Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of setattr operations.

-sclid <Counter with Delta> - SetCliId Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of setcliid operations.

-scidc <Counter with Delta> - SetCliIdConf Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of setcliidconf operations.

-verify <Counter with Delta> - Verify Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of verify operations.

-write <Counter with Delta> - Write Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of write operations.

-relown <Counter with Delta> - RelLockOwn Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of rellockown operations.

-total <Counter64 with Delta> - Total Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of total nfsv4 operations.

-null-pct <Counter with Delta> - Percent Null Procedure
  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of null operations.

-cmpnd-pct <Counter with Delta> - Percent Compound Procedure
  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of compound operations.

-access-pct <Counter with Delta> - Percent Access Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of access operations.

-close-pct <Counter with Delta> - Percent Close Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of close operations.

-commit-pct <Counter with Delta> - Percent Commit Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of commit operations.

-create-pct <Counter with Delta> - Percent Create Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of create operations.

-delpur-pct <Counter with Delta> - Percent Delegpurge Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of delegpurge operations.
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of delegret operations.

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of getattr operations.

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of getfh operations.

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of link operations.

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of lock operations.

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of lockt operations.

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of locku operations.

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of lookup operations.

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of lookupp operations.

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of nverify operations.

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of open operations.

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of openattr operations.

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of openconf operations.

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of opendowng operations.

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of putfh operations.
[-putpfh-pct <Counter with Delta>] - Percent PutPubFh Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the
specified percentage of putpubfh operations.

[-putrfh-pct <Counter with Delta>] - Percent PutRootFh Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the
specified percentage of putrootfh operations.

[-read-pct <Counter with Delta>] - Percent Read Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the
specified percentage of read operations.

[-readdr-pct <Counter with Delta>] - Percent ReadDir Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the
specified percentage of readdir operations.

[-rlink-pct <Counter with Delta>] - Percent ReadLink Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the
specified percentage of readlink operations.

[-remove-pct <Counter with Delta>] - Percent Remove Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the
specified percentage of remove operations.

[-rename-pct <Counter with Delta>] - Percent Rename Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the
specified percentage of rename operations.

[-renew-pct <Counter with Delta>] - Percent Renew Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the
specified percentage of renew operations.

[-restfh-pct <Counter with Delta>] - Percent RestoreFh Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the
specified percentage of restorefh operations.

[-savefh-pct <Counter with Delta>] - Percent SaveFh Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the
specified percentage of savefh operations.

[-secinf-pct <Counter with Delta>] - Percent SecInfo Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the
specified percentage of secinfo operations.

[-sattr-pct <Counter with Delta>] - Percent SetAttr Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the
specified percentage of setattr operations.

[-sclid-pct <Counter with Delta>] - Percent SetCliId Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the
specified percentage of setcliid operations.

[-scidc-pct <Counter with Delta>] - Percent SetCliIdConf Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the
specified percentage of setcliidconf operations.

[-verify-pct <Counter with Delta>] - Percent Verify Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the
specified percentage of verify operations.
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of write operations.

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of rellockown operations.

**Examples**

The following example displays statistics about the NFSv4 operations for a node named node1:

```
cluster1::> statistics-v1 nfs show-v4 -node node1
```

```
Node          Value       Delta       Percent Ops  Delta
null           ---------------------------success-----------------------
null Procs:    2            -             1%                  -
Compound Procs: 92           -                  -
Access Ops:    16           -             6%                  -
Close Ops:     8            -             3%                  -
Commit Ops:    0            -             0%                  -
Create Ops:    0            -             0%                  -
Delete Ops:    0            -             0%                  -
Delete Inq:    0            -             0%                  -
Getattr Ops:   76           -             27%                 -
Gethdr Ops:    22           -             8%                  -
Link Ops:      0            -             0%                  -
Lock Op:       0            -             0%                  -
Lockc Op:      0            -             0%                  -
Locku Op:      0            -             0%                  -
Lookup Op:     13           -             5%                  -
Lockup Op:     0            -             0%                  -
Noverify Op:   0            -             0%                  -
Open Op:       8            -             3%                  -
Openattr Op:   0            -             0%                  -
Openconfig Op: 0            -             0%                  -
Openr Q:       0            -             0%                  -
Putfdr Op:     92           -             32%                 -
Putrootfdr Op: 2            -             1%                  -
Read Op:       0            -             0%                  -
Readlink Op:   2            -             1%                  -
Readlink Op:   0            -             0%                  -

**statistics-v1 protocol-request-size commands**

The protocol-request-size directory
statistics-v1 protocol-request-size show

Display size statistics for CIFS and NFS protocol read and write requests

**Availability:** This command is available to cluster administrators at the admin privilege level.

**Description**
This command displays size statistics for CIFS and NFS protocol read and write requests. The output of the command includes the following information:

- Node name
- Statistic type
- Average size of request
- Total request count
- Current number of requests in each category of request size
- Number of requests after the command was last executed

**Parameters**

```
[-fields <fieldname>, ...]
```
If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

```
[-instance]
```
If you specify the `-instance` parameter, the command displays detailed information about all fields.

```
[-node {<nodename> | local}] - Node
```
If this parameter is specified, the command displays statistics only for the specified node.

```
[-stat-type <Protocol Type>] - RW Request Stat Type
```
If this parameter is specified, the command displays only the statistics of the specified protocol type. Protocol types include the following: cifs_read, cifs_write, nfs2_read, nfs2_write, nfs3_read, and nfs3_write.

```
[-total-req-count <Counter64 with Delta>] - Total Request Count
```
If this parameter is specified, the command displays only statistics with the specified total number of requests.

```
[-average-size <Counter64 with Delta>] - Average Request Size
```
If this parameter is specified, the command displays only statistics with the specified average request size.

```
[-histo08 <Counter64 with Delta>] - 0 - 511
```
If this parameter is specified, the command displays only statistics with the specified number of requests in this size range.

```
[-histo09 <Counter64 with Delta>] - 512 - 1023
```
If this parameter is specified, the command displays only statistics with the specified number of requests in this size range.

```
[-histo10 <Counter64 with Delta>] - 1024 - 2047
```
If this parameter is specified, the command displays only statistics with the specified number of requests in this size range.

```
[-histo11 <Counter64 with Delta>] - 2048 - 4096
```
If this parameter is specified, the command displays only statistics with the specified number of requests in this size range.
If this parameter is specified, the command displays only statistics with the specified number of requests in this size range.

If this parameter is specified, the command displays only statistics with the specified number of requests in this size range.

If this parameter is specified, the command displays only statistics with the specified number of requests in this size range.

If this parameter is specified, the command displays only statistics with the specified number of requests in this size range.

If this parameter is specified, the command displays only statistics with the specified number of requests in this size range.

If this parameter is specified, the command displays only statistics with the specified number of requests in this size range.

If this parameter is specified, the command displays only statistics with the specified number of requests in this size range.

If this parameter is specified, the command displays only statistics with the specified number of requests in this size range.

Examples

The following example displays the number of NFS v3 requests in each size range for only one node in the cluster.

cluster1::> statistics protocol-request-size show -stat-type nfs3_* -node node0

<table>

Statistics Commands

The statistics directory
The statistics commands display performance statistics.

statistics show
Display performance data for a time interval

Availability: This command is available to cluster and Vserver administrators at the advanced privilege level.

Description
This command displays performance data for a period of time.
To display data for a period of time, collect a sample using the statistics start and statistics stop commands. The data that displays is calculated data based on the samples the cluster collects. To view the sample, specify the -sample-id parameter.

Parameters

{-fields <fieldname>, ...}
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use `-fields ?' to display the fields to specify.

| [-tab ]
If this parameter is specified, the command displays performance data in tabular format.

{-object <text>} - Object
Selects the objects for which you want to display performance data. To view a list of valid object names, type statistics show -object ? or statistics catalog object show. To specify multiple objects, use "|" between each object.

Caution: You should limit the scope of this command to only a few objects at a time to avoid a potentially significant impact on the performance of the system.

{-instance <text>} - Instance
Selects the instances for which you want to display performance data. If you do not specify this parameter, the command displays statistics for all of the instances associated with the specified objects. To specify multiple instances, use "|" between each instance.
For example, if you want to display disk object statistics, you can use this parameter to specify the name of a specific disk whose statistics you want to view. If you do not specify this parameter, the command displays statistics for all disks in the system.

{-counter <text>} - Counter
Selects the counters for which you want to display performance data. To specify multiple counters, use "|" between each counter.

{-preset <text>} - Preset
If this parameter is specified, the command displays statistics for the specified preset.

{-node (<nodename> | local)} - Node
Selects the nodes for which you want to display performance data.
[-vserver <vserver name>] - Vserver
   Selects the Vserver for which you want to display performance data.

[-value <text>] - Text Value
   Selects the performance data that matches the specified counter value.

[-labels <text>, ...] - List of Labels
   Selects the performance data that matches the specified label.

[-values <text>, ...] - List of Values
   Displays only the statistics that have the specified values.

[-filter <text>] - Filter Data
   Selects performance data for the instance that matches the specified filter criteria. For example, to display the instances that match a value of greater than 50 for the total_ops counter, specify -filter "total_ops>50".

[-sample-id <text>] - Sample Identifier
   Displays performance data for the specified sample. You collect a sample by using the statistics start and statistics stop commands.

[-interval <integer>] - Interval
   Specifies, in seconds, the interval between statistics updates. The default setting is 5 seconds.

[-iterations <integer>] - Iterations
   Specifies the number of iterations the command runs before terminating. The default setting is 1. If the number is 0 (zero), the command continues to run until you interrupt it by pressing Ctrl-C.

[-sort-key <text>] - Counter Used For Sorting
   If this parameter is specified, the command displays statistics sorted by the specified counter. Only one counter can be specified.

[-sort-order {ascending|descending}] - Sort Order
   This parameter may be used in conjunction with the -sort-key parameter. This parameter changes the order in which statistics are sorted. Possible values are ascending and descending. The default setting is descending.

[-max <integer>] - Tracker Size
   Specifies the number of most active instances of an active object to display. The default setting is to display all of the instances.

Examples
The following example starts collecting statistics and displays statistics for the sample named smpl_1 for counters: avg_processor_busy and cpu_busy

```
cluster1::*> statistics start -object system -counter avg_processor_busy|cpu_busy -sample-id smpl_1
Statistics collection is being started for Sample-id: smpl_1
cluster1::*> statistics show -sample-id smpl_1
Object: system
Instance: cluster
Start-time: 8/2/2012 18:27:53
End-time: 8/2/2012 18:27:56
Cluster: cluster1
Counter             Value
--------------------- ---------------------
avg_processor_busy  6%
cpu_busy            6%
```

The following example starts and stops data collection and displays statistics for the sample named smpl_1 for counters: avg_processor_busy and cpu_busy
cluster1::*> statistics start -object system -counter avg_processor_busy|cpu_busy -sample-id smpl_1
Statistics collection is being started for Sample-id: smpl_1

cluster1::*> statistics stop -sample-id smpl_1
Statistics collection is being stopped for Sample-id: smpl_1

cluster1::*> statistics show -sample-id smpl_1
Object: system
Instance: cluster
Start-time: 8/2/2012 18:27:53
End-time: 8/2/2012 18:27:56
Cluster: cluster1
Counter                                                      Value
-------------------------------- --------------------------------
avg_processor_busy                                             6%
cpu_busy                                                       6%

The following example displays raw statistics:

cluster1::*> statistics show -raw -object system
Object: system
Instance: cluster
Start-time: 9/13/2012 18:18:18
End-time: 9/13/2012 18:18:18
Cluster: cluster1

Continuously display current performance data at regular interval

Availability: This command is available to cluster and Vserver administrators at the advanced privilege level.

Description
This command continuously displays specified performance data at a regular interval. The command output displays data in the following columns:

Note: This command has been deprecated and may be removed from a future version of Data ONTAP. Use the "statistics show" command with the tabular format instead.

- cpu avg: Average processor utilization across all processors in the system.
- cpu busy: Overall system utilization based on CPU utilization and subsystem utilization. Examples of subsystems include the storage subsystem and RAID subsystem.
- total ops: Number of total operations per second.
- nfs-ops: Number of NFS operations per second.
- cifs-ops: Number of CIFS operations per second.
- fcache ops: Number of 7M flexcache operations per second.
- pkts recv: Number of packets received over physical ports per second.
- pkts sent: Number of packets sent over physical ports per second.
- total recv: Total network traffic received over physical ports per second (KBps).
- total sent: Total network traffic sent over physical ports per second (KBps).
- data busy: The percentage of time that data ports sent or received data.
- data recv: Network traffic received on data ports (KBps).
- data sent: Network traffic sent on data ports (KBps).
- cluster busy: The percentage of time that cluster ports sent or received data.
- cluster recv: Network traffic received on cluster ports (KBps).
- cluster sent: Network traffic sent on cluster ports (KBps).
- disk read: Data read from disk (KBps).
- disk write: Data written to disk (KBps).

Parameters

[-object <text>] - Object
Selects the object for which you want to display performance data. The default object is "cluster".

[-instance <text>] - Instance
Selects the instance for which you want to display performance data. This parameter is required if you specify the -object parameter and enter any object other than "cluster". Multiple values for this parameter are not supported.
For example, if you want to display disk object statistics, you can use this parameter to specify the name of a specific disk whose statistics you want to view.

```bash
[-counter <text>] - Counter
Selects the counters for which you want to display performance data. If you do not specify this parameter, the command displays statistics for all of the counters in the specified objects. To specify multiple counters, use "|" between each counter.
```

```bash
[-preset <text>] - Preset
If this parameter is specified, the command displays statistics for the specified preset.
```

```bash
[-node {<nodename>|local]} - Node
Selects the nodes for which you want to display performance data. The default node is "cluster:summary".
```

```bash
[-vserver <vserver name>] - Vserver
Selects the Vserver for which you want to display performance data. If you do not specify this parameter, the command displays statistics for all of the Vservers in the cluster.
```

```bash
[-interval <integer>] - Interval in Seconds
Specifies, in seconds, the interval between statistics updates. The default setting is 1 second.
```

```bash
[-iterations <integer>] - Number of Iterations
Specifies the number of iterations the command runs before terminating. The default setting is 0 (zero); this means that the command continues to run until you interrupt it by pressing Ctrl-C.
```

```bash
[-summary {true|false}] - Print Summary
Specifies whether the command prints a final summary of statistics after the command has gone through all of its iterations. The default setting is true.
```

```bash
[-filter <text>] - Filter Data
Selects instances that match the specified filter criteria. For example, to display instances from node1, specify -filter "node_name=node1".
```

### Examples

The following example displays the "cluster" statistics for a node named node1. Because no number of iterations is specified, this command will continue to run until you interrupt it by pressing Ctrl-C.

```
cluster1::*> statistics show-periodic -node node1
```

## statistics start

Start data collection for a sample

**Availability:** This command is available to cluster and Vserver administrators at the advanced privilege level.

**Description**

This command starts the collection of performance data. Use the `statistics stop` command to stop the collection. You view the sample of performance data by using the `statistics show` command. You can collect more than one sample at a time.

**Parameters**

[-object <text>] - Object

Selects the objects for which you want to collect performance data. This parameter is required. To view a list of valid object names, type `statistics catalog object show` at the command prompt. To specify multiple objects, use "|" between each object.

**Caution:** You should limit the scope of this command to only a few objects at a time to avoid a potentially significant impact on the performance of the system.

[-instance <text>] - Instance

Selects the instances for which you want to collect performance data. If you do not specify this parameter, the command collects statistics for all of the instances associated with the specified objects. To specify multiple instances, use "|" between each instance.

For example, if you want to collect disk object statistics, you can use this parameter to specify the name of a specific disk whose statistics you want to view. If you do not specify this parameter, the command will collect statistics for all disks in the system.
[-counter <text>] - Counter
Selects the counters for which you want to collect performance data. If you do not specify this parameter, the command collects statistics for all of the counters in the specified objects. To specify multiple counters, use "|" between each counter.

[-preset <text>] - Preset
If this parameter is specified, the command displays statistics for the specified preset.

[-sample-id <text>] - Sample Identifier
Specifies an identifier for the sample. Identifiers must be unique and are restricted to the characters 0-9, a-z, A-Z, and ".". If you do not specify this parameter, the command generates a sample identifier for you and defines this sample as the default sample for the CLI session. When you run the statistics show command without specifying the -sample-id parameter, data from the default sample displays. If you run this command during the same CLI session and do not specify the -sample-id parameter, the command overwrites the previous sample. The command does not delete the default sample when you close your session.

[-vserver <vserver name>] - Vserver
Selects the vserver for which you want to collect performance data. If you do not specify this parameter, the command collects statistics for all of the Vservers in the cluster.

[-node {<nodename> | local}] - Node
Selects the node for which you want to collect performance data. If you do not specify this parameter, the command collects statistics for all of the nodes in the cluster.

[-filter <text>] - Filter
Selects performance data for the instance that matches the specified filter criteria. For example, to display the instances from node1, specify -filter "node_name=node1".

[-duration <integer>] - Sample Duration in Minutes
If this parameter is specified, the command will collect the closing sample after the time specified. Duration can be specified in minutes.

[-max <integer>] - Tracker Size
Specifies the number of most active instances of an active object to display. The default setting is to display all of the instances.

[-sort-key <text>] - Counter Used For Sorting
If this parameter is specified, the command displays statistics sorted by the specified counter. Only one counter can be specified.

[-sort-order {ascending|descending}] - Sort Order
This parameter may be used in conjunction with the -sort-key parameter. This parameter changes the order in which statistics are sorted. Possible values are ascending and descending. The default setting is descending.

Examples
The following example starts statistics collection for sample "smpl_1":

```
cluster1::* > statistics start -object system -sample-id smpl_1
Statistics collection is being started for Sample-id: smpl_1
```

The following example starts collecting statistics for the sample named smpl_1 for counters: avg_processor_busy and cpu_busy

```
cluster1::* > statistics start -object system -counter avg_processor_busy|cpu_busy -sample-id smpl_1
Statistics collection is being started for Sample-id: smpl_1
```
stop data collection for a sample

Availability: This command is available to cluster and Vserver administrators at the advanced privilege level.

Description
This command stops the collection of performance data. You view the sample of performance data by using the statistics show command.

Parameters

[-sample-id <text>] - Sample Identifier
Specifies the identifier of the sample for which you want to stop data collection. If you do not specify this parameter, the command stops data collection for the last sample that you started by running the statistics start command without the -sample-id parameter.

Examples
The following example stops data collection for sample "smpl_1":

```
cluster1:*> statistics stop -sample-id smpl_1
Statistics collection is being stopped for Sample-id: smpl_1
```

statistics aggregate commands

Aggregate throughput and latency metrics

statistics aggregate show

Aggregate throughput and latency metrics

Availability: This command is available to cluster administrators at the admin privilege level.

Description
This command continuously displays performance data for aggregates at a regular interval. The command output displays data in the following columns:

- Aggregate - aggregate name.
- Node - node name.
- Total Ops - total number of operations per second.
- Read Ops - read operations per second.
- Write Ops - write operations per second.

Parameters

[<aggregate <text>]] - Aggregate
Selects the aggregate for which you want to display performance data.

[<node <text> | local>] - Node
Selects the node for which you want to display performance data.

[<sort-key <text>]] - Column to Sort By
If this parameter is specified, the command displays statistics sorted by the specified column.

-<interval <integer> - Interval
Specifies, in seconds, the interval between statistics updates. The default setting is 5 seconds.

-<iterations <integer> - Iterations
Specifies the number of iterations the command runs before terminating. The default setting is 1. If the number
is 0 (zero), the command continues to run until you interrupt it by pressing Ctrl-C.

-<max <integer> - Maximum Number of Instances
Specifies maximum number of aggregates to display. The default setting is 25.

Examples

The following example displays aggregate statistics:

```
cluster1::> statistics aggregate show
cluster-1 : 12/31/1969 16:00:04

*Total Read Write
Aggregate Node Ops Ops Ops
--------------------- ------------- ------ ---- ----
aggr0_cluster_node3 aggr0_cluster_node3 0 0 0
aggr0_cluster_node4 aggr0_cluster_node4 0 0 0
```

statistics cache commands

Displays performance data for caches

statistics cache flash-pool commands

Flash pool throughput metrics

statistics cache flash-pool show

Flash pool throughput metrics

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description

This command continuously displays performance data for flash pool caches at a regular interval. The command output displays
data in the following columns:

- Aggregate - aggregate name.
• Vserver - vserver name.
• Volume - volume name.
• Read Hit - percent of IOs serviced from a cache level.
• Write Hit - percent of IOs serviced from a cache level.
• Cache Used - percent of cache used.
• Read Blocks - read blocks.
• Write Blocks - write blocks.
• Rejects - cache rejects.

Parameters

[-aggregate <text>] - Aggregate
  Selects the aggregate for which you want to display performance data.

[-vserver <vserver name>] - Vserver
  Selects the vserver for which you want to display performance data.

[-volume <text>] - Volume
  Selects the volume for which you want to display performance data.

[-sort-key <text>] - Column to Sort By
  If this parameter is specified, the command displays statistics sorted by the specified column.

interval <integer> - Interval
  Specifies, in seconds, the interval between statistics updates. The default setting is 5 seconds.

iterations <integer> - Iterations
  Specifies the number of iterations the command runs before terminating. The default setting is 1. If the number is 0 (zero), the command continues to run until you interrupt it by pressing Ctrl-C.

max <integer> - Maximum Number of Instances
  Specifies the maximum number of flash pools to display. The default setting is 25.

Examples

The following example displays flash pool statistics:

```
cluster1::> statistics cache flash-pool show
cluster1 : 12/31/2013 16:00:04

<table>
<thead>
<tr>
<th>Aggregate</th>

```

statistics catalog directory

The catalog directory

The statistics catalog commands provide access to performance catalog data.
**statistics catalog counter commands**

The counter directory

**statistics catalog counter show**

Display the list of counters in an object

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *advanced* privilege level.

**Description**

This command displays the names and descriptions of counters. The displayed data is either node-specific or cluster-wide, depending on the objects specified.

**Parameters**

```
[-fields <fieldname>, ...]
```

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `'-fields ?'` to display the fields to specify.

```
[-describe ]
```

Displays detailed information about each counter, including privilege level, label, and whether the counter is a key counter.

```
-object <text> - Object
```

Selects the object for which you want to display the list of counters. This parameter is required. To view a list of valid object names, type `statistics catalog counter show -object ?` or `statistics catalog object show`.

```
[-counter <text>] - Counter
```

Selects the counters that match this parameter value. If you do not specify this parameter, the command displays details for all counters.

```
[-filter <text>] - Filter Data
```

Selects the counters that match this parameter value. For example, to display counters from node1, specify `-filter "node_name=node1"`.

```
[-label <text>, ...] - Labels for Array Counters
```

Selects the counters that match this parameter value. A label is the name of the bucket to which an array counter belongs.

```
[-description <text>] - Description
```

Selects the counters that match this parameter value.

```
[-privilege <text>] - Privilege Level
```

Selects the counters that match this parameter value.

```
[-is-key-counter {true|false}] - Is Key Counter
```

Selects the counters that are key counters (true) or are not key counters (false). A key counter is a counter that uniquely identifies an instance across the cluster. The default setting is false. For example, "vserver_name" and "node_name" are key counters because they identify the specific Vserver or node to which the instance belongs.

```
[-is-deprecated {true|false}] - Is Counter Deprecated
```

Selects the counters that are deprecated (true) or are not deprecated (false).

```
[-replaced-by <text>] - Replaced By Counter If Deprecated
```

Selects all deprecated counters that are replaced by the counter provided to this parameter.
Examples

The following example displays the list of counters in the processor object.

```
cluster1::> statistics catalog counter show -object processor
Object: processor
<table>
<thead>
<tr>
<th>Counter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>instance_name</td>
<td>Instance Name</td>
</tr>
<tr>
<td>instance_uuid</td>
<td>Instance UUID</td>
</tr>
<tr>
<td>node_name</td>
<td>System node name</td>
</tr>
<tr>
<td>node_uuid</td>
<td>System node id</td>
</tr>
<tr>
<td>process_name</td>
<td>Ontap process that provided this instance</td>
</tr>
<tr>
<td>processor_busy</td>
<td>Percentage of elapsed time that the processor is executing non-idle processes</td>
</tr>
<tr>
<td>processor_elapsed_time</td>
<td>Wall-clock time since boot used for calculating processor utilization</td>
</tr>
<tr>
<td>sk_switches</td>
<td>Number of sk switches per second</td>
</tr>
</tbody>
</table>
8 entries were displayed.
```

statistics catalog instance commands

The instance directory

statistics catalog instance show

Display the list of instances associated with an object

Availability: This command is available to cluster and Vserver administrators at the advanced privilege level.

Description

This command displays the names of instances associated with the specified object. The displayed data is either node-specific or cluster-wide, depending on the objects specified.

Parameters

[-fields <fieldname>, ...]

If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use -fields '?' to display the fields to specify.

-object <text> - Object

Selects the object for which you want to display the list of instances. This parameter is required. To view a list of valid object names, type statistics catalog instance show -object ? or statistics catalog object show.

-<instance <text>> - Instance Name

Selects the instances that match this parameter value. If you do not specify this parameter, the command displays all the instances.

-<filter <text>> - Filter Data

Selects the instances that match this parameter value. For example, to display instances from vserver1, specify -filter "vserver_name=vserver1".

-<vserver <vserver name>, ...> - Vserver Name

Selects the instances that match this parameter value. If you do not specify this parameter, the command displays instances for all of the Vservers in the cluster.
[node {<nodename>|local}, ...] - Node Name

Selects the instances that match this parameter value. If you do not specify this parameter, the command displays instances for all of the nodes in the cluster.

Examples

The following example displays the list of instances associated with the processor object.

```
cluster1::> statistics catalog instance show -object processor
Object: processor
processor0
processor0
processor1
processor1
4 entries were displayed.
```

**statistics catalog object commands**

The object directory

**statistics catalog object show**

Display the list of objects

*Availability:* This command is available to cluster and Vserver administrators at the advanced privilege level.

*Description*

This command displays the names and descriptions of objects from which you can obtain performance data. The displayed data is either node-specific or cluster-wide, depending on the objects specified.

*Parameters*

```
{ [-fields <fieldname>, ...] 
  If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

| [-describe] 
  Displays detailed information about each object, including privilege level.

| [-object <text>] - Object 
  Selects the objects for which you want to display information. If you do not specify this parameter, the command displays details for all of the objects.

| [-privilege <text>] - Privilege Level 
  Selects the objects that match this parameter value.

| [-is-deprecated {true|false}] - Is Object Deprecated 
  Selects the objects that are deprecated (true) or are not deprecated (false).

| [-replaced-by <text>] - Replaced By Object If Deprecated 
  Selects all deprecated objects that are replaced by the object provided to this parameter.

| [-is-statistically-tracked {true|false}] - Is Object Statistically Tracked 
  Specifies if the object is statistically tracked
```
[-description <text>] - Description

Selects the objects that match this parameter value.

**Examples**

The following example displays descriptions of all objects in the cluster:

```bash
cluster1::> statistics catalog object show
aggregate                   CM object for exporting aggregate performance counters
audit_ng                    CM object for exporting audit_ng performance counters
cifs                        These counters report activity from both SMB and SMB2 revisions of the CIFS protocol. For information isolated to SMB, see the 'smb1' object. For SMB2, see the 'smb2' object.
cifs:node                   These counters report activity from both SMB and SMB2 revisions of the CIFS protocol. For information isolated to SMB, see the 'smb1' object. For SMB2, see the 'smb2' object.
cifs:vserver                These counters report activity from both SMB and SMB2 revisions of the CIFS protocol. For information isolated to SMB, see the 'smb1' object. For SMB2, see the 'smb2' object.
cluster_peer                The cluster peer object contains peer counters.

### statistics disk commands

Disk throughput and latency metrics

### statistics disk show

Disk throughput and latency metrics

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

**Description**

This command continuously displays performance data for disks at a regular interval. The command output displays data in the following columns:

- Disk - disk name.
- Node - node name.
- Busy (%) - percentage of time there was at least one outstanding request to the disk.
- Total Ops - total operations per second.
- Read Ops - read operations per second.
- Write Ops - write operations per second.

**Parameters**

[-disk <text>] - Disk

Selects the disk for which you want to display performance data.

[-node {<nodename> | local}] - Node

Selects the node for which you want to display performance data.
[-sort-key <text>] - Column to Sort By

If this parameter is specified, the command displays statistics sorted by the specified column.

-interval <integer> - Interval

Specifies, in seconds, the interval between statistics updates. The default setting is 5 seconds.

-iterations <integer> - Iterations

Specifies the number of iterations the command runs before terminating. The default setting is 1. If the number is 0 (zero), the command continues to run until you interrupt it by pressing Ctrl-C.

-max <integer> - Maximum Number of Instances

Specifies the maximum number of disks to display. The default setting is 25.

Examples
The following example displays disk statistics:

```
cluster1::> statistics disk show
cluster1 : 12/31/1969 16:00:04
Busy *Total Read Write
Disk          Node (%) Ops  Ops  Ops
-------- -------- ---- ------ ---- -----
VMw-1.31     node2    0      2    2     0
VMw-1.30     node2    0      3    0     3
VMw-1.3      node1    0      0    0     0
VMw-1.29     node2    0      1    0     1
[...]```
Parameters

- **[-lif <text>] - LIF**
  Selects the LIF for which you want to display performance data.

- **[-vserver <vserver name>] - Vserver**
  Selects the vserver for which you want to display performance data.

- **[-sort-key <text>] - Column to Sort By**
  If this parameter is specified, the command displays statistics sorted by the specified column.

- **[-interval <integer>] - Interval**
  Specifies, in seconds, the interval between statistics updates. The default setting is 5 seconds.

- **[-iterations <integer>] - Iterations**
  Specifies the number of iterations the command runs before terminating. The default setting is 1. If the number is 0 (zero), the command continues to run until you interrupt it by pressing Ctrl-C.

- **[-max <integer>] - Maximum Number of Instances**
  Specifies the maximum number of LIFs to display. The default setting is 25.

Examples

The following example displays LIFs statistics:

```
cluster1::> statistics lif show
cluster1 : 12/31/1969 16:00:04

<table>

LUN throughput and latency metrics

**Availability:** This command is available to cluster and Vserver administrators at the admin privilege level.

**Description**

This command continuously displays performance data for LUNs at a regular interval. The command output displays data in the following columns:

- Lun - LUN name.
- Vserver - vserver name.
- Total Ops - total number of operations per second.
- Read Ops - read operations per second.
• Write Ops - write operations per second.
• Other Ops - other operations per second.
• Read (Bps) - read throughput in bytes per second.
• Write (Bps) - write throughput in bytes per second.
• Latency(ms) - average latency for an operation in milliseconds.

**Parameters**

- **[-vserver <vserver name>] - Vserver**
  Selects the vserver for which you want to display performance data.

- **[-sort-key <text>] - Column to Sort By**
  If this parameter is specified, the command displays statistics sorted by the specified column.

- **[-interval <integer>] - Interval**
  Specifies, in seconds, the interval between statistics updates. The default setting is 5 seconds.

- **[-iterations <integer>] - Iterations**
  Specifies the number of iterations the command runs before terminating. The default setting is 1. If the number is 0 (zero), the command continues to run until you interrupt it by pressing Ctrl-C.

- **[-max <integer>] - Maximum Number of Instances**
  Specifies the maximum number of LUNs to display. The default setting is 25.

**Examples**

The following example displays LUN statistics:

```
cluster1::> statistics lun show
cluster1 : 12/31/2013 16:00:04

<table>
<thead>
<tr>
<th>Lun</th>
<th>Vserver</th>
<th>Total Read</th>
<th>Write</th>
<th>Other</th>
<th>Read (Bps)</th>
<th>Write (Bps)</th>
<th>Latency (ms)</th>
</tr>
</thead>
<tbody>
<tr>
<td>lun1</td>
<td>vs1</td>
<td>58</td>
<td>13</td>
<td>15</td>
<td>29</td>
<td>310585</td>
<td>39</td>
</tr>
<tr>
<td>lun0</td>
<td>vs2</td>
<td>56</td>
<td>0</td>
<td>11</td>
<td>45</td>
<td>8192</td>
<td>47</td>
</tr>
</tbody>
</table>
```

**statistics namespace commands**

Namespace throughput and latency metrics

**statistics namespace show**

Namespace throughput and latency metrics

**Availability:** This command is available to cluster and Vserver administrators at the admin privilege level.

**Description**

This command continuously displays performance data for Namespaces at a regular interval. The command output displays data in the following columns:

• Namespace - Namespace name.
- Vserver - vserver name.
- Total Ops - total number of operations per second.
- Read Ops - read operations per second.
- Write Ops - write operations per second.
- Other Ops - other operations per second.
- Read (Bps) - read throughput in bytes per second.
- Write (Bps) - write throughput in bytes per second.
- Latency(ms) - average latency for an operation in milliseconds.

Parameters

[-namespace <text>] - Namespace
Selects the Namespace for which you want to display performance data.

[-vserver <vserver name>] - Vserver
Selects the vserver for which you want to display performance data.

[-sort-key <text>] - Column to Sort By
If this parameter is specified, the command displays statistics sorted by the specified column.

-interval <integer> - Interval
Specifies, in seconds, the interval between statistics updates. The default setting is 5 seconds.

-iterations <integer> - Iterations
Specifies the number of iterations the command runs before terminating. The default setting is 1. If the number
is 0 (zero), the command continues to run until you interrupt it by pressing Ctrl-C.

-max <integer> - Maximum Number of Instances
Specifies the maximum number of Namespaces to display. The default setting is 25.

Examples

The following example displays Namespace statistics:

```
cluster1::> statistics namespace show
cluster1 : 12/31/2017 16:00:04

<table>
<thead>
<tr>
<th>Namespace</th>
<th>Vserver</th>
<th>Total Read</th>
<th>Write</th>
<th>Other</th>
<th>Read (Bps)</th>
<th>Write (Bps)</th>
<th>Latency (ms)</th>
</tr>
</thead>
<tbody>
<tr>
<td>ns1</td>
<td>vs1</td>
<td>58</td>
<td>13</td>
<td>15</td>
<td>29</td>
<td>310585</td>
<td>3014</td>
</tr>
<tr>
<td>ns0</td>
<td>vs2</td>
<td>56</td>
<td>0</td>
<td>11</td>
<td>45</td>
<td>8192</td>
<td>28826</td>
</tr>
</tbody>
</table>

[...]
```

**statistics nfs commands**

Monitor NFS statistics
statistics nfs show-mount

Display mount statistics

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
The statistics nfs show-mount command displays the following statistics about the NFS mounts on each node in the cluster:

- Result of the operations (success or failure)
- Total number of null operations
- Total number of mount operations
- Total number of dump operations
- Total number of unmount operations
- Total number of unmountall operations
- Total number of export operations
- Total number of exportall operations
- Total number of pathconf operations
- Total number of all the above operations

This command is designed to be used to analyze performance characteristics and to help diagnose issues.

Parameters

{ [-fields <fieldname>, ...]  
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use ‘-fields?’ to display the fields to specify.

| [-instance]  
If you specify the -instance parameter, the command displays detailed information about all fields.

[-node <nodename>|local] - Node
If you specify this parameter, the command displays statistics only for the specified node.

[-result (success|failure|all)] - Result
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified result (success/failure/all).

[-null <Counter with Delta>] - Null Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of null operations.

[-mount <Counter with Delta>] - Mount Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of mount operations.

[-dump <Counter with Delta>] - Dump Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of dump operations.
[-unmnt <Counter with Delta>] - UnMount Operations

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of unmount operations.

[-unmntall <Counter with Delta>] - UnMountAll Operations

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of unmountall operations.

[-export <Counter with Delta>] - Export Operations

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of export operations.

[-exportall <Counter with Delta>] - ExportAll Operations

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of exportall operations.

[-pathconf <Counter with Delta>] - PathConf Operations

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of pathconf operations.

[-total <Counter64 with Delta>] - Total Operations

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of total operations.

Examples

The following example displays statistics about the NFS mounts for a node named node1:

```
cluster1::*> statistics nfs show-mount -node node1

Node                     Value         Delta
node1               ----------success-------
Null Ops:                    2       0/s:16s
Mount Ops:                   1       0/s:16s
Dump Ops:                    0             -
Unmount Ops:                 1       0/s:16s
Unmount All Ops:             0             -
Export Ops:                  0             -
ExportAll Ops:               0             -
PathConf Ops:                0             -
Total Ops:                   4       0/s:16s

Node                     Value         Delta
node1               ----------failure-------
Null Ops:                    0             -
Mount Ops:                   0             -
Dump Ops:                    0             -
Unmount Ops:                 0             -
Unmount All Ops:             0             -
Export Ops:                  0             -
ExportAll Ops:               0             -
PathConf Ops:                0             -
Total Ops:                   0             -
```

```
statistics nfs show-nlm

(DEPRECATED)-Display NLM statistics

Availability: This command is available to cluster administrators at the advanced privilege level.

Description

The statistics nfs show-nlm command displays the following statistics about the Network Lock Manager (NLM) on each node in the cluster:
• Result of the operations (success or failure)
• Total number of null operations
• Total number of test operations
• Total number of lock operations
• Total number of cancel operations
• Total number of unlock operations
• Total number of granted operations
• Total number of share operations
• Total number of unshare operations
• Total number of nmlock operations
• Total number of freeall operations
• Total number of all the above operations

This command is designed to be used to analyze performance characteristics and to help diagnose issues.

**Note:** This command requires an effective cluster version earlier than Data ONTAP 9.0. Data for nodes running Data ONTAP 9.0 or later is not collected, and will not be displayed. Use the `statistics show-object nlm` command instead.

**Parameters**

```
[[-fields <fieldname>, ...]
  If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified
  field or fields. You can use `-fields ?` to display the fields to specify.

| [-instance ]
  If you specify the -instance parameter, the command displays detailed information about all fields.

[-node {<nodename>|local}] - Node
  If you specify this parameter, the command displays statistics only for the specified node.

[-result {success|failure|all}] - Result
  If you specify this parameter, the command displays statistics only about the node or nodes that have the
  specified result (success/failure/all).

[-null <Counter with Delta>] - Null Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the
  specified number of null operations.

[-test <Counter with Delta>] - Test Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the
  specified number of test operations.

[-lock <Counter with Delta>] - Lock Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the
  specified number of lock operations.

[-cancel <Counter with Delta>] - Cancel Operations
  If you specify this parameter, the command displays statistics only about the node or nodes that have the
  specified number of cancel operations.
```

statistics nfs commands
[−unlock \(<\text{Counter with Delta}>\)] - Unlock Operations
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of unlock operations.

[−granted \(<\text{Counter with Delta}>\)] - Granted Operations
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of granted operations.

[−share \(<\text{Counter with Delta}>\)] - Share Operations
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of share operations.

[−unshare \(<\text{Counter with Delta}>\)] - Unshare Operations
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of unshare operations.

[−nmlock \(<\text{Counter with Delta}>\)] - NmLock Operations
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of nmlock operations.

[−freeall \(<\text{Counter with Delta}>\)] - FreeAll Operations
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of freeall operations.

[−total \(<\text{Counter64 with Delta}>\)] - Total Operations
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of total operations.

### Examples
The following example displays statistics about the NLM for a node named node1:

```
ccluster1::*> statistics nfs show-nlm -node node1

Node                 Value         Delta
node1             --------success-------
Null:                    0             -
Test:                    0             -
Lock:                    2       0/s:23s
Cancel:                  0             -
Unlock:                  1       0/s:23s
Granted:                 0             -
Share:                   0             -
Unshare:                 0             -
NmLock:                  0             -
FreeAll:                 0             -
Total:                   3       0/s:23s

Node                 Value         Delta
node1             --------failure-------
Null:                    0             -
Test:                    0             -
Lock:                    0             -
Cancel:                  0             -
Unlock:                  0             -
Granted:                 0             -
Share:                   0             -
Unshare:                 0             -
NmLock:                  0             -
FreeAll:                 0             -
Total:                   0             -
```
statistics nfs show-statusmon

Display status monitor statistics

Availability: This command is available to cluster administrators at the advanced privilege level.

Description
The statistics nfs show-statusmon command displays the following statistics about the Status Monitor on each node in the cluster:

- Result of the operations (success or failure)
- Total number of null operations
- Total number of stat operations
- Total number of monitor operations
- Total number of unmonitor operations
- Total number of unmonitor all operations
- Total number of simucrash operations
- Total number of notify operations
- Total number of all the above operations

This command is designed to be used to analyze performance characteristics and to help diagnose issues.

Parameters

{ [-fields <fieldname>, ...]  
If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use `-fields ?' to display the fields to specify.

| [-instance ]]  
If you specify the -instance parameter, the command displays detailed information about all fields.

[-node {<nodename>|local}] - Node
If you specify this parameter, the command displays statistics only for the specified node.

[-result {success|failure|all}] - Result
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified result (success/failure/all).

[-null <Counter with Delta>] - Null Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of null operations.

[-stat <Counter with Delta>] - Stat Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of stat operations.

[-monitor <Counter with Delta>] - Monitor Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of monitor operations.
[-unmonitor <Counter with Delta>] - Unmonitor Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of unmonitor operations.

[-unmonall <Counter with Delta>] - Unmonitor All Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of unmonitor all operations.

[-simucrash <Counter with Delta>] - SimuCrash Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of simucrash operations.

[-notify <Counter with Delta>] - Notify Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of notify operations.

[-total <Counter64 with Delta>] - Total Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of total operations.

Examples
The following example displays statistics about the status monitor for a node named node1:

```
cluster1::*> statistics nfs show-statusmon -node node1

Node                   Value         Delta
node1               --------success-------
Null Ops:                  0             -
Stat Ops:                  0             -
Monitor Ops:               0             -
Unmonitor Ops:             0             -
Unmon All Ops:             0             -
SimuCrash Ops:             0             -
Notify Ops:                0             -
Total Ops:                 0             -

Node                   Value         Delta
node1               --------failure-------
Null Ops:                  0             -
Stat Ops:                  0             -
Monitor Ops:               0             -
Unmonitor Ops:             0             -
Unmon All Ops:             0             -
SimuCrash Ops:             0             -
Notify Ops:                0             -
Total Ops:                 0             -
```

statistics nfs show-v3
Display NFSv3 statistics

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The statistics nfs show-v3 command displays the following statistics about the NFSv3 operations on each node in the cluster:

- Result of the operations (success or failure)
- Total number of null operations
- Total number of setattr operations
• Total number of setattr operations
• Total number of lookup operations
• Total number of access operations
• Total number of readsymlink operations
• Total number of read operations
• Total number of write operations
• Total number of create operations
• Total number of mkdir operations
• Total number of symlink operations
• Total number of mknod operations
• Total number of remove operations
• Total number of rmdir operations
• Total number of rename operations
• Total number of link operations
• Total number of readdir operations
• Total number of readdirplus operations
• Total number of fsstat operations
• Total number of fsinfo operations
• Total number of pathconf operations
• Total number of commit operations
• Total number of nfsv3 operations
• Percent of null operations
• Percent of getattr operations
• Percent of setattr operations
• Percent of lookup operations
• Percent of access operations
• Percent of readsymlink operations
• Percent of read operations
• Percent of write operations
• Percent of create operations
• Percent of mkdir operations
• Percent of symlink operations
• Percent of mknod operations
• Percent of remove operations
- Percent of rmdir operations
- Percent of rename operations
- Percent of link operations
- Percent of readdir operations
- Percent of readdirplus operations
- Percent of fsstat operations
- Percent of fsinfo operations
- Percent of pathconf operations
- Percent of commit operations

This command is designed to be used to analyze performance characteristics and to help diagnose issues.

**Parameters**

`[-fields <fieldname>, ...]`  
If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

`[-instance]`  
If you specify the `-instance` parameter, the command displays detailed information about all fields.

`[-node {<nodename> | local}] - Node`  
If you specify this parameter, the command displays NFSv3 statistics only for the specified node.

`[-result {success | failure | all}] - Result`  
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified result (success/failure/all).

`[-null <Counter with Delta>] - Null Operations`  
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of null operations.

`[-getattr <Counter with Delta>] - GetAttr Operations`  
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of getattr operations.

`[-setattr <Counter with Delta>] - SetAttr Operations`  
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of setattr operations.

`[-lookup <Counter with Delta>] - LookUp Operations`  
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of lookup operations.

`[-access <Counter with Delta>] - Access Operations`  
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of access operations.

`[-rsym <Counter with Delta>] - ReadSymlink Operations`  
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of readsymlink operations.
[-read <Counter with Delta>] - Read Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of read operations.

[-write <Counter with Delta>] - Write Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of write operations.

[-create <Counter with Delta>] - Create Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of create operations.

[-mkdir <Counter with Delta>] - MkDir Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of mkdir operations.

[-symlink <Counter with Delta>] - SymLink Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of symlink operations.

[-mknod <Counter with Delta>] - MkNod Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of mknod operations.

[-remove <Counter with Delta>] - Remove Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of remove operations.

[-rmdir <Counter with Delta>] - RmDir Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of rmdir operations.

[-rename <Counter with Delta>] - Rename Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of rename operations.

[-link <Counter with Delta>] - Link Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of link operations.

[-rdir <Counter with Delta>] - ReadDir Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of readdir operations.

[-rdirp <Counter with Delta>] - ReadDirPlus Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of readdirplus operations.

[-fsstat <Counter with Delta>] - FsStat Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of fsstat operations.

[-fsinfo <Counter with Delta>] - FsInfo Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of fsinfo operations.

[-pconf <Counter with Delta>] - PathConf Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of pathconf operations.
[-commit <Counter with Delta>] - Commit Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of commit operations.

[-total <Counter64 with Delta>] - Total Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of total NFSv3 operations.

[-null-pct <Counter with Delta>] - Percent Null Ops
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of null operations.

[-gattr-pct <Counter with Delta>] - Percent GetAttr Ops
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of getattr operations.

[-sattr-pct <Counter with Delta>] - Percent SetAttr Ops
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of setattr operations.

[-lookup-pct <Counter with Delta>] - Percent LookUp Ops
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of lookup operations.

[-access-pct <Counter with Delta>] - Percent Access Ops
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of access operations.

[-rsym-pct <Counter with Delta>] - Percent ReadSymlink Ops
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of readsymlink operations.

[-read-pct <Counter with Delta>] - Percent Read Ops
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of read operations.

[-write-pct <Counter with Delta>] - Percent Write Ops
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of write operations.

[-create-pct <Counter with Delta>] - Percent Create Ops
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of create operations.

[-mkdir-pct <Counter with Delta>] - Percent MkDir Ops
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of mkdir operations.

[-symln-pct <Counter with Delta>] - Percent SymLink Ops
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of symlink operations.

[-mknod-pct <Counter with Delta>] - Percent MkNod Ops
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of mknod operations.

[-remove-pct <Counter with Delta>] - Percent Remove Ops
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of remove operations.
[-rmdir-pct <Counter with Delta>] - Percent RmDir Ops
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of rmdir operations.

[-rename-pct <Counter with Delta>] - Percent Rename Ops
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of rename operations.

[-link-pct <Counter with Delta>] - Percent Link Ops
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of link operations.

[-rdir-pct <Counter with Delta>] - Percent ReadDir Ops
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of readdir operations.

[-rdirp-pct <Counter with Delta>] - Percent ReadDirPlus Ops
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of readdirplus operations.

[-fsstat-pct <Counter with Delta>] - Percent FsStat Ops
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of fsstat operations.

[-fsinfo-pct <Counter with Delta>] - Percent FsInfo Ops
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of fsinfo operations.

[-pconf-pct <Counter with Delta>] - Percent PathConf Ops
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of pathconf operations.

[-commit-pct <Counter with Delta>] - Percent Commit Ops
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of commit operations.

Examples
The following example displays statistics about the NFSv3 operations for a node named node1:

```
cluster1::> statistics nfs show-v3 -node node1
```

**statistics nfs show-v4**

Display NFSv4 statistics

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**

The `statistics nfs show-v4` command displays the following statistics about the NFSv4 operations on each node in the cluster:

- Result of the operations (success or failure)
- Total number of null operations
- Total number of compound operations
- Total number of access operations
• Total number of close operations
• Total number of commit operations
• Total number of create operations
• Total number of delegpurge operations
• Total number of delegret operations
• Total number of getattr operations
• Total number of getfh operations
• Total number of link operations
• Total number of lock operations
• Total number of lockt operations
• Total number of locku operations
• Total number of lookup operations
• Total number of lookupp operations
• Total number of nverify operations
• Total number of open operations
• Total number of openattr operations
• Total number of openconf operations
• Total number of opendowng operations
• Total number of putfh operations
• Total number of putpubfh operations
• Total number of putrootfh operations
• Total number of read operations
• Total number of readdir operations
• Total number of readlink operations
• Total number of remove operations
• Total number of rename operations
• Total number of renew operations
• Total number of restorefh operations
• Total number of savefh operations
• Total number of secinfo operations
• Total number of setattr operations
• Total number of setcliid operations
• Total number of setcliidconf operations
• Total number of verify operations
- Total number of write operations
- Total number of rellockown operations
- Total number of total operations
- Percent of null operations
- Percent of compound operations
- Percent of access operations
- Percent of close operations
- Percent of commit operations
- Percent of create operations
- Percent of delegpurge operations
- Percent of delegret operations
- Percent of getattr operations
- Percent of getfh operations
- Percent of link operations
- Percent of lock operations
- Percent of lockt operations
- Percent of locku operations
- Percent of lookup operations
- Percent of lookupp operations
- Percent of nverify operations
- Percent of open operations
- Percent of openattr operations
- Percent of openconf operations
- Percent of opendowng operations
- Percent of putfh operations
- Percent of putpubfh operations
- Percent of putrootfh operations
- Percent of read operations
- Percent of readdir operations
- Percent of readlink operations
- Percent of renew operations
- Percent of restorefh operations
- Percent of savefh operations
- Percent of secinfo operations
- Percent of setattr operations
- Percent of setcliid operations
- Percent of setCliidconf operations
- Percent of verify operations
- Percent of write operations
- Percent of rellockown operations

This command is designed to be used to analyze performance characteristics and to help diagnose issues.

**Parameters**

{[-fields <fieldname>, ...]

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

| [-instance ] |

If you specify the `-instance` parameter, the command displays detailed information about all fields.

[-node {<nodename>|local}] - Node

If you specify this parameter, the command displays NFSv4 statistics only for the specified node.

[-result {success|failure|all}] - Result

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified result (success/failure/all).

[-null <Counter with Delta>] - Null Procedure

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of null operations.

[-cmpnd <Counter with Delta>] - Compound Procedure

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of compound operations.

[-access <Counter with Delta>] - Access Operations

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of access operations.

[-close <Counter with Delta>] - Close Operations

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of close operations.

[-commit <Counter with Delta>] - Commit Operations

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of commit operations.

[-create <Counter with Delta>] - Create Operations

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of create operations.

[-delpur <Counter with Delta>] - Delegpurge Operations

If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of delegpurge operations.
[\texttt{-delrtn <Counter with Delta>\texttt{]} - Delegret Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of delegret operations.

[\texttt{-gattr <Counter with Delta>\texttt{]} - GetAttr Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of getattr operations.

[\texttt{-getfh <Counter with Delta>\texttt{]} - GetFh Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of getfh operations.

[\texttt{-link <Counter with Delta>\texttt{]} - Link Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of link operations.

[\texttt{-lock <Counter with Delta>\texttt{]} - Lock Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of lock operations.

[\texttt{-lockt <Counter with Delta>\texttt{]} - LockT Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of lockt operations.

[\texttt{-locku <Counter with Delta>\texttt{]} - LockU Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of locku operations.

[\texttt{-lookup <Counter with Delta>\texttt{]} - Lookup Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of lookup operations.

[\texttt{-lookpp <Counter with Delta>\texttt{]} - LookupP Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of lookpp operations.

[\texttt{-nverfy <Counter with Delta>\texttt{]} - Nverify Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of nverify operations.

[\texttt{-open <Counter with Delta>\texttt{]} - Open Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of open operations.

[\texttt{-opattr <Counter with Delta>\texttt{]} - OpenAttr Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of openattr operations.

[\texttt{-opconf <Counter with Delta>\texttt{]} - OpenConf Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of openconf operations.

[\texttt{-opndg <Counter with Delta>\texttt{]} - OpenDowng Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of opendowng operations.

[\texttt{-putfh <Counter with Delta>\texttt{]} - PutFh Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of putfh operations.
[--putpfh <Counter with Delta>] - PutPubFh Operations
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of putpubfh operations.

[--putrfh <Counter with Delta>] - PutRootFh Operations
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of putrootfh operations.

[--read <Counter with Delta>] - Read Operations
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of read operations.

[--readdr <Counter with Delta>] - ReadDir Operations
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of readdir operations.

[--rlink <Counter with Delta>] - ReadLink Operations
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of readlink operations.

[--remove <Counter with Delta>] - Remove Operations
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of remove operations.

[--rename <Counter with Delta>] - Rename Operations
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of rename operations.

[--renew <Counter with Delta>] - Renew Operations
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of renew operations.

[--restfh <Counter with Delta>] - RestoreFh Operations
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of restorefh operations.

[--savefh <Counter with Delta>] - SaveFh Operations
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of savefh operations.

[--secinf <Counter with Delta>] - SecInfo Operations
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of secinfo operations.

[--sattr <Counter with Delta>] - SetAttr Operations
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of setattr operations.

[--sclid <Counter with Delta>] - SetCliId Operations
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of setcliid operations.

[--scidc <Counter with Delta>] - SetCliIdConf Operations
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of setcliidconf operations.

[--verify <Counter with Delta>] - Verify Operations
   If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of verify operations.
[-write <Counter with Delta>] - Write Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of write operations.

[-relown <Counter with Delta>] - RelLockOwn Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of rellockown operations.

[-total <Counter64 with Delta>] - Total Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified number of total nfsv4 operations.

[-null-pct <Counter with Delta>] - Percent Null Procedure
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of null operations.

[-cmpnd-pct <Counter with Delta>] - Percent Compound Procedure
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of compound operations.

[-access-pct <Counter with Delta>] - Percent Access Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of access operations.

[-close-pct <Counter with Delta>] - Percent Close Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of close operations.

[-commit-pct <Counter with Delta>] - Percent Commit Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of commit operations.

[-create-pct <Counter with Delta>] - Percent Create Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of create operations.

[-delpur-pct <Counter with Delta>] - Percent Delegpurge Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of delegpurge operations.

[-delrtn-pct <Counter with Delta>] - Percent Delegret Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of delegret operations.

[-gattr-pct <Counter with Delta>] - Percent GetAttr Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of getattr operations.

[-getfh-pct <Counter with Delta>] - Percent GetFh Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of getfh operations.

[-link-pct <Counter with Delta>] - Percent Link Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of link operations.

[-lock-pct <Counter with Delta>] - Percent Lock Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of lock operations.
[-lockt-pct <Counter with Delta>] - Percent LockT Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of lockt operations.

[-locku-pct <Counter with Delta>] - Percent LockU Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of locku operations.

[-lookup-pct <Counter with Delta>] - Percent Lookup Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of lookup operations.

[-lookpp-pct <Counter with Delta>] - Percent LookupP Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of lookpp operations.

[-nverfy-pct <Counter with Delta>] - Percent Nverify Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of nverify operations.

[-open-pct <Counter with Delta>] - Percent Open Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of open operations.

[-opattr-pct <Counter with Delta>] - Percent OpenAttr Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of openattr operations.

[-opconf-pct <Counter with Delta>] - Percent OpenConf Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of openconf operations.

[-opndg-pct <Counter with Delta>] - Percent OpenDowng Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of opendowng operations.

[-putfh-pct <Counter with Delta>] - Percent PutFh Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of putfh operations.

[-putpfh-pct <Counter with Delta>] - Percent PutPubFh Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of putpubfh operations.

[-putrfh-pct <Counter with Delta>] - Percent PutRootFh Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of putrootfh operations.

[-read-pct <Counter with Delta>] - Percent Read Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of read operations.

[-readdr-pct <Counter with Delta>] - Percent ReadDir Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of readdir operations.

[-rlink-pct <Counter with Delta>] - Percent ReadLink Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of readlink operations.
[-remove-pct <Counter with Delta>] - Percent Remove Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of remove operations.

[-rename-pct <Counter with Delta>] - Percent Rename Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of rename operations.

[-renew-pct <Counter with Delta>] - Percent Renew Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of renew operations.

[-restfh-pct <Counter with Delta>] - Percent RestoreFh Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of restorefh operations.

[-savefh-pct <Counter with Delta>] - Percent SaveFh Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of savefh operations.

[-secinf-pct <Counter with Delta>] - Percent SecInfo Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of secinfo operations.

[-sattr-pct <Counter with Delta>] - Percent SetAttr Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of setattr operations.

[-sclid-pct <Counter with Delta>] - Percent SetCliId Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of setcliid operations.

[-scidc-pct <Counter with Delta>] - Percent SetCliIdConf Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of setcliidconf operations.

[-verify-pct <Counter with Delta>] - Percent Verify Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of verify operations.

[-write-pct <Counter with Delta>] - Percent Write Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of write operations.

[-relown-pct <Counter with Delta>] - Percent RelLockOwn Operations
If you specify this parameter, the command displays statistics only about the node or nodes that have the specified percentage of rellockown operations.

**Examples**
The following example displays statistics about the NFSv4 operations for a node named node1:

```
cluster1::> statistics nfs show-v4 -node node1
```

```
<table>

statistics node commands
System utilization metrics for each node in the cluster

statistics node show
System utilization metrics for each node in the cluster

Availability: This command is available to cluster administrators at the admin privilege level.

Description
This command continuously displays performance data for nodes at a regular interval. The command output displays data in the following columns:

- Node - node name.
- CPU (%) - CPU utilization.
- Total Ops - total number of operations per second.
- Latency (ms) - average latency for an operation in milliseconds.

Parameters
[-node <nodename> | local] - Node
Selects the node for which you want to display performance data.
[-sort-key <text>] - Column to Sort By
   If this parameter is specified, the command displays statistics sorted by the specified column.

-interval <integer> - Interval
   Specifies, in seconds, the interval between statistics updates. The default setting is 5 seconds.

-iterations <integer> - Iterations
   Specifies the number of iterations the command runs before terminating. The default setting is 1. If the number
   is 0 (zero), the command continues to run until you interrupt it by pressing Ctrl-C.

-max <integer> - Maximum Number of Instances
   Specifies the maximum number of aggregates to display. The default setting is 25.

Examples
The following example displays node statistics:

```
cluster1::> statistics node show
cluster1 : 12/31/2013 16:00:04

   CPU *Total Latency
  Node (%)  Ops  (ms)
   ------  ---  -------
 node2  76  113      -
nodel  58  10      -

[...]
```

statistics oncrpc commands

Monitor ONC RPC statistics

statistics oncrpc show-rpc-calls

Display ONC RPC Call Statistics

Availability: This command is available to cluster administrators at the advanced privilege level.

Description

Attention: This command is deprecated and will be removed in a future major release.

The statistics oncrpc show-rpc-calls command displays information about the Open Network Computing Remote
Procedure Call (ONC RPC) calls performed by the nodes of a cluster.

Parameters

[-fields <fieldname>, ...]
   If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified
   field or fields. You can use ‘-fields ?’ to display the fields to specify.

[-instance]
   If you specify the -instance parameter, the command displays detailed information about all fields.

[-node <nodename> | local] - Node
   Use this parameter to display information only about the RPC calls performed by the node you specify.
[--protocol {TCP|UDP}] - Transport Protocol

Use this parameter to display information only about the RPC calls performed using the network protocol you specify.

[--badproc <Counter with Delta>] - Bad Procedure Calls

Use this parameter to display information only about the RPC calls that have the number of bad procedure calls you specify. Bad procedure calls are RPC requests that contain invalid procedure numbers and cannot be completed.

[--badlen <Counter with Delta>] - Bad Length Calls

Use this parameter to display information only about the RPC calls that have the number of bad length calls you specify.

[--badhdr <Counter with Delta>] - Bad Header Calls

Use this parameter to display information only about the RPC calls that have the number of bad header calls you specify.

[--badcalls <Counter with Delta>] - Bad Calls

Use this parameter to display information only about the RPC calls that have the number of bad calls you specify.

[--badprogcalls <Counter with Delta>] - Bad Program Calls

Use this parameter to display information only about the RPC calls that have the number of bad program calls you specify.

[--calls <Counter64 with Delta>] - Total Calls

Use this parameter to display information only about the RPC calls that have the total number of bad calls you specify.

statistics port commands

Displays performance data for ports

statistics port fcp commands

FCP port interface throughput and latency metrics

statistics port fcp show

FCP port interface throughput and latency metrics

Availability: This command is available to cluster administrators at the admin privilege level.

Description
This command continuously displays performance data for FCP ports at a regular interval. The command output displays data in the following columns:

- Port - port name.
- Read Ops - read operations per second.
- Write Ops - write operations per second.
- Other Ops - other operations per second.

Parameters

- `-port <text>` - Port
  Selects the port for which you want to display performance data.

- `-sort-key <text>` - Column to Sort By
  If this parameter is specified, the command displays statistics sorted by the specified column.

  `-interval <integer>` - Interval
  Specifies, in seconds, the interval between statistics updates. The default setting is 5 seconds.

  `-iterations <integer>` - Iterations
  Specifies the number of iterations the command runs before terminating. The default setting is 1. If the number is 0 (zero), the command continues to run until you interrupt it by pressing Ctrl-C.

  `-max <integer>` - Maximum Number of Instances
  Specifies the maximum number of ports to display. The default setting is 25.

Examples

The following example displays port statistics:

```
cluster1::> statistics port fcp show
cluster1 : 12/31/2013 16:00:04
*Total Read Write
Port     Ops  Ops   Ops  Ops
----- -------- ---- --------
```
Performance Preset configuration directory

The preset directory

Directory contains commands to delete, modify, import, and display Performance Preset configurations and their details. A Performance Preset declares a list of one or more Performance Object names and a list of Performance Counter names (for each Object). Preset configurations expected to be used by the Performance Archive will specify sample periods for each Counter, declaring how often each Counter is to be archived. To create a new Performance Preset configuration, the `perf-preset-create` API or `statistics preset import` command must be used.

`statistics preset delete`

Delete an existing Performance Preset

**Availability:** This command is available to `cluster` administrators at the `advanced` privilege level.

**Description**

Deletes a performance preset configuration and all of its associated details.

**Parameters**

`-preset <text>` - Preset Name

Specifies the name of the performance presets that you want to delete.

**Examples**

```
cluster1:*> statistics preset show
  Preset Name: asup-event
  Preset UUID: 55c03699-01db-11e2-8e3e-123478563412
  Comment: The event-based AutoSupport Data ONTAP Performance Archive preset configuration. This preset configuration is used whenever an event-based AutoSupport is triggered.
  Privilege: diagnostic

4 entries were displayed.

**Statistics Preset Modify**

Modify an existing Performance Preset

**Availability:** This command is available to cluster administrators at the **advanced** privilege level.
Description
Modifies an existing performance preset configuration. The command modifies the global properties of a preset, but does not modify the details of the preset, such as specific objects and counters sampled.

Parameters
- **-preset <text>* - Preset Name
  Name of the performance preset to be modified.

  [-**new-name <text>**] - New Preset Name
  Set preset name to the given new name.

  [-**comment <text>**] - Preset Description
  Set comment to the given value.

  [-**privilege <PrivilegeLevel>*] - Preset Privilege Level
  Set privilege level at which this preset can be viewed or modified to the given value. Possible values: admin, advanced, diagnostic.

Examples
```
cluster1::*> statistics preset show
  Preset Name: delta
  Preset UUID: 7a04f19d-02a7-11e2-8e40-123478563412
  Comment: custom preset description
  Privilege: diagnostic
  Read-Only: false
  Archive Enabled: false
  Generation ID: 0
1 entry was displayed.

cluster1::*> statistics preset modify -preset delta -comment "new comment"

cluster1::*> statistics preset show
  Preset Name: delta
  Preset UUID: 7a04f19d-02a7-11e2-8e40-123478563412
  Comment: new comment
  Privilege: diagnostic
  Read-Only: false
  Archive Enabled: false
  Generation ID: 0
1 entry was displayed.
```

**statistics preset show**
Display information about Performance Presets

**Availability:** This command is available to cluster administrators at the advanced privilege level.

**Description**
Displays information about performance preset configurations.

**Parameters**

{ [-**fields <fieldname>,...**] |
  Selects which performance preset attributes to display. |

| [-**instance **] |
  Shows details of all attributes of performance preset configuration. |

- **-preset <text>* - Preset Name
  Selects the performance presets that match the specified preset name. |
[-comment <text>] - Preset Description
Selects the performance presets that match the specified comment.

[-privilege <PrivilegeLevel>] - Preset Privilege Level
Selects the performance presets that are available with the specified privilege.

[-is-read-only [true|false]] - Is Preset Read-Only?
Selects the performance presets that are read-only (true) or are not read-only (false). Read-only presets cannot
be modified.

[-store <text>] - Name of Store Where Data is Saved
Selects the store where data is saved.

---

**Examples**

```
cluster1:*> statistics preset show

<table>
<thead>
<tr>
<th>Preset Name</th>
<th>Privilege</th>
<th>Read-Only</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>aggregate_overview</td>

**Performance Preset Detail directory**

The detail directory

Directory contains commands to display Performance Preset Details for Performance Preset configurations.

**statistics preset detail show**

Display information about Performance Preset Details

**Availability:** This command is available to `cluster` administrators at the `advanced` privilege level.

**Description**

Displays the specific details of each preset, including the objects sampled, the counter sample periods, and the counters
sampled.

**Parameters**

```
{ [-fields <fieldname>, ...]

[-instance ]

[-preset <text>] - Preset Name
Selects the performance preset details that match the specified preset name.

[-object <text>] - Performance Object
Selects the performance preset details that match the specified object name.
```
[-sample-period <sample_period>] - Archive Sample period

Selects the performance preset details that are collected at the specified sample period.

[-counter-set <text>, ...] - Performance Counter Name Set

Selects the performance preset details that match the specified counters in the counter set. Use "|" to separate multiple counters.

[-instance-filters <text>, ...] - Performance Instance Filters

Selects the performance preset details that match the specified instance filters. Use "|" to separate multiple instance filters. This field is reserved for future use.

### Examples

```
cluster1::*> statistics preset detail show

<table>
<thead>
<tr>
<th>Preset Name</th>
<th>Object</th>
<th>Period</th>
<th>Counter Set</th>
<th>Filters</th>
</tr>
</thead>
<tbody>
<tr>
<td>asup-event</td>
<td>aggregate</td>
<td>lw</td>
<td>instance_name, node_name, process_name,...</td>
<td>parent_host, total_transfers, user_reads, user_writes, cp_reads, user_read_blocks, user_write_blocks, cp_read_blocks, wv_fsid, wv_vol_type, wv_fsinfo_fs_version, wv_volinfo_fs_options,</td>
</tr>
</tbody>
</table>

...  
```

### statistics qtree commands

Qtree I/O operation rates

### statistics qtree show

Qtree I/O operation rates

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

**Description**
This command continuously displays performance data for qtrees at a regular interval. The command output displays data in the following columns:

- **Qtree** - Qtree name.
- **Vserver** - Vserver name.
- **Volume** - Volume name.
- **NFS Ops** - NFS operations per second.
- **CIFS Ops** - CIFS operations per second.
• Internal Ops - Internal operations per second.
• Total Ops - Total number of operations per second.

**Parameters**

[-qtree <text>] - Qtree
  Selects the qtree for which you want to display performance data. The qtree name has to be given in the format "vol_name/qtree_name"

[-vserver <vserver name>] - Vserver
  Selects the Vserver for which you want to display performance data.

[-volume <text>] - Volume
  Selects the volume for which you want to display performance data.

[-sort-key <text>] - Column to Sort By
  If this parameter is specified, the command displays statistics sorted by the specified column.

-<interval <integer>> - Interval
  Specifies, in seconds, the interval between statistics updates. The default setting is 5 seconds.

-<iterations <integer>> - Iterations
  Specifies the number of iterations the command runs before terminating. The default setting is 1. If the number is 0 (zero), the command continues to run until you interrupt it by pressing Ctrl-C.

-<max <integer>> - Maximum Number of Instances
  Specifies the maximum number of qtrees to display. The default setting is 25.

**Examples**

The following example displays qtree statistics:

```
C1_sti20-vsim-ucs429g_1520278254::> statistics qtree show
C1_sti20-vsim-ucs429g_1520278254 : 3/14/2018 15:40:46

NFS  CIFS  Internal  *Total
------  -------  ---------  ------
    ops  ops    ops      ops
----------- ------- ------- --- ---- -------- ------
 flexvol/qt1  vs0  flexvol  7   0      0      7
  dp_vol/qt9  vs0   dp_vol  7   0      0      7
  dp_vol/qt8  vs0   dp_vol  7   0      0      7

[...]
```

**statistics samples directory**

The samples directory

The `statistics samples` commands provide information about samples.

**statistics samples delete**

Delete statistics samples

**Availability:** This command is available to `cluster` and `Vserver` administrators at the `advanced` privilege level.

**Description**

This command deletes samples that you created using the `statistics start` command.
Parameters
-vserver <vserver name> - Vserver
Selects the Vserver for which you want to delete the sample. The default Vserver is admin Vserver.

-sample-id <text> - Sample Identifier
Specifies the sample that you want to delete. This is a required parameter.

Examples
The following example deletes the sample "smpl_1":

cluster1:*> statistics samples delete -sample-id smpl_1

statistics start on page 766

statistics samples show
Display statistics samples

Availability: This command is available to cluster and Vserver administrators at the advanced privilege level.

Description
This command displays information about the samples that you created using the statistics start command.

Parameters
{ [-fields <fieldname>, ...]
   If you specify the -fields <fieldname>, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

   [-describe ]}
Displays detailed information about each sample.

[-vserver <vserver name>] - Vserver
Selects the samples that match this parameter value. If you omit this parameter, the command displays details for all samples.

[-sample-id <text>] - Sample Identifier
Selects the samples that match this parameter value. If you do not specify this parameter, the command will display information about all the samples in the cluster.

Examples
The following example displays information for sample "smpl_1":

cluster1:*> statistics samples show -sample-id smpl_1

<table>
<thead>
<tr>
<th>Vserver</th>
<th>Sample ID</th>
<th>Start Time</th>
<th>Stop Time</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>cluster-d1</td>
<td>smpl_1</td>
<td>09/13 18:06:46</td>
<td>-</td>
<td>Ready</td>
</tr>
</tbody>
</table>

The following example displays detailed information for sample "smpl_1":
cluster1::*> statistics samples show -sample-id smpl_1 -describe

Vserver: vs1
Sample ID: smpl_1
Object: processor
Instance: -
Counter: -
Start Time: 09/13 18:06:46
Stop Time: -
Status: Ready       - -
Privilege: admin

**statistics settings commands**

Manage the displaying of statistics

**statistics settings modify**

Modify settings for the statistics commands

**Availability:** This command is available to cluster administrators at the advanced privilege level.

**Description**

This command modifies the settings for all of the *statistics* commands.

**Parameters**

- `-display-rates {true|false}]` - Display Rates
  Specifies whether the *statistics* commands display rate counters in rates/second. The default is true.
- `-client-stats {enabled|disabled}]` - Collect Per-Client Statistics
  Specifies whether *statistics* commands display per-client information. The default is disabled.
  **Note:** If you enable this setting, you might significantly impact system performance.
- `-counter-display-units {B|KB|MB|GB}]` - Counter Display Units
  Specifies display units for the counters. The default setting is MB.
- `-display-count-exponent <integer>]` - Display Count Exponent
  Specifies display exponent value for the counters representing counts. The default setting is 3 (thousand).

**Examples**

The following example sets the value of the `display-rates` parameter to false:

```
cluster1::*> statistics settings modify -display-rates false
```

statistics system commands

System utilization metrics for the cluster

### statistics system show

System utilization metrics for the cluster

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**
This command continuously displays performance data for cluster at a regular interval. The command output displays data in the following columns:

- System - cluster name.
- CPU (%) - CPU utilization.
- Total Ops - total number of operations per second.
- Latency(ms) - average latency for an operation in milliseconds.

**Parameters**

- `-system <text>` - System
  
  Selects the cluster for which you want to display performance data.

- `-sort-key <text>` - Column to Sort By
  
  If this parameter is specified, the command displays statistics sorted by the specified column.

- `-interval <integer>` - Interval
  
  Specifies, in seconds, the interval between statistics updates. The default setting is 5 seconds.
-iterations <integer> - Iterations

Specifies the number of iterations the command runs before terminating. The default setting is 1. If the number is 0 (zero), the command continues to run until you interrupt it by pressing Ctrl-C.

-max <integer> - Maximum Number of Instances

Specifies the maximum number of systems to display. The default setting is 25.

Examples

The following example displays system statistics:

```
cluster1::> statistics system show
cluster1 : 12/31/2013 16:00:04

                  CPU *Total Latency
                   System (%)   Ops   (ms)
                   --------   -----   ----
                Cluster    76     113     -

[...]```

statistics top commands

Displays performance data for statistically tracked objects

statistics top client commands

Most active NFS and CIFS clients

statistics top client show

Most active NFS and CIFS clients

Availability: This command is available to cluster administrators at the admin privilege level.

Description

This command continuously displays performance data for the top NFS and CIFS clients at a regular interval. The command output displays data in the following columns:

- Client - client name.
- Vserver - vserver name.
- Node - node name.
- Total Ops - total number of operations per second.
- Total (Bps) - total throughput in bytes per second.

Parameters

- `-node <nodename>|local` - Node
  Selects the node for which you want to display performance data.

- `-sort-key <text>` - Column to Sort By
  If this parameter is specified, the command displays statistics sorted by the specified column.

- `-interval <integer>` - Interval
  Specifies, in seconds, the interval between statistics updates. The default setting is 5 seconds.
---iterations <integer> - Iterations

Specifies the number of iterations the command runs before terminating. The default setting is 1. If the number is 0 (zero), the command continues to run until you interrupt it by pressing Ctrl-C.

---max <integer> - Maximum Number of Instances

Specifies maximum number of top clients to display. The default setting is 10.

### Examples

The following example displays top client statistics:

```bash
cluster1::> statistics top client show
cluster-1 : 12/31/1969 16:00:04

<table>
<thead>
<tr>
<th>Client</th>
<th>Vserver</th>
<th>Node</th>
<th>Total Ops</th>
<th>Total (Bps)</th>
</tr>

```

---statistics top file commands

Most actively accessed files

---statistics top file show

Most actively accessed files

**Availability:** This command is available to cluster administrators at the `admin` privilege level.

**Description**

This command continuously displays performance data for top files at a regular interval. The command output displays data in the following columns:

- **File** - file name.
- **Volume** - volume name.
- **Vserver** - vserver name.
- **Aggregate** - aggregate name.
- **Node** - node name.
- **Total Ops** - total number of operations per second.
- **Total (Bps)** - total throughput in bytes per second.

**Parameters**

- **[-node <nodename> | local]** - Node
  
  Selects the node for which you want to display performance data.

- **[-sort-key <text>]** - Column to Sort By
  
  If this parameter is specified, the command displays statistics sorted by the specified column.

- **-interval <integer>** - Interval
  
  Specifies, in seconds, the interval between statistics updates. The default setting is 5 seconds.
-iterations <integer> - Iterations

Specifies the number of iterations the command runs before terminating. The default setting is 1. If the number is 0 (zero), the command continues to run until you interrupt it by pressing Ctrl-C.

-max <integer> - Maximum Number of Instances

Specifies maximum number of top files to display. The default setting is 10.

Examples
The following example displays top files statistics:

```
cluster1::> statistics top file show
cluster-1 : 12/31/1969 16:00:04

+-----------------------------+-----------------+-------+---+-----------------------+-------+-------+--------+-------+
| File                       | Volume          | Vserver | Aggregate | Node          | Ops   | (Bps) |

statistics volume commands

Volume throughput and latency metrics

statistics volume show

Volume throughput and latency metrics

Availability: This command is available to cluster and Vserver administrators at the admin privilege level.

Description
This command continuously displays performance data for volumes at a regular interval. The command output displays data in the following columns:

- Volume - volume name.
- Vserver - vserver name.
- Aggregate - aggregate name.
- Total Ops - total number of operations per second.
- Read Ops - read operations per second.
- Write Ops - write operations per second.
- Other Ops - other operations per second.
- Read (Bps) - read throughput in bytes per second.
- Write (Bps) - write throughput in bytes per second.
- Latency(us) - average latency for an operation in microseconds.

Parameters

[-volume <text>] - Volume

Selects the volume for which you want to display performance data.
-\texttt{vserver <vserver name>} - Vserver

Selects the vserver for which you want to display performance data.

-\texttt{aggregate <text>} - Aggregate

Selects the aggregate for which you want to display performance data.

-\texttt{sort-key <text>} - Column to Sort By

If this parameter is specified, the command displays statistics sorted by the specified column.

-\texttt{interval <integer>} - Interval

Specifies, in seconds, the interval between statistics updates. The default setting is 5 seconds.

-\texttt{iterations <integer>} - Iterations

Specifies the number of iterations the command runs before terminating. The default setting is 1. If the number is 0 (zero), the command continues to run until you interrupt it by pressing Ctrl-C.

-\texttt{max <integer>} - Maximum Number of Instances

Specifies the maximum number of volumes to display. The default setting is 25.

\begin{tabular}{|l|l|l|l|l|l|l|l|}

\begin{flushleft}
\textbf{statistics vserver show}
\end{flushleft}

Vserver throughput and latency metrics

\textbf{Availability:} This command is available to cluster administrators at the \texttt{admin} privilege level.

\textbf{Description}

This command continuously displays performance data for Vservers at a regular interval. The command output displays data in the following columns:

- Vserver - Vserver name.
- Total Ops - total number of operations per second.
- Read Ops - read operations per second.
- Write Ops - write operations per second.
- Other Ops - other operations per second.
- Read (Bps) - read throughput in bytes per second.
• Write (Bps) - write throughput in bytes per second.
• Latency(us) - average latency for an operation in microseconds.

Parameters

[-vserver <vserver name>] - Vserver
    Selects the vserver for which you want to display performance data.

[-sort-key <text>] - Column to Sort By
    If this parameter is specified, the command displays statistics sorted by the specified column.

-interval <integer> - Interval
    Specifies, in seconds, the interval between statistics updates. The default setting is 5 seconds.

-iterations <integer> - Iterations
    Specifies the number of iterations the command runs before terminating. The default setting is 1. If the number
    is 0 (zero), the command continues to run until you interrupt it by pressing Ctrl-C.

-max <integer> - Maximum Number of Instances
    Specifies the maximum number of Vservers to display. The default setting is 25.

Examples

The following example displays Vserver statistics:

```
cluster1::> statistics vserver show
cluster1 : 12/31/2013 16:00:04

+-----------------+-----------------+-----------------+-----------------+-----------------+-----------------+-----------------+
| Vserver | Total Ops | Read Ops | Write Ops | Other Ops | Read (Bps) | Write (Bps) | Latency (us) |

| vs2     | 56        | 0        | 11        | 45        | 8192       | 28826       | 47          |
[...]```

statistics workload commands

QoS workload throughput and latency metrics

statistics workload show

QoS workload throughput and latency metrics

Availability: This command is available to cluster administrators at the advanced privilege level.

Description

This command continuously displays performance data for workloads at a regular interval. The command output displays data in
the following columns:

• Workload - workload name.
• Total Ops - total number of operations per second.
• Read Ops - read operations per second.
• Write Ops - write operations per second.
• Other Ops - other operations per second.
- Read (Bps) - read throughput in bytes per second.
- Write (Bps) - write throughput in bytes per second.
- Latency(us) - average latency for an operation in microseconds.

**Parameters**

[-workload <text>] - Workload

Selects the workload for which you want to display performance data.

[-sort-key <text>] - Column to Sort By

If this parameter is specified, the command displays statistics sorted by the specified column.

-interval <integer> - Interval

Specifies, in seconds, the interval between statistics updates. The default setting is 5 seconds.

-iterations <integer> - Iterations

Specifies the number of iterations the command runs before terminating. The default setting is 1. If the number is 0 (zero), the command continues to run until you interrupt it by pressing Ctrl-C.

-max <integer> - Maximum Number of Instances

Specifies the maximum number of workloads to display. The default setting is 25.

**Examples**

The following example displays workload statistics:

```bash
cluster1::> statistics workload show
cluster1 : 12/31/2013 16:00:04

*Total Read Write Other   Read Write Latency
Workload    Ops  Ops   Ops   Ops  (Bps) (Bps)    (us)
--------------- ------ ---- ----- ----- ------ ----- -------
_USERSPACE_APPS     30    1     3     0  30765  8553       0
_WAFI_SCAN     20    0     0     0     0      0       0

[...]
```

**storage-service commands**

Manage Storage Services

**storage-service show**

Display the available storage services

**Availability:** This command is available to cluster and Vserver administrators at the advanced privilege level.

**Description**

This command displays the available storage services.

**Note:** The available storage services are defined by the type of storage making up an aggregate.
Parameters

\{-fields \textless fieldname\textgreater , ...\}

If you specify the \{-fields \textless fieldname\textgreater , ...\} parameter, the command output also includes the specified field or fields. You can use \{-fields ?\} to display the fields to specify.

\{-instance \}\}

If you specify the \{-instance\} parameter, the command displays detailed information about all fields.

\{-vserver \textless vserver name\textgreater \} - Vserver

Selects the available storage services for Vservers that match the parameter value.

\{-storage-service \textless text\textgreater \} - Storage Service

Selects the available storage services whose name matches the parameter value.

\{-description \textless text\textgreater \} - Description

Selects the available storage services whose description matches the parameter value. This field is a text description of the storage service.

\{-expected-iops-per-tb \textless integer\textgreater \} - Expected IOPS per TB

Selects the available storage services whose expected IOPS per TB matches the parameter value. When multiplied by a number of TB, this field yields the number of IOPS nominally guaranteed by the storage service. The multiplier is either the logical used space or the provisioned size of the storage object, depending on the value of \{-expected-iops-allocation\}.

\{-expected-iops-allocation \textless used-space|allocated-space\textgreater \} - Expected IOPS Allocation

Selects the available storage services whose expected IOPS allocation policy matches the parameter value. The allocation policy is either \textit{allocated-space} or \textit{used-space}. When the expected-iops-allocation policy is \textit{allocated-space}, the expected IOPS is calculated based on the size of the storage object. When the expected-iops-allocation policy is set to \textit{used-space}, the expected IOPS is calculated based on the amount of data logically stored in the storage object.

\{-peak-iops-per-tb \textless integer\textgreater \} - Peak IOPS per TB

Selects the available storage services whose peak IOPS per TB matches the parameter value. When multiplied by a number of TB, this field yields the number of IOPS for the maximum Quality of Service (QoS) throttle. The multiplier is either the logical used space or the provisioned size of the storage object, depending on the value of \{-peak-iops-allocation\}.

\{-peak-iops-allocation \textless used-space|allocated-space\textgreater \} - Peak IOPS Allocation

Selects the available storage services whose peak IOPS allocation policy matches the parameter value. The allocation policy is either \textit{allocated-space} or \textit{used-space}. When the peak-iops-allocation policy is \textit{allocated-space}, the peak IOPS is calculated based on the size of the storage object. When the peak-iops-allocation policy is set to \textit{used-space}, the peak IOPS is calculated based on the amount of data logically stored in the storage object.

\{-absolute-min-iops \textless integer\textgreater \} - Absolute Minimum IOPS

Selects the available storage services whose absolute minimum IOPS matches the parameter value. This field is the minimum number of IOPS used as the Quality of Service (QoS) throttle, if larger than the values calculated using the IOPS per TB parameters.

\{-target-latency \textless integer\textgreater \} - Target Latency (ms)

Selects the available storage service whose target latency matches the parameter value.
[-aggr-list <aggregate name>, ...] - Aggregate List

Selects the available storage services whose aggregate list matches the parameter value. The aggregates shown are the only ones used for provisioning when the corresponding Vserver and storage service are selected.

---

### Examples

```
cluster1:*> storage-service show
Vserver   Storage Service       Description
--------- ------------------------ ----------------------------------------------
vs1       extreme               Extreme Performance                               
          performance           Performance                                
          value                 Value                                 
3 entries were displayed.
```

---

### Storage Commands

Manage physical storage, including disks, aggregates, and failover

The `storage` commands enable you to manage physical and logical storage, including disks and storage aggregates. They also enable you to manage storage failover.

---

### Storage aggregate Commands

Manage storage aggregates

The `storage aggregate` command family manages aggregates. The `storage aggregate` commands can create new aggregates, add more disks to an aggregate, delete the existing ones, change aggregate status and apply options to an aggregate. Aggregate commands often affect the volumes contained within aggregates.

An aggregate name can contain letters, numbers, and the underscore character(_), but the first character must be a letter or underscore. A maximum of 100 aggregates can be created on each node.

An aggregate may be online, restricted, iron_restricted, or offline. When an aggregate is offline, no read or write access is allowed. When an aggregate is restricted, certain operations are allowed (parity recomputation or RAID reconstruction) but data access is not allowed.

Aggregates can be in combinations of the following raid status:

- **normal**: The aggregate is in a normal state.
- **copying**: The aggregate is currently the target aggregate of an active aggr copy operation.
- **ironing**: A WAFL consistency check is being performed on this aggregate.
- **degraded**: The aggregate contains at least one degraded RAID group that is not being reconstructed.
- **mirror degraded**: The aggregate is a mirrored aggregate, and one of its plexes is offline or resyncing.
- **growing**: Disks are in the process of being added to the aggregate.
initializing
The aggregate is in the process of being initialized.

invalid
The aggregate does not contain any volume and no volume can be added to it. Typically, this happens after an aborted aggregate copy operation.

needs check
A WAFL consistency check needs to be performed on the aggregate.

partial
The aggregate contains at least one disk, however, two or more disks are missing.

reconstruct
At least one RAID group in the aggregate is being reconstructed.

raid0
The aggregate consists of RAID-0 (no parity) RAID groups (V-Series and NetCache only).

raid4
The aggregate consists of RAID-4 RAID groups.

raid_dp
The aggregate consists of RAID-DP (Double Parity) RAID groups.

raid_tec
The aggregate consists of RAID-TEC (Triple Erasure Code) RAID groups.

redirect
A reallocation process optimized the layout of blocks in the aggregate. You cannot clear this status.

wafl inconsistent
The aggregate has been marked corrupted. Please contact technical support if you see an aggregate in this state.

storage aggregate add-disks
Add disks to an aggregate

Availability: This command is available to cluster administrators at the admin privilege level.

Description
The storage aggregate add-disks command adds disks to an existing aggregate. You must specify the number of disks or provide a list of disks to be added. If you specify the number of disks without providing a list of disks, the system selects the disks.

Parameters
-aggregate <aggregate name> - Aggregate
This parameter specifies the aggregate to which disks are to be added.

[-diskcount <integer>] - Disk Count
This parameter specifies the number of disks that are to be added to the aggregate.

{ [-disktype | -T (ATA | BSAS | FCAL | FSAS | LUN | MSATA | SAS | SSD | VMDISK | SSD-NVM)] - Disk Type
This parameter specifies the type of disk that is to be added. It must be specified with the -diskcount parameter when adding disks to a Flash Pool.
Use this parameter when adding spare SSDs to an aggregate to convert it to a Flash Pool.

**Note:** Only the aggregates marked as **hybrid-enabled** can be converted to Flash Pools. Use `storage aggregate modify` command to mark the aggregate as **hybrid-enabled**.

**Note:** When this parameter is used, disk selection is not influenced by RAID options `raid.mix.hdd.disktype.capacity`, `raid.mix.hdd.disktype.performance`, or `raid.mix.disktype.solid_state`. Only disks of the specified type are considered eligible for selection.

```
[-diskclass | -C (capacity | performance | archive | solid-state | array | virtual)] - Disk Class
```

This parameter specifies the class of disk that is to be added. All disks that belong to the specified class are considered eligible for selection. The possible values are:

- **capacity** = Capacity-oriented, near-line disk types. Includes disk types FSAS, BSAS and ATA.
- **performance** = Performance-oriented, enterprise class disk types. Includes disk types FCAL and SAS.
- **archive** = Archive class SATA disks in multi-disk carrier storage shelves. Includes disk type MSATA.
- **solid-state** = Solid-state drives. Includes disk type SSD and SSD-NVM.
- **array** = Logical storage devices backed by storage arrays and used by Data ONTAP as disks. Includes disk type LUN.
- **virtual** = Virtual disks that are formatted and managed by the hypervisor. Includes disk type VMDISK.

**Note:** When this parameter is used, disk selection is not influenced by RAID options `raid.mix.hdd.disktype.capacity`, `raid.mix.hdd.disktype.performance`, or `raid.mix.disktype.solid_state`.

```
[-chksumstyle <aggrChecksumStyle>] - Checksum Style
```

This parameter specifies the checksum style for the disks to be added to an aggregate. It is not applicable if `-disklist` or `-mirror-disklist` is specified. The possible values are **block** for block checksum and **advanced_zoned** for advanced zoned checksum (AZCS). By default, disks with the same checksum style as the aggregate are selected. This behavior can be overridden by using this parameter to create a mixed checksum aggregate. A mixed checksum aggregate can support only the **block** and **advanced_zoned** checksum styles.

```
[-disksize <integer>] - Disk Size(GB)
```

This parameter specifies the size, in GB, of the disks that are to be added to the aggregate. Disks with a usable size between 90% and 105% of the specified size are selected.

```
[-disklist | -d <disk path name>, ...] - Disks
```

This parameter specifies a list of disks to be added. If you specify the `-disklist` parameter, you cannot further qualify the list of disks to be added by count, checksum style, size or type.

```
[-mirror-disklist <disk path name>, ...] - Disks for Mirrored Plex
```

This parameter specifies a list of mirror disks to be added. It must contain the same number of disks specified in `-disklist` parameter. If you specify the `-mirror-disklist` parameter, you cannot further qualify the list of disks to be added by count, checksum style or type.

```
{ [-ignore-pool-checks [true]] - Don’t Enforce Plex Pool Best Practices
```

The disks in a plex are normally required to come from the same SyncMirror pool. This behavior can be overridden with this parameter when it is set to `true`.

```
[-allow-mixed-rpm | -f [true]] - Allow Disks With Different RPM Values
```

This parameter specifies whether disks that have different RPM values can be added. For example, SAS disks can rotate at 10,000 or 15,000 RPM. If this parameter is set to `true` and a list of disks are provided by using the `-disklist` or `-disklist` parameter, then disks that have different RPM values can be added.
the -disklist parameter, the disks will be added even if the SAS disks you specify have different RPM values. This parameter works similarly for ATA disks, which can rotate at 5,400 or 7,200 RPM.

**Note:** This parameter is applicable only when the -disklist or -mirror-disklist parameter is used.

[-allow-same-carrier [true]] - Allow Same RAID Group Within Carrier

This parameter can be used to allow two disks housed in the same carrier to be in the same RAID group when you add disks to an aggregate.

Having disks in the same carrier in the same RAID group is not desirable because a carrier failure can cause a simultaneous outage for two disks in the same RAID group. You can add a disk to an aggregate that causes this situation, but when an alternate disk becomes available, Data ONTAP automatically initiates a series of disk copy operations to put the disks into different RAID groups. For this reason, you should use this parameter only when necessary. When possible, allow Data ONTAP to choose disks that need to be added to the aggregate.

This parameter affects only the add-disks operation. It is not a persistent attribute of the aggregate.

[[-storage-pool <storage pool name>] - Storage Pool

This parameter specifies the name of the SSD storage pool from which available allocation units are added to a given aggregate. This parameter cannot be used with the -disk-list or -disk-count parameters.

[-allocation-units <integer>] - Allocation Units

This parameter specifies the number of allocation units to be added to a given aggregate from an SSD storage pool. Number of allocation units available and size of each unit can be found using the storage pool show-available-capacity command. This parameter works only when you also use the -storage-pool parameter.

[-simulate | -n [true]] - Simulate Addition of Disks

This parameter is used with the disktype and diskcount parameters to determine which disks would be added without actually performing the addition of disks operation.

[-raidgroup | -g {new|all|<raidgroup>}]} - RAID Group

This parameter enables the administrator to specify which RAID group will receive the added disks. If this parameter is not used, the disks are added to the most recently created RAID group until it is full, then new raid groups are created and filled until all the disks are added. If a RAID group name rgX is specified, the disks are added to that RAID group. If new is specified, the disks are added to a new RAID group, even if the disks would fit into an existing RAID group. If all is specified, the disks are added to existing RAID groups until all existing RAID groups are full. Then Data ONTAP creates one or more new RAID groups and adds the remaining disks to the new groups. If the disk type or checksum style parameters are specified with this parameter, the command operates only on the RAID groups with the matching disk type or checksum style, even if all is specified.

[-cache-raid-group-size <integer>] - RAID Group Size for Cache Tier

This parameter specifies the maximum number of disks that can be included in an SSD RAID group for this aggregate.

**Note:** This parameter is applicable only when adding SSDs for the first time to a hybrid-enabled aggregate. If this parameter is not used when the first SSDs are added to the aggregate, the maximum RAID group size for the SSD cache is set to the default SSD RAID group size for the RAID type of the SSD cache.

[-raidtype | -t {raid_tec|raid_dp|raid4}] - RAID Type

This parameter specifies the type for the new RAID groups that would be created while adding disks to the aggregate. Use this parameter when you add the first RAID group comprised of SSDs to a hybrid-enabled aggregate. The values are raid4 for RAID4, raid_dp for RAID Double Parity, and raid_tec for RAID-TEC. The default value is the type of RAID groups of the aggregate, except for RAID-TEC hybrid-enabled aggregates where the SSD tier will default to raid_dp. An aggregate might include a mix of different RAID types.
Examples
The following example adds 10 disks to an aggregate named aggr0. The disks are added to a RAID group named rg1:

```
cluster1::> storage aggregate add-disks -aggregate aggr0 -diskcount 10 -raidgroup rg1
```

In this example, an aggregate is converted to a Flash Pool aggregate using SSD capacity from a storage pool. The aggregate was created using RAID-DP for the hard disks and the SSDs are added using RAID4.

```
cluster1::> storage aggregate add-disks -aggregate FlashPool -storage-pool SP1 -allocation-units 1 -raidtype raid4
```

`storage aggregate auto-provision`
Recommend and create new aggregates in the cluster

**Availability:** This command is available to cluster administrators at the `admin` privilege level.

**Description**
This command analyzes available spare disks in the cluster, and it provides a recommendation how spare disks should be used to create aggregates according to best practices. The command prints the summary of recommended aggregates including their names and usable size. It then prompts the user whether the aggregates should be created as recommended. On positive response, ONTAP creates aggregates as described in the recommendation.

The command parameters allow to restrict the command to some nodes in the cluster, print more details about recommended aggregates, and to skip the prompt.

**Parameters**

- `-nodes (<nodename> [local], ...)` - List of Nodes
  Comma separated list of node names to which the command applies. If this parameter is not used, the command applies to all nodes in the cluster.

- `-verbose [true]` - Report More Details
  Report additional details about recommended aggregates and spare disks. Per node summary shows number and total size of aggregates to create, discovered spares, and also remaining spare disks and partitions after aggregate creation. RAID group layout shows how spare disks and partitions will be used in new data aggregates to be created. The last table shows spare disks and partitions remaining unused after aggregate creation.

- `-skip-confirmation [true]` - Skip the Confirmation and Create Recommended Aggregates
  When this parameter is used, the command automatically creates the recommended aggregates. When this parameter is not used, the command checks to proceed with aggregate creation or not.

  **Note:** The command is not affected by the CLI session setting: `set -confirmations on/off`. 

Examples

```
cluster1::storage aggregate> auto-provision
Node               New Data Aggregate            Usable Size
------------------ ---------------------------- ------------
node1              node1_SSD_1                        3.66TB
node2              node2_SSD_1                        3.66TB
------------------ ---------------------------- ------------
Total:             2 new data aggregates              7.32TB
```

Do you want to create recommended aggregates? {y|n}: n

```
cluster1::storage aggregate> auto-provision -verbose
```

Per node summary of new aggregates to create, discovered spares, and also remaining spare disks and partitions after aggregate creation:

```
Node               New Aggrs Total New -Discovered Spare- -Remaining Spare-
------------------ ----- ------------ ------ ----------- ------ ----------
node1               1       3.66TB      6          48      1          0
node2               1       3.66TB      6          48      1          0
------------------ ----- ------------ ------ ----------- ------ ----------
Total:               2       7.32TB     12          96      2          0
```

New data aggregates to create with counts of disks and partitions to be used:

```
Node               New Data Aggregate            Usable Size Disks Partitions
------------------ ---------------------------- ------------ ----- ----------
node1              node1_SSD_1                        3.66TB     5         48
node2              node2_SSD_1                        3.66TB     5         48
```

RAID group layout showing how spare disks and partitions will be used in new data aggregates to be created:

```
RAID Group In New Data Aggregate To Be Created          Disk      Usable Disk Or ---Count---
-------------------------------------- ------ ---------- --------- ---- -----
/node1_SSD_1/plex0/rg0                         SSD      81.97GB partition   22      2
/node1_SSD_1/plex0/rg1                         SSD      81.97GB partition   22      2
/node1_SSD_1/plex0/rg2                         SSD      185.5GB disk         3      2
/node2_SSD_1/plex0/rg0                         SSD      81.97GB partition   22      2
/node2_SSD_1/plex0/rg1                         SSD      81.97GB partition   22      2
/node2_SSD_1/plex0/rg2                         SSD      185.5GB disk         3      2
```

Details about spare disks and partitions remaining after aggregate creation:

```
Disk         Device Disk Or   Remaining
Node               Type    Usable Size Partition    Spares
------------------ ------ ------------ --------- ---------
node1              SSD         185.5GB disk              1
node2              SSD         185.5GB disk              1
```

Do you want to create recommended aggregates? {y|n}: y

```
Info: Aggregate auto provision has started. Use the "storage aggregate show-auto-provision-progress" command to track the progress.
```

storage aggregate create

Create an aggregate

Availability: This command is available to cluster administrators at the admin privilege level.

Description

The storage aggregate create command creates an aggregate. An aggregate consists of disks. You must specify the number of disks or provide a list of disks to be added to the new aggregate. If you specify the number of disks without providing a list of disks, the system selects the disks.

When creating an aggregate, you can optionally specify the aggregate's home node, the RAID type for RAID groups on the aggregate, and the maximum number of disks that can be included in a RAID group.

Parameters

-aggregate <aggregate name> - Aggregate

This parameter specifies the name of the aggregate that is to be created.

-chksumstyle <aggrChecksumStyle> - Checksum Style

This parameter specifies the checksum style for the aggregate. The values are block for Block Checksum and advanced_zoned for Advanced Zoned Checksum (AZCS).

-diskcount <integer> - Number Of Disks

This parameter specifies the number of disks that are to be included in the aggregate, including the parity disks. The disks in this newly created aggregate come from the pool of spare disks. The smallest disks in this pool are added to the aggregate first, unless you specify the -disksize parameter.

-diskrpm | -R <integer> - Disk RPM

This parameter specifies the RPM of the disks on which the aggregate is to be created. The possible values include 5400, 7200, 10000, and 15000.

-disksize <integer> - Disk Size(GB)

This parameter specifies the size, in GB, of the disks on which the aggregate is to be created. Disks with a usable size between 90% and 105% of the specified size are selected.

-disktype | -T {ATA | BSAS | FCAL | FSAS | LUN | MSATA | SAS | SSD | VMDISK | SSD-NVM} - Disk Type

This parameter specifies the type of disk on which the aggregate is to be created.

Note: When this parameter is used, disk selection is not influenced by RAID options raid.mix.hdd.disktype.capacity, raid.mix.hdd.disktype.performance, or raid.mix.disktype.solid_state. Only disks of the specified type are considered eligible for selection.

-diskclass | -C {capacity | performance | archive | solid-state | array | virtual} - Disk Class

This parameter specifies the class of disks on which the aggregate is to be created. All disks that belong to the specified class are considered eligible for selection. The possible values are:

- capacity = Capacity-oriented, near-line disk types. Includes disk types FSAS, BSAS and ATA.
- performance = Performance-oriented, enterprise class disk types. Includes disk types FCAL and SAS.
- archive = Archive class SATA disks in multi-disk carrier storage shelves. Includes disk type MSATA.
- solid-state = Solid-state drives. Includes disk type SSD and SSD-NVM.
array = Logical storage devices backed by storage arrays and used by Data ONTAP as disks. Includes disk type LUN.

virtual = Virtual disks that are formatted and managed by the hypervisor. Includes disk type VMDISK.

**Note:** When this parameter is used, disk selection is not influenced by RAID options

raid.mix.hdd.disktype.capacity, raid.mix.hdd.disktype.performance, or

raid.mix.disktype.solid_state.

```
-m [true] - Mirror
```

This parameter specifies that the new aggregate be mirrored (have two plexes). If this parameter is set to true, the specified disks are split between the two plexes. By default, the new aggregate will not be mirrored. You cannot use the -mirror parameter when supplying a specific list of disks with either the -disklist or -mirror-disklist parameters.

```
-pool <aggrSparePool> - Spare Pool
```

This parameter specifies the SyncMirror pool to be used to supply the disks for the aggregate. Valid values are Pool0 or Pool1.

```
-d <disk path name>, ... - Disks for First Plex
```

This parameter specifies a list of disks to be added to the new aggregate. If you specify the -disklist parameter, you cannot further qualify the list of disks to be added by count, checksum style, type, size, or RPM. You cannot use the -disklist parameter when the -mirror parameter is set to true.

```
-mirror-disklist <disk path name>, ... - Disks for Mirrored Plex
```

This parameter specifies a list of mirror disks to be added to the new mirrored aggregate. It must contain the same number of disks specified in -disklist parameter. If you specify the -mirror-disklist parameter, you cannot further qualify the list of disks to be added by count, checksum style, type, size, or RPM. You cannot use the -mirror-disklist parameter when the -mirror parameter is set to true.

```
-ignore-pool-checks [true] - Don't Enforce Plex Pool Best Practices
```

The disks in a plex are normally required to come from the same SyncMirror pool. This behavior can be overridden with this parameter when it is set to true. This option cannot be used when the -mirror option is set to true.

```
-allow-mixed-rpm [true] - Allow Disks With Different RPM Values
```

This parameter specifies whether the aggregate can contain disks that have different RPM values. For example, SAS disks can rotate at 10,000 or 15,000 RPM. If this parameter is set to true and a list of disks are provided by using the -disklist parameter, the aggregate will be created even if the SAS disks you specify have different RPM values. This parameter works similarly for ATA disks, which can rotate at 5,400 or 7,200 RPM.

```
-allow-same-carrier [true] - Allow Same RAID Group Within Carrier
```

This parameter can be used to allow two disks housed in the same carrier to be in the same RAID group when you add disks to an aggregate.

Having disks in the same carrier in the same RAID group is not desirable because a carrier failure can cause a simultaneous outage for two disks in the same RAID group. You create an aggregate with this characteristic, but when an alternate disk becomes available, Data ONTAP automatically initiates a series of disk copy operations to put the disks into different RAID groups. For this reason, you should use this parameter only when necessary. When possible, allow Data ONTAP to choose the disks from which to create the aggregate.

This parameter affects only the aggregate creation operation. It is not a persistent attribute of the aggregate.

```
-node {<nodename>|local} - Node
```

This parameter specifies the home node for the aggregate. If this parameter is not specified, Data ONTAP selects the node where the aggregate is created.

```
-maxraidsize | -s <integer> - Max RAID Size
```

This parameter specifies the maximum number of disks that can be included in a RAID group.
[raidtype] - RAID Type

This parameter specifies the type for RAID groups on the aggregate. The values are raid4 for RAID4, raid_dp for RAID Double Parity, and raid_tec for RAID Triple-Erasure-Code. The default setting is raid_dp unless the disks are HDDs with a capacity larger than 4 TB, in which case the default will be raid_tec. This parameter is not needed for array LUNs because they are always created with the raid0 raidtype. raid4 is not compatible with shared disks unless the shared disks belong to a storage pool.

[simulate [true]] - Simulate Aggregate Provisioning Operation

This option simulates the aggregate creation and prints the layout of the new aggregate.

[force-small-aggregate [true]] - Force the Creation of a Small Aggregate (privilege: advanced)

This parameter can be used to force the creation of a 2-disk RAID4 aggregate, or a 3-disk or 4-disk RAID-DP aggregate.

[is-autobalance-eligible {true|false}] - Is Eligible for Auto Balance Aggregate (privilege: advanced)

This specifies whether the aggregate will be considered by the Auto Balance Aggregate feature. If the Auto Balance Aggregate feature is not used, this field is not used. When this parameter is set to true the Auto Balance Aggregate feature might recommend moving volumes to or from this aggregate in order to balance system workload. When this parameter is set to false the aggregate will not be considered as a destination for the Auto Balance Aggregate feature allowing for predictability in data placement. The default value is false.

[snaplock-type] - SnapLock Type

This parameter specifies the type of SnapLock aggregate to be created. In order to create a SnapLock Compliance aggregate, specify compliance. To create a SnapLock Enterprise aggregate, specify enterprise.

[autobalance-unbalanced-threshold-percent <integer>] - Threshold When Aggregate Is Considered Unbalanced (%) (privilege: advanced)

This parameter specifies the space used threshold percentage that will cause the Auto Balance Aggregate feature to consider an aggregate as unbalanced.

[autobalance-available-threshold-percent <integer>] - Threshold When Aggregate Is Considered Balanced (%) (privilege: advanced)

This parameter specifies the threshold percentage which will determine if an aggregate is a target destination for a move. The Auto Balance Aggregate feature will attempt to move volumes from an unbalanced aggregate until it is under this percentage.

[encrypt-with-aggr-key {true|false}] - Enable Aggregate level Encryption

This parameter specifies the data encryption policy for the contained volumes. If this parameter is set to true, then by default, the volumes created in this aggregate will be encrypted, using the aggregate level encryption keys.

Examples

The following example creates an aggregate named aggr0 on a home node named node0. The aggregate contains 20 disks and uses RAID-DP. The aggregate contains regular FlexVol volumes:

```
cluster1::> storage aggregate create -aggregate aggr0 -nodes node0
   -diskcount 20 -raidtype raid_dp -volume-style flex
```

The following example creates an aggregate named aggr0 on a home node named node0. The aggregate contains the disks specified and uses RAID-DP:

```
cluster1::> storage aggregate create -aggregate aggr0 -nodes node0
   -disklist 1.0.15,1.0.16,1.0.17,1.0.18,1.0.19 -raidtype raid_dp
```
The following example creates an aggregate named aggr0 on a home node named node0. The aggregate contains 20 disks of size 6 TB and of type FSAS and uses RAID-TEC:

```
cluster1::> storage aggregate create -aggregate aggr0 -nodes node0 -diskcount 20 -raidtype raid_tec -disksize 6000 -disktype FSAS
```

The following example creates a mirrored aggregate named aggr0 on the local node. The aggregate contains 10 disks in each plex:

```
cluster1::> storage aggregate create -aggregate aggr0 -mirror -diskcount 20
```

**Related references**

- *storage raid-options* on page 1062

**storage aggregate delete**

Delete an aggregate

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**

The *storage aggregate delete* command deletes a storage aggregate. The command fails if there are volumes present on the aggregate. If the aggregate has an object store attached to it, then in addition to deleting the aggregate the command deletes the objects in the object store as well. No changes are made to the object store configuration as part of this command.

**Parameters**

- `-aggregate <aggregate name>` - Aggregate
  
  This parameter specifies the aggregate that is to be deleted.

- `[-preserve-config-data [true]]` - Delete Physical Aggregate but Preserve Configuration Data (privilege: advanced)
  
  Deletes the physical aggregate, but preserves the aggregate configuration data. The aggregate must not have any disks associated with it. If the parameter `-preserve-config-data` is specified without a value, the default value is `true`; if this parameter is not specified, the default value is `false`.

**Examples**

The following example deletes an aggregate named aggr1:

```
cluster1::> storage aggregate delete -aggregate aggr1
```

**storage aggregate mirror**

Mirror an existing aggregate

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

**Description**

The *storage aggregate mirror* command adds a plex to an existing unmirrored aggregate. You can specify a list of disks to be used for the mirrored plex. If you do not specify the disks, the system automatically selects the disks based on the aggregate’s existing plex.
Parameters

- \texttt{aggregate <aggregate name> - Aggregate}
  
  This parameter specifies the aggregate to mirror.

- \texttt{allow-mixed-rpm [-f [true]] - Allow Disks With Different RPM Values}
  
  This parameter specifies whether disks that have different RPM values can be used. For example, SAS disks can rotate at 10,000 or 15,000 RPM. If this parameter is set to \texttt{true} and a list of disks are provided by using the \texttt{-mirror-disklist} parameter, the disks will be added even if the SAS disks you specify have different RPM values. This parameter works similarly for ATA disks, which can rotate at 5,400 or 7,200 RPM.

  \textbf{Note:} This parameter is only applicable when the \texttt{-mirror-disklist} parameter is used.

- \texttt{mirror-disklist [-d <disk path name>, ...] - Disks for Mirrored Plex}
  
  This parameter specifies a list of disks to be used for the plex to be added. It must contain the same number of disks as the existing plex of the unmirrored aggregate specified using the \texttt{-aggregate} parameter.

- \texttt{ignore-pool-checks [true] - Don't Enforce Plex Pool Best Practices}
  
  For maximum reliability, all disks from a plex should come from the same SyncMirror pool, and the disks for the second plex should all come from the other pool. If needed, this behavior can be overridden by setting this parameter to \texttt{true}. This parameter can be used only with the \texttt{-mirror-disklist} parameter.

- \texttt{allow-same-carrier [-f [true]] - Allow Same RAID Group Within Carrier}
  
  This parameter can be used to allow two disks housed in the same carrier to be in the same RAID group for a mirrored aggregate. Having disks in the same carrier in the same RAID group is not desirable, because a carrier failure can cause a simultaneous outage for two disks in the same RAID group. For this reason, this configuration is not allowed by default. This restriction can be overridden by setting this parameter to \texttt{true}.

  \textbf{Note:} This parameter is accepted only when the \texttt{-mirror-disklist} parameter is used.

- \texttt{simulate [-n [true]] - Simulate Mirroring of an Existing Aggregate}
  
  This option simulates the mirroring of an existing aggregate and prints the layout of the new plex.

\begin{Verbatim}
Examples

The following example mirrors an unmirrored aggregate aggr1:

\texttt{cluster1::> storage aggregate mirror -aggregate aggr1}

The following example mirrors an unmirrored aggregate aggr1. The specified disks are used for the new plex.

\texttt{cluster1::> storage aggregate mirror -aggregate aggr1 -mirror-disklist 1.2.12, 1.2.14, 1.2.16}
\end{Verbatim}

\textbf{storage aggregate modify}

Modify aggregate attributes

\textbf{Availability:} This command is available to \textit{cluster} administrators at the \textit{admin} privilege level.

\textbf{Description}

The \texttt{storage aggregate modify} command can be used to modify attributes of an aggregate such as RAID type and maximum RAID group size.

Changing the RAID type immediately changes the RAID group type for all RAID groups in the aggregate.

Changing the maximum RAID size does not cause existing RAID groups to grow or to shrink; rather, it affects the size of RAID groups created in the future, and determines whether more disks can be added to the RAID group that was most recently created.
Parameters

- **aggregate <aggregate name>** - Aggregate

  This parameter specifies the storage aggregate that is to be modified.

- **-disktype | -T (ATA | BSAS | FCAL | FSAS | LUN | MSATA | SAS | SSD | VMDISK | SSD-NVM)** - Disk Type

  This parameter specifies either the HDD tier or the SSD tier when changing the RAID type of a Flash Pool. If the HDD tier is composed of more than one type of disk, specifying any of the disk types in use causes that tier to be modified.

- **-free-space-realloc (on|off)** - Free Space Reallocation

  This parameter specifies whether free space reallocation is enabled on the aggregate.

  Free space reallocation optimizes the free space in an aggregate immediately before Data ONTAP writes data to the blocks in that aggregate.

  The default setting is **off**.

- **-ha-policy (sfo|cfo)** - HA Policy

  This parameter specifies the high-availability policy to be used in the context of a root recovery procedure. Do not modify this setting unless directed to do so by a customer support representative.

- **-percent-snapshot-space <percent>** - Space Reserved for Snapshot Copies

  This parameter is used to set the space reserved for Snapshot copies to the specified value. For example, to set the snapshot reserve to 5%, you should enter `-percent-snapshot-space 5`.

- **-space-nearly-full-threshold-percent <percent>** - Aggregate Nearly Full Threshold Percent

  This optionally specifies the percentage at which the aggregate is considered nearly full, and above which an EMS warning will be generated. The default value is 95%. The maximum value for this option is 99%. Setting this threshold to 0 disables the aggregate nearly full space alerts.

- **-space-full-threshold-percent <percent>** - Aggregate Full Threshold Percent

  This optionally specifies the percentage at which the aggregate is considered full, and above which a critical EMS error will be generated. The default value is 98%. The maximum value for this option is 100%. Setting this threshold to 0 disables the aggregate full space alerts.

- **-hybrid-enabled (true|false)** - Hybrid Enabled

  If the hybrid-enabled option is set to "true", the aggregate is marked as hybrid_enabled, that is, the aggregate can contain a mix of SSDs and HDDs (Hard Disk Drives, e.g., SAS, SATA, and/or FC). By default, aggregates cannot be marked "hybrid_enabled" if the aggregate contains FlexVols that cannot be write cached. A FlexVol cannot be write-cached if it is part of an aggregate created in Data ONTAP 7. Use `-force-hybrid-enabled` to over-ride this behavior.

- **-force-hybrid-enabled | -f [true]** - Force Marking of Aggregate as Hybrid Enabled

  By default, aggregates cannot be marked "hybrid_enabled" if the aggregate contains FlexVols that cannot be write cached. A FlexVol cannot be written unless it is part of an aggregate created in Data ONTAP 7. Use `-force-hybrid-enabled` to over-ride this behavior. Note that read caching will be enabled on these FlexVols, but write caching will be disabled. Setting this parameter to `true` would mark the aggregate as hybrid_enabled; this means that the aggregate can contain a mix of SSDs and HDDs (Hard Disk Drives, for example, SAS, SATA and/or FC). This parameter is used to force marking aggregates which have FlexVols that cannot be write cached as hybrid enabled. FlexVols in the aggregate marked as hybrid enabled using this parameter which cannot participate in write-caching will only have read-caching enabled. All other FlexVols in the aggregate can participate in both read and write caching.

- **-maxraidsize | -s <integer>** - Max RAID Size

  This parameter specifies the maximum number of disks that can be included in a RAID group for this aggregate.

  **Note:** For Flash Pools, this option controls the maximum size of the HDD RAID groups.
[\[-\text{cache-raid-group-size } \langle\text{integer}\rangle]\] - Flash Pool SSD Tier Maximum RAID Group Size

This parameter specifies the maximum number of disks that can be included in a SSD RAID group for this Flash Pool.

Note: This parameter is applicable only for Flash Pools.

[\[-\text{raidtype } -t \{\text{raid_tec}|\text{raid_dp}|\text{raid4}\}\] - RAID Type

This parameter specifies the RAID type for RAID groups on the aggregate. The possible values are \text{raid4} for RAID4, \text{raid_dp} for RAID-DP, and \text{raid_tec} for RAID-TEC. If you change the RAID type from RAID4 to RAID-DP, each RAID group allocates a spare disk for the group's second parity disk and begins a reconstruction process. If you change the RAID type from RAID-DP to RAID-TEC, each RAID group allocates a spare disk for the group's third parity disk and begins a reconstruction process. Changing the RAID type from RAID4 to RAID-TEC or vice-versa is not supported. To change the RAID type from RAID4 to RAID-TEC, first change from RAID4 to RAID-DP and then to RAID-TEC.

[\[-\text{resyncsnaptime } \langle\text{integer}\rangle]\] - SyncMirror Resync Snapshot Frequency in Minutes

This parameter sets the mirror resynchronization snapshot frequency to be the given number of minutes. The default value is 60 (minutes).

[\[-\text{state } \langle\text{aggregate state}\rangle]\] - State

This deprecated parameter specifies the state of the aggregate. The possible values are as follows:

• online - Immediately sets the aggregate online. All volumes on the aggregate are set to the state they were in when the aggregate was taken offline or restricted. The preferred command to bring an aggregate online is \text{storage aggregate online}.

• offline - Takes an aggregate offline. You cannot take an aggregate offline if any of its volumes are online. The preferred command to take an aggregate offline is \text{storage aggregate offline}.

• restricted - Restricts the aggregate. You cannot restrict an aggregate if any of its volumes are online. The preferred command to restrict an aggregate is \text{storage aggregate restrict}.

[\[-\text{is-autobalance-eligible } \langle\text{true}|\text{false}\rangle]\] - Is Eligible for Auto Balance Aggregate (privilege: advanced)

This specifies whether the aggregate is considered by the Auto Balance Aggregate feature. If the Auto Balance Aggregate feature is not used, this field is not used. When this parameter is set to \text{true} the Auto Balance Aggregate feature might recommend moving volumes to or from this aggregate in order to balance system workload. When this parameter is set to \text{false} the aggregate will not be considered as a destination for the Auto Balance Aggregate feature allowing for predictability in data placement. The default value is \text{false}.

[\[-\text{autobalance-unbalanced-threshold-percent } \langle\text{integer}\rangle]\] - Threshold When Aggregate Is Considered Unbalanced (%) (privilege: advanced)

This parameter sets the space used threshold percentage that will cause the Auto Balance Aggregate feature to consider an aggregate as unbalanced.

[\[-\text{autobalance-available-threshold-percent } \langle\text{integer}\rangle]\] - Threshold When Aggregate Is Considered Balanced (%) (privilege: advanced)

This parameter sets the threshold percentage which will determine if an aggregate is a target destination for a move. The Auto Balance Aggregate feature will attempt to move volumes from an unbalanced aggregate until it is under this percentage.

[\[-\text{resync-priority } \langle\text{high (fixed)}|\text{high}|\text{medium}|\text{low}\rangle\] - Resynchronization Priority

This parameter specifies the new resynchronization priority value for the specified aggregate. This field cannot be modified for unmirrored or Data ONTAP system aggregates.

Possible values for this parameter are:

• high: Mirrored data aggregates with this priority value start resynchronization first.
medium: Mirrored data aggregates with this priority value start resynchronization after all the system aggregates and data aggregates with 'high' priority value have started resynchronization.

low: Mirrored data aggregates with this priority value start resynchronization only after all the other aggregates have started resynchronization.

[-single-instance-data-logging {off|on}] - Enable SIDL
This parameter specifies whether Single Instance Data Logging feature is enabled on the aggregate and the constituent volumes on the aggregate. This feature improves user write performance by optimizing the amount of data nvlogged by user writes on platforms where NVRAM and secondary storage are of same media type.

[-is-inactive-data-reporting-enabled {true|false}] - Inactive Data Reporting Enabled
This parameter specified whether the reporting of how much user data is inactive should be enabled on the aggregate and volumes on the aggregate. This parameter is not allowed on FabricPools.

[-encrypt-with-aggr-key {true|false}] - Enable Aggregate level Encryption
This parameter specifies that the volumes within the new aggregate can be encrypted with aggregate keys. If this parameter is set to true, the aggregate will support encryption with aggregate keys.

[-force-disable-encrypt-with-aggr-key [true]] - Force disable NAE. Skip aggregate snapshot check.
